Lectures and Addresses.

Lectures on Diseases of the Kidneys.

Delivered at the College of Physicians and Surgeons.

By Francis Delafield, M.D.,
Professor of Pathology and Practical Medicine.

Lecture I.

Chronic congestion of the kidneys.

Gentlemen: The first of the diseases of the kidneys that we will consider is the so-called "chronic congestion of the kidneys." This lesion of the kidneys is not peculiar to the kidneys, but is similar to what is found in certain of the other viscera as a result of chronic venous congestion. When any one of the viscera becomes the seat of a chronic venous congestion from some mechanical cause, as from an organic disease of the heart, the result is, in the first place, to produce a constant oversupply of venous blood to the part, and, in the second place, to produce at the same time too small a supply of arterial blood. When a viscus, therefore, is in a condition of chronic congestion, it is always supplied with too little arterial blood, but, on the other hand, with too much venous blood. In this condition a viscus may remain almost any length of time without any further structural changes taking place, and there is a great difference in individual cases as to how much functional disturbance may result from this chronic congestion. In some cases the viscus may be congested thus for a long time without producing any interference with its functions, while in others, after a short time, sufficient changes will take place to induce functional disturbances.

When this venous congestion of a viscus has lasted a sufficient length of time, then we have other changes taking place which were not at first developed. In the first place, there is a development of a chronic inflammation, which varies in character with the viscous in which it is developed, and with this inflammation there will soon be changes also in the capillary vessels and arteries. The lumen of the capillaries will then be found to be dilated, and the capillaries themselves increased in length and their walls thickened. There will also be continual thickening of the walls of the arteries, while their lumen will not be changed, but will remain of the same size.

In the case of the kidneys we have at first a chronic congestion alone, and then, after some length of time, inflammatory changes may be added which may be referred to the epithelium of the tubules, and especially of those tubules found in the cortical portion of the kidney. In other cases the chronic inflammation may be more decided, and then not only will there be changes in the epithelium lining the tubules, but there will also be a production of new connective tissue and changes in the Malpighian bodies, and, it may be, in the arteries of the viscous also.

While the kidney remains in this condition of chronic congestion it is increased in size and firmness, its capsule is non-adherent, its surface is smooth after stripping the capsule off, and, if we cut the kidney open, we will find that it is uniformly congested, and it has a purplish or deep red color, from the large amount of blood contained in the veins; and this congestion is more marked in the pyramidal than in the cortical portion, and the consistence of the whole kidney is very much harder than it should be.

When there is added to this chronic congestion an inflammatory swelling of the epithelium of the tubules, then the kidney will be enlarged, and especially the cortical portion, and stripping off the capsule will leave the surface smooth and hard, but the epithelium of the convoluted tubes will be swollen and granular, and broken down in different ways.

When, again, the inflammatory process is not confined to the epithelial lining of the tubes, but has extended to the stroma of the kidney, we find a different appearance in the kidney. The organ is in some of these cases larger than normal, but in others it is diminished in size, though it still maintains its stony hardmess. The capsule does not come off so easily as before, leaving a smooth surface behind, but it is now adherent, and, when stripped off, it carries some of the cortical substance with it, and so leaves the surface irregular and nodular. On cutting into the kidney, the cortical portion will be found to be of natural thickness, or else somewhat diminished. If you examine it minutely, you will find changes have taken place in the tubules of the cortical portion, and there are also patches of new connective tissue scattered about, and changes in the Malpighian bodies.

In other cases the gross appearance of the organ is different. The kidney is increased in size, the capsule is non-adherent, the surface is smooth after stripping off the capsule, and, on cutting into it, instead of presenting the appearance of other varieties of congested kidneys, it does not look like these at all, but the cortical portion is white, and not red and congested, while the pyramids are more red, and the whole organ resembles very closely the large white kidney of chronic diffuse nephritis. I have been used to calling this the large white kidney of chronic cardiac disease, for I believe its cause to be in all cases an organic disease of the heart. In these kidneys there will be found well-marked changes in the epithelium of the tubules and in the stroma, and a very decided thickening of the arteries, especially those in the cortical portion. The most common cause of such changes in the kidney is, as I have said, organic disease of the heart. Any well-marked valvular lesion of the heart interfering with the circulation is capable of inducing this condition. A simple dilatation of the heart without any valvular lesion may also induce it, or an aneurysm of the aorta, or a chronic pericarditis, with a large effusion of fluid into the pericardial sac, or an emphysema of the lung, or any tumor pressing upon the larger veins. Some of the cases of the so-called albuminuria of pregnancy are examples of the chronic congestion due to disturbance of the circulation, because of the pressure of the pregnant uterus upon the veins. But of all these causes heart disease is very much the most common, and after that comes emphysema of the lungs, and then pregnancy.

17287
We find often enough, by comparing the histories of different patients and by the examination of kidneys after death, that a very marked degree of congestion may exist for a long time without producing any change in the urine and without the patients presenting any symptoms whatever. We have examples of this in some cases of sudden occurrence of a hydro-pneumothorax. A patient may get a hydro-pneumothorax from a sudden perforation of the lung and live on for two weeks or so after, and then die; and in some of these cases we find in the kidneys a very marked chronic congestion indeed, which has evidently been developed only since the hydro-pneumothorax set in, and yet there have been no changes observed in the urine, and no symptoms of the kidney disorder have been manifested. So, too, in the case of patients with organic disease of the heart who are carried off by some sudden accident, such as by asphyxia or some traumatic cause, we find this condition of congestion in the kidneys after death when there have been no changes during life referable to the urine and no symptoms of kidney disease. So we must admit the existence of a form of chronic congestion of the kidney with no functional disturbances to show it during life. In other cases there will be symptoms of organic disease of the heart or of emphysema of the lungs or other disorders for some length of time, and then at length changes will appear in the urine. As a result of pregnancy, these changes do not appear usually until the later months, i.e., until after the seventh month, and more frequently not until the eighth, ninth, or tenth month will you observe changes in the urine and other symptoms of this disease.

The changes found in the urine in all cases are these: In the first place, the urine should contain some albumin, and, together with the albumin, casts. If the condition is one of simple chronic congestion alone, without any structural changes in the kidneys, then the amount of albumin in the urine is very small, but yet large enough to be detected by the ordinary tests, and in these cases the number of casts in the urine is also very small, and ordinarily there are present only small hyaline casts. When to the chronic congestion are added structural changes in the kidneys, then the amount of albumin in the urine is increased and the casts are more constant in appearance and in larger numbers, and they are not of the hyaline variety only, but also granular, and nucleated casts are found.

As to the quantity of urine excreted there is a great variation in different cases. In some it is diminished quite early in the attack, while there are yet no symptoms; but, instead of passing forty or fifty ounces a day, they only pass twenty or twenty-five ounces. Others will pass the full amount of urine, or some even more—i.e., from fifty to seventy ounces in the twenty-four hours. But in nearly all cases, when they get to near the close of the disease and the other symptoms become more marked, then the urine is usually diminished, and it may be very much diminished, so that only ten or twelve ounces will be passed in the twenty-four hours, or in thirty-six or forty-eight hours, and at last there may not be any urine at all. So, though the quantity of urine in different cases varies very much during the course of the disease, yet there are but few that get on toward the close without there being a diminution in the amount passed.

The specific gravity of the urine is not much changed if the condition is only that of a chronic congestion of the kidneys. But when to this are added structural changes in the organ, then the specific gravity may become very small, as in the case of a chronic diffuse nephritis.

Besides these changes in the urine, we find, in almost all cases, symptoms referable to the lungs. A cough is apt to be developed which is dependent not on the kidney lesion, but on the old cardiac disease which existed first, or on an old emphysema of the lungs; and it is accompanied, as a rule, with a more or less profuse expectoration of mucus, pus, or blood. There is also present in nearly all cases a marked degree of dyspnoea, and it is apt to be very severe, and to prevent the patient from lying down or from sleeping well at night. It depends partly on the heart condition and partly on the condition of the lungs if there is an emphysema, or upon the presence of fluid in the pleural cavity, if any such exists; but in most cases it is none of these, but rather that peculiar nervous dyspnoea that belongs to a variety of the disorders of the kidneys, and is very distressing and uncomfortable to meet with.

Symptoms referable to the stomach also occur. After a time the appetite is lost, and there is likely to be more or less nausea and vomiting. Cerebral symptoms are sometimes developed. There is often a very distressing and continuous headache, very decided restlessness, a good deal of anxiety, and an inability to sleep, and this last symptom is aggravated so much by the dyspnoea that the patient can not lie down, but if he sleeps at all it must be while sitting up in a chair. At a later period, delirium and convulsions may come on, and these may alternate or be succeeded by coma.

The nutrition of the patient is affected at first only slowly, but after a time more rapidly, and then there is loss of flesh and of strength, with a steadily increasing anaemia. So the patient goes on growing gradually worse and worse, and these symptoms becoming constantly more and more evident.

When the chronic congestion of the kidneys succeeds an ordinary condition of organic heart disease, or an emphysema of the lungs, then there will be at first only the symptoms belonging to this condition of the heart or lungs, and these will exist for a considerable length of time without attracting any unusual attention. But, after the lapse of some time, it will be found that the patient is getting worse, and the disturbance of the heart's action is becoming more and more decided, or the emphysematous symptoms are becoming more marked than before. Then the cough and the dyspnoea become worse and worse, and a change takes place in the patient's whole condition; his nutrition suffers, and he loses strength rapidly; the anaemia becomes more and more decided, and disturbances of the stomach, with uncontrollable vomiting, are apt to make themselves evident; then the patient develops cerebral symptoms and dropsy, and finally dies either in a condition of extreme exhaustion, or with very marked dropsy, or from an attack of dyspnoea that can not be removed, or
in an attack of convulsions, or else in a comatose condition, or it may be suddenly and unexpectedly. Different patients vary widely as to the rapidity with which they get worse. Some get worse constantly during a period of several weeks, while others develop dangerous symptoms within a few days. They also differ much as to their ability to emerge from a critical condition when they have once passed into it. A considerable number will not get better at all, but grow constantly worse and worse until they die. But, on the other hand, not infrequently this is not the case; but the patient, after remaining in this condition for a few days or a few weeks, will then get gradually better, and return to a condition of comparative health and comfort. This may continue for some months, and then the patient is apt to have another similar attack. This may be recovered from for a time, and then another may occur, and so on until there have been a number of such attacks; finally in one of these the patient will die. So, no matter how sick a patient seems, even though he has a number of successive convulsions and is apparently moribund, you can never be sure but that he will yet get better, and return to a condition of comparative comfort for a time.

In that form of chronic congestion which is due to the presence of a pregnant uterus in the abdominal cavity, the woman is usually well enough until the later months of pregnancy—i.e., until the eighth, ninth, or tenth lunar month. Then, if the urine is examined from day to day, as it ought to be in all cases of pregnancy, it will be found usually that there are albumin and casts in the urine before the development of any of the other symptoms of a kidney lesion. This is not always the case, but in the larger number the appearance of albumin and casts, with a diminution in the production of urine, will be the first evidence of kidney disturbance in pregnancy. The other symptoms, when they do appear, are, in the first place, sometimes simply a change in the appearance of the woman. Her face usually becomes paler than is natural, and it may be of an unnaturally livid color, or deeply congested, and sometimes pallor alternates with a congestion of the skin. Then, in other women, the first symptom is the sudden development of a persistent and distressing headache, or, it may be, obstinate vomiting sets in, or edema of the legs and a general dropsy. In others the first symptom may be an attack of convulsions, succeeded by or alternating with a state of partial or complete unconsciousness. Whichever of these symptoms comes first, the symptom most apt to be developed and most to be dreaded is convulsions, coming on one after another and succeeded by coma, or successive convulsions, with a condition of unconsciousness between.

Some of these patients will die from this condition of the kidneys, and when they do they are especially apt to die in a convolution, or else they do not emerge from the coma succeeding a convolution. But in a very large number of cases the result is much better than this, especially if labor can be induced and delivery accomplished. Then, although the woman is still sometimes left in a dangerous condition for several days, yet after that the symptoms subside, and she gets better rapidly, and for years after there will be no change in the urine, and no further evidences of renal disease.

In the treatment of all cases of this disease the great object is directed toward regulating the condition of the circulation, for it is upon this that the venous congestion depends. The degree of success you will have in relieving this venous congestion will depend upon the cause that produces it. The greater the mechanical interference with the circulation, the more difficulty you will have. When there is too much blood in the veins and too little in the arteries, there are several different ways of trying to restore the natural proportions. The simplest way is merely to abstract a certain amount of blood from the venous circulation—that is, to bleed from one of the larger veins. In this way you may relieve the venous congestion to a greater or less degree, and then, as a result of this, there will generally be a better action of the heart, which will cause a filling up of the arteries. This method is especially serviceable in those cases where the chronic congestion occurs in connection with the state of pregnancy. In these cases, bleeding from the arm is often found to be productive of good results, and often the expulsion of the child, with the consequent loss of blood from the veins of the uterus, acts in the same way by diminishing the amount of blood in the systemic veins, and this alone will generally be sufficient to answer the purposes of bleeding. But, if for any reason you cannot immediately induce labor and extract the child, then it is proper to take blood from the arm in considerable amount. Another means we can employ to diminish the amount of blood in the veins and increase it in the arteries is, by simply increasing the force of the heart's action by causing the ventricles to contract more vigorously and forcibly than before. As we thus increase the propelling power from behind we increase the amount of blood in the arteries, and at the same time diminish the amount in the veins. This is the plan we usually adopt in cases due to cardiac disease, emphysema of the lungs, aneurysm of the aorta, pericarditis with effusion into the pericardial sac, and the like. In order to accomplish this end, there are two drugs that seem to have more effect than any others over this condition. These are, in the first place, digitalis, a drug that has been in use a number of years, and the effects of which we understand moderately well. Another drug acting in the same way is convallaria. This is a medicine that has only been used for a moderate length of time, and our knowledge of it is less extensive than of digitalis. Whenever you give either of these drugs for this purpose, you should do it with a definite idea in your mind of what you desire to accomplish. When you give digitalis, you should not do it simply because you have read or heard somewhere that digitalis is good for heart disease or for kidney disease, but in order to make the two ventricles of the heart contract more vigorously and forcibly, for it does produce this result. For this purpose the best preparation is the fluid extract, and that prepared by Squibb is the most reliable. You may give this, beginning, according to the age, strength, and condition of the patient, in doses of from two to five drops every three hours, and then watch its effect on the heart's action and the pulse, and see if there is any increase in the production of urine. If the urine is increased, this
shows you that you have increased the amount of arterial blood being thrown into the kidneys, and have diminished the quantity of venous blood contained in them. If you find that the dose you began with is not sufficient to accomplish this, then increase it and carry it up so that you give five, or ten, or even fifteen and twenty drops every two or three hours, according to its effect on the heart and urinary secretion. There are, however, some patients who are unable to take digitalis in any form, for they get its poisonous effects before it manifests its peculiar action on the heart. Here we may fall back upon the fluid extract of convallaria, in doses of from twenty drops to a drachm given every two or three hours, being guided by its action on the heart. This, then, is the second way of trying to relieve the venous congestion of the kidneys by increasing the heart’s action. There is still another method that may be employed for obtaining the same result, and that is by causing a dilatation of the capillaries and small arteries, for then the blood can pass through them more readily, and so the balance of the circulation will be restored and you will get rid of the venous congestion. To accomplish this, we have two drugs which are very efficient—nitrre of amyl and nitro-glycerin. Their effect in dilating the capillaries and small arteries is very rapid and decided. Nitre of amyl may be given by inhalation in doses of from three to five drops, and repeated every six, four, or three hours, as needed. Nitro-glycerin is usually given internally in a one-per-cent. solution in alcohol, one drop of which diluted with water is the dose, and this may be repeated every six, four, three, or two hours, according to its effect. In quite a good many cases you will get good results by combining the two plans I have last mentioned—that is, by increasing the force of the heart’s action and dilating the capillaries, and often you will get better results from this treatment than by attempting to carry out only one indication. These, then, are the only means at our command for restoring the circulation to its natural condition. This is the object that you would first try to accomplish, but, in addition, you would try to do something to relieve some of the various symptoms which help in making patients so very uncomfortable—I refer to the sleeplessness, restlessness, and dyspnea especially. If you can relieve these, you will make the patient comparatively comfortable. For this purpose the one drug that is of most service is opium, and it is the only one that has much effect. You need not hesitate to use it, even though the patient is passing only a small amount of urine. But in these cases you must begin with small doses and watch their effect, and see whether the urine is passed in the same quantities as before, and what its influence is over the restlessness and sleeplessness. You will often find in this way that it can be well borne, and many can take ten to twelve minims of Magendie’s solution every three or four hours. But in other cases a single such hypodermic as a starting dose may cause death within two hours. If it is well borne, you should give enough to induce sleep and make the patient comfortable. In bad cases, which do not tend to recovery at all, but go on to a fatal termination, the dyspnea may not be controllable by any dose of opium, and then it seems to be no more than fair to allow the patients to inhale ether or chloroform in small quantities at intervals, so as to keep them slightly under its influence during the last few days of life, for otherwise they would suffer for days with the dyspnea which no amount of opium seems to relieve, and then would finally die exhausted.

As to the diet of these patients, they are usually fed to best advantage on fluid forms of food, such as milk and beef-tea and the like, and if they have much disturbance of the stomach, then a little lime-water, or some of the alkalies, or a little oxalate of cerium may be added to the milk. If the skin is very dry, sometimes the induction of a diaphoresis will make them more comfortable for a time. The bowels should be kept open and a little loose. This, then, is the ordinary way of managing these cases: first, by trying to remove the cause which induces this condition in the kidneys, and, second, by attempting to relieve the accompanying symptoms of sleeplessness, restlessness, and dyspnea, and finally by attention to the diet, and to the condition of the stomach, skin, and bowels.

Original Communications.

SOLID TUMORS OF BOTH OVARIAS, WITH A FIBROID POLYPUS OF THE UTERUS—DIAGNOSIS WITH THE AID OF THE MICROSCOPE.

REMOVAL OF BOTH TUMORS WITH THE UTERUS.*

BY MATTHEW D. MANN, A.M., M.D.,
PROFESSOR OF OBSTETRICS AND GYNECOLOGY IN THE UNIVERSITY OF BUFFALO; CORRESPONDING FELLOW OF THE NEW YORK OBSTETRICAL SOCIETY.

A good deal has been written lately regarding the value of the microscope as an aid in the diagnosis of supposed ovarian tumors. Nearly all the evidence furnished has been against the value of the microscope, and especially against the asserted pathognomonic character of the so-called ovarian corpuscle of Drysdale. Some writers, while seeking to throw doubts on the specific character of this corpuscle, have gone too far and denied all value to microscopic observations in this connection.

It is rather the fashion at present for clinical observers and operators to belittle and run down the value of the microscope in the diagnosis of tumors. The reasons for this I have discussed in another place,1 and will not rehearse them here, only saying that it comes largely from ignorance as to the true place which the microscope should hold as an aid to diagnosis. If used in the proper way, and with the proper spirit, and with, of course, the necessary skill, it affords the intelligent interpreter much valuable information, and thus often enables him to get an idea as to the true nature of a case which, without it, would have remained an impenetrable mystery.

---

* Presented, with specimens, before the New York Obstetrical Society, May 15, 1883.
1 "Buffalo Medical and Surgical Journal," March, 1883.
We must not expect too much, but take the teachings of the microscope in conjunction with the clinical features of the case, supplementing one with the other and putting the whole together in one comprehensive picture. In this way we shall rarely be misled, one method correcting the possible errors of the other. As to the Drysdale corpuscle, I do not believe in its specific nature any more than I believe in the cancer cell. But this is very different from throwing over entirely the diagnostic value of the microscopic examination of doubtful abdominal tumors.

The case now to be detailed is a striking example of what aid may be obtained in this way. Without the microscope no certain diagnosis could have been made, except by resorting to an exploratory incision, the indications for which were hardly sufficiently strong to warrant it before the character of the contents of the tumors was ascertained.

CASE.—I was asked by Dr. Crawford, of Buffalo, to see Mrs. S., aged forty-nine, the mother of four children, the youngest being twenty-six years. The first and fourth deliveries were instrumental, and were followed by fever and great pain, and tenderness in the pelvic region. In 1887 she had a pelvic abscess, which broke into the rectum. Following this there was constant trouble with the bladder and rectum. In January, 1882, she had a severe chill, followed by fever, nausea, and vomiting, and pain and tenderness over the abdomen, worse in the pelvis. There was a burning pain in the bladder and urethra, with constant desire to empty the bowels and bladder. She grew constantly worse, was greatly depressed, and nearly helpless. The bladder could only be emptied in the knee-echest position, and copious eczems and prolonged efforts, lasting sometimes for hours, were necessary to empty the bowels. Rest and sleep were impossible except under the influence of powerful opiates. The abdomen also began to enlarge. I saw her in October, 1882. At that time she was a great sufferer, reduced in strength, emaciated, with nearly constant elevation of temperature (108° and more), and frequent attacks of vomiting.

An examination revealed the presence in the abdominal cavity of a large, nearly solid mass, which filled the cavity of the pelvis and reached to the umbilicus. A little to the right of the median line there seemed to be a groove dividing the tumor into two. A vaginal examination showed the uterus to be fixed in a mass of old inflammatory effusion, which made it impossible to feel the supra-vaginal portions, or to determine the relations of the tumor to the pelvic organs. Within the cervix and partly protruding from the external os there was a hard polyposus of the size of a hen's egg. The uterine sound could not be passed.

Dr. Crawford stated that the intracranial tumor had come down into the cervical canal during the year of his attendance, and that it had diminished in size during its descent. It had formerly produced severe menorrhagia, but of late this had greatly abated.

As the abdomen was too tender to allow of a proper examination, I determined to put her under the influence of an anesthetic, and remove the fibroid and make a thorough and careful investigation of the case.

This was accordingly done, the fibroid was easily twisted off, and the base cauterized. The uterine sound was then passed, and the uterus found to be pressed backward in the pelvis, to be only a little enlarged, and quite firmly fixed. On carefully palpating the abdomen, I found that the tumors seemed to be really two tumors. They were firm, but somewhat elastic, and I thought I could detect deep-seated fluctuation; but all who have tried know the extreme unreliability of this sign, even in the hands of experts. The tumors seemed to be firmly adherent in the pelvis, but what their points of attachment and origin were it was impossible to determine.

Here, then, was a case where the history and the results of palpation and percussion, the methods on which we chiefly rely in such cases, were unable to furnish sufficient data on which to base a diagnosis. The tumors might be fibroid. The fact that they were multiple, that a fibroid was known to have existed in the uterus, their attachment to the pelvis, and their firm consistency, all pointed in this direction.

The fluctuation, if there were any, might be due to a cyst formation in the tumor, a no uncommon event in the history of a fibroid.

On the other hand, they had grown somewhat rapidly, while the fibroid had not increased at all, but had rather diminished. The uterus was not much enlarged, and, moreover, double ovarian tumors, supposing them to be of this nature, were not so very uncommon. My opinion was strongly in favor of their uterine origin, but I did not feel satisfied. There seemed to be but two ways out of the difficulty— aspiration, with a microscopic examination of the matter which might be withdrawn, and an explorative incision. The former, as being much simpler, and, if done with proper precautions as to cleanliness, almost entirely harmless, was my choice. I therefore introduced a long, fine needle slowly into the left tumor, this seeming to be rather the softer. When the needle had reached the depth of about three inches, a thick, yellowish fluid, slightly stained with blood, began to pass slowly through the tube. About half a draught in all was obtained, and the needle withdrawn. Pending the result of an examination of this fluid, the patient was put on tonics, with the hope of benefiting her general health. Under the microscope, the fluid withdrawn by the aspirator showed a multitude of small cells which corresponded to all the tests for Drysdale's corpuscles. In size they were about the same as pus cells, though they were more variable, some being much larger, and the majority rather smaller. Besides these there were a few large, compound granular corpuscles and a very few cylindrical epithelial cells. The result of this examination showed to my satisfaction that the tumors were most certainly not fibroid in character. A fibroid might contain pus corpuscles, which I might possibly have mistaken for the ovarian corpuscle, but a fibroid or fibro-cyst could never contain cylindrical epithelial cells, so that, even throwing out the corpuscle in question, the microscopic evidence was strongly against a fibroid, and entirely in keeping with the ovarian theory of their origin. Not feeling perfect confidence in my own opinion, I sent some of the fluid to Dr. Drysdale, who was kind enough to examine it, and returned the following report:

"I have examined the specimen sent me, and think it is from an ovarian tumor."

Feeling now quite sure of my diagnosis, I determined to make an exploratory incision, and, if possible, to remove the tumors. The patient in the mean time had not improved at all. The morning of the day of the operation was spent in vomiting. Her temperature had shown nearly a constant elevation, with a rapid and feeble pulse. She could not rest or sleep, and was ready for anything which afforded a chance of relief, no matter at what risk. I operated November 7, 1882, at 2 o'clock A.M., assisted by Drs. Crawford, Mynter, and a number of other gentlemen. The patient was etherized, and an incision made in the linea alba about three inches in length. On introducing the hand, I found the tumors to be unsticked above the brim of the pelvis, except a little posteriorly and slightly to the omentum. They were both closely attached to the uterus, one on either side. At the brim they were held by thick, broad bands, which bound them firmly everywhere to the pelvis. They were also attached to each other, though the adhesions were not very

July 7, 1883.] MANN: REMOVAL OF TUMORS WITH THE UTERUS.
strong. The uterus was pushed backward. In the left tumor, which was the larger, there were several small cysts.

Thinking that the tumors could be removed, though the operation promised to be an exceptionally difficult one, and taking the woman's desperate condition into account, I determined on the radical operation. I first enlarged the abdominal incision to six inches, and then emptied the two larger cysts. The adhesions were broken through with the fingers as far as possible, and separated into bands, which were then tied with carbozilized silk and burned off with the thermo-cautery. It was very difficult to separate the adhesions and get them into shape for tying, and a great amount of force was necessary. My hand became so fatigued as to be nearly powerless, and I was obliged to call upon Dr. Mynter to work for a few minutes while I rested. The attachments of the right tumor to the uterus, to its fellow, and to the sides of the pelvis were easily torn through, and did not bleed to any extent. There was no distinct pedicle on the right, but on the left the pedicle was broad, thick, and short; it was divided by the thermo-cautery. As to its exact nature I was in doubt, but it proved to be the cervix uteri. When the tumors were both finally removed, the abdominal cavity was carefully cleaned and searched for bleeding points, but none were found; very little blood was lost. The wound was quickly closed by deep sutures of silver wire, and dressed with cotton wet in a solution of boroglyceride (1:20), with dry cotton outside, the whole held in place by a bandage, no adhesive strips being used. The operation was very long and severe, and the amount of shock exceptionally great. It was necessary to suspend the ether and give frequent hypodermics of brandy during the final steps, in order to get the patient off from the table alive. The latter part of the operation was therefore a good deal hurried.

At 6 o'clock p.m. she suffered great pain, with nausea and vomiting; pulse 130, and temperature 96°; extremities cold, but, under the free use of brandy and heat, she gradually rallied. During the night she urinated into a bed-pan, with great ease, for the first time in over a year. The urine was drawn by a catheter for a few days afterward, but this was soon given up, as she preferred the bed-pan. The first night she slept a short time under the influence of morphine, and in the morning had rallied and felt very comfortable.

On the evening of November 11th (5th day) the temperature for the first time went above 100°, reaching 101°, with a pulse of 98. The next day it rose to 101:3; pulse, 120; skin hot and dry, tongue dry, expression bad, and slightly delirious. At the same time a tender swelling developed over the left parotid region, and the outlook was very discouraging. On the following day the swelling had increased, but the temperature and pulse were lower. On the 15th (8th day) she was decidedly better, swelling decreased one third, pulse and temperature still somewhat higher in the evening. She improved steadily from this time. On the 19th she had a good deal of pain in the abdomen, and, on removing the dressing, a small abscess was found to be forming on the left side of the wound, evidently between the layers of the abdominal walls. Parotid swelling nearly gone. She continued comfortable, though with an evening temperature of 102° until the 22d, when fluctuation was apparent and the abscess was opened. There was considerable sloughing of the skin over the abscess and in its neighborhood, but, under a dressing of boroglyceride, the cavity healed rapidly by granulation. The patient has since then recovered a fair share of health, but is a good deal troubled by the irritable state of the bladder and by the pressure of the pelvic effusion on the rectum.

A curious fact is that, although both corpus uteri and ovaries are gone, there have been several uterine hemorrhages, twice so severe as to require a tampon. Each time they have followed straining at stool. They are growing less, and will, doubtless, soon cease. The pelvic roof is as hard as a board, and the presence or absence of the uterus could not be determined by palpation.

The formation of an abscess between the layers of the abdominal walls, probably within the sheath of the rectus muscle, with sloughing, may, perhaps, be accounted for by the injury done during the forcible breaking up of the adhesions and extraction of the tumors. Possibly the reduced condition of the patient had something to do with it. The antiseptic dressings slipped partly off on the second day, and were replaced without any disinfection, so that it can not be called a failure of antiseptic surgery.

One of the most interesting points in the case is the occurrence of the swelling of the parotid with perfect recovery. That it had its cause in septic processes can scarcely be doubted, the point of origin having been in the abscess. I made a very grave prognosis on its occurrence, having always looked upon it as a symptom of almost necessarily fatal import, and was proportionately gratified by its rapid subsidence. The believers in medication might attribute the rapid recovery to sulphide of calcium (gr. 1/4, q. h.), given with the idea of preventing suppuration.

About the same time a case occurred in the Buffalo General Hospital of a lad with a pistol-ball in his abdomen, where the same symptoms developed, and with the same result,—i.e., perfect and rapid recovery. The operation was done under a spray of boroglyceride, 1:20. I have used it in four ovariotomies since, and in each case there has been a prompt aseptic convalescence. My experience with carbolic spray in abdominal section has made me afraid of it, but in boroglyceride we have a substance which is quite as good a preventive of putrefaction, while it possesses none of the poisonous, irritating, and buming properties of the acid. Although recent experiments tend to show that a spray does not destroy aërial germs, still it certainly keeps the tissues which are exposed to the air, and so to it, moistened with an antiseptic solution, and serves as a sort of irrigation, the only irritation which is generally allowable in the abdominal cavity. It is almost needless to say that hands, instruments, and sponges were thoroughly cleaned.

A careful examination of the specimen will show that with the left and larger tumor I removed the whole of the corpus uteri as far as the internal os. The removal of this organ was unpremeditated, but an examination of the specimen will show that it would have been almost impossible to separate the tumor from it. The tumor evidently grew between the folds of the broad ligament, pushing this upward and outward, and this was the cause of the exceedingly firm adhesions which I found gluing the tumor to the pelvic brim. Enucleation of the tumors from between these folds would have been impossible, and the only way was to break them up into bands and tie these one by one. Below these bands, which made a sort of a diaphragm across the roof of the pelvis, the adhesions were soft, and easily separated.

The stump of the uteri should, according to expectation, have given a great deal of trouble from hemorrhage,
but it did not bleed at all. May this not be taken as a point in treating the pedicle in hysterectomy! If the cautery will stop the hemorrhage, why is it not better, after tying the uterine arteries separately, to treat it in this way than by the extra-peritoneal method with the clamp? We commonly divide the cervix by the cautery in amputation for cancer, and, although we sometimes have trouble from secondary hemorrhage, still this is rare, and would not be so likely in the case of a stump left in the peritoneal cavity as in one left to slough and ulcerate in the vagina.

I have not examined the specimens microscopically, but the tumor seems to be an ordinary adeno-cystoma with excess of adenoid formation.

Buffalo, May 3, 1883.

THE AMERICAN MEDICAL ASSOCIATION
AND THE MEDICAL CORPS OF THE
NAVY:

AN OPEN LETTER TO THE SURGEON-GENERAL OF THE NAVY.

By ALBERT L. GIHON, M. D.,
MEDICAL DIRECTOR, U. S. NAVY.

PHILIP S. WALES, Esq., M. D., Surgeon-General, U. S. Navy, Chief of Bureau of Medicine and Surgery, Navy Department, Washington, D. C.

Sir: My official responsibility to yourself, by whom I was detailed to represent the Medical Corps of the Navy at the recent meeting of the American Medical Association, as well as a sense of justice to my colleagues in the corps in whose name I acted, renders it proper that I should formally explain the circumstances attending the presentation of my paper, entitled "Medical Education the Fundamental Fact in Medical Ethics," before the Section in State Medicine. Before going to Cleveland I had submitted this paper to yourself as the official head of the corps, that I might be assured I correctly represented its views, in which assurance I was further strengthened by those of our professional associates whom I had the opportunity of consulting.

Subsequent to my selection, by the Committee on Nominations, as one of the vice-presidents of the association, I was advised that an incomplete newspaper report of this paper had been made the basis of a charge that I was hostile to the code of the association, to which, with others, I had subscribed on registering as a delegate; and I requested my friend, Dr. McMurtrie, of Louisville, Ky., to introduce the subject in the committee, that opportunity might be offered for such objection, with the discovery that it was based on my assumed advocacy of a faction in the profession as against another faction, a position I had carefully endeavored to avoid, having presented the paper in the interest of peace and harmony, and with the very object of establishing that the common ground on which all educated physicians should stand made such dissension unnecessary; and I, consequently, did not hesitate to satisfy the committee, by a pencil memorandum hastily written on the moment, that "I adhered to the code of the association, and opposed any violation of it." This memorandum

signedly came before the association in an informal manner, and was reported in the press, with various additions, amplifications, and exaggerations, to the effect that I "stood by the old code first, last, and all the time," I was a "firm believer in the code in all its parts," that I had "backed down," "recanted my heretical opinions," etc.; but my official duties as Member of the Board of Inspection of the Navy compelled me to leave Cleveland without giving the matter other notice. I took the opportunity, however, when transmitting the manuscript of my paper through the secretary of the Section in State Medicine for publication in the journal of the association, to append the following detailed statement of my understanding of the true intent of the code. I have since submitted this statement to some thirty or more members of our corps, and am assured, without exception, that it correctly represents their individual views:

It is almost an insult to the intelligence of the readers of the journal of the association to explain that this paper is not intended as a sectarian attack upon the organic law of the American Medical Association; but, as this interpretation has actually been given it by over-sensitive partisans, I deem it proper to reaffirm my loyalty to the code to which I have subscribed, without, however, surrendering the right which, in common with every intelligent man, I claim to criticise what I may think objectionable, and to call attention to the inconsistencies of its avowed adherents, who, attempting to observe its letter, ignore its spirit. I fail to see why honest advocates of its principles should be placed in an attitude of "rebellion" for merely defining these principles by the more liberal light of this day. The code properly interdicts any admission of the orthodoxy of the professors of exclusive dogmas, whether of homoeopathy, allopathy, hydropathy, or the like, but it nowhere prohibits the intelligent physician giving his advice to any one whomsoever who may seek it, especially when emergencies and dictates of humanity demand. No one can more energetically disavow than myself the impossible co-treatment of any case of disease by an educated physician on the one hand, and a charlatan, empiric, quack, or ignoramus, however "regular," on the other; but it is quite another matter when one's own opinion is solicited in behalf of suffering humanity. I have yet to hear of any of our profession soliciting an opinion from any of these, and without such an interchange of views there can scarcely be considered any consultation, in the sense of the clinical co-operation properly denouced by the code. Any narrower assumption will, as I have endeavored to show in this paper, necessitate the ostracism of those of our distinguished colleagues who have associated as fellow medical members with homoeopaths and eclectic in the professional work of the National Board of Health, State Board of Health, Board of Medical Examiners, etc., and I feel assured that the overwhelming sentiment of the American Medical Association will be in favor of the liberal interpretation I have here given the code, with the previous knowledge and approval of the Surgeon-General of the navy.

Further comment is hardly necessary in advance of the publication of the paper, which I fear will scarcely be found to deserve the prominence given. It will have failed in its purpose if it does not convince its readers that the ethical platform reared upon a foundation of thorough medical education is the one, and the only one, on which every intelligent member of the profession can rightly stand. The attempted division of the profession into rival camps of old
Colers and new colers is deplorable and entirely unnecessary, and I protest, as an individual, and in the name of the corps I represent, whose professional eustachian is without blot or bar, against being made a party to it. A cast-iron code of any sort is as impossible as a rule of conduct as would be the attempt to define a Christian by a rigid declaration of faith to which all men must subscribe without question, or to devise a set of pocket rules for genteel behavior as an inflexible guide for a well-bred gentleman. When the profession shall have rid itself of ignorant, illiterate, and incompetent pretenders, there will be no question as to what is right and what is wrong; but this is not to be accomplished by driving out of the association those who, having an equal right there, choose to interpret their creed for themselves, and who find the existing code wide enough and broad enough to permit that freedom of action to which every honorable and intelligent member of society, whatever his vocation, has an inherent and inalienable right. When this is demonstrated to be impracticable (and this has not yet been done, and can not be done without full, fair, and unrestrained discussion), the remedy will be found not in devising other codes to be new bones of contention, but in doing away altogether with what, having been originally merely a liberal declaration of principles, has been sought to be converted into a narrow party platform.

I have the honor to be, very respectfully,

Your obedient servant,

Albert L. Gihon,
Medical Director, U. S. Navy.

THE ORIGIN OF
CREPITANT AND SUB-CREPITANT RALES.

By D. M. CAMMANN, M. D.,
Late Attending Physician to the New York Dispensary, Class of Diseases of the Heart and Lungs.

It may, I think, be proved, by logical deductions from physiological facts, that crepitant and subcrepitant râles are not produced in the smaller bronchi and air-vesicles; and that they, as well as coarse or "mucous" râles, have their origin within the pleura, has been made evident by the records of many post-mortem examinations.

Two views are held by authors who assert that the crepitant râle has its origin within the air-cells. One is that the râle is produced by the agitation of fluid within the air-cells; the other, that as the air-vesicles are diluted in inspiration their walls are suddenly separated from their fluid contents to permit the passage of the current of air, and that these râles may sometimes arise from the sudden separation of the cohering walls of the alveoli quite independently of the existence of any trace of exudation.

The subcrepitant râle is supposed to have its origin in the smaller bronchi, and to be caused by the bursting of bubbles of air.

If these views are true, the respiration must have considerable force in the air-vesicles and smaller bronchi, or at least there must be a current of air passing in and out with each respiration. But physiology teaches that this does not occur. The change that takes place in the air in the air-cells and smaller bronchi is not by currents of foul air passing out in expiration and currents of fresh air passing in with inspiration, but the change is governed by the well-known law of the diffusion of gases. "This diffusion is constantly going on, so that the air in the pulmonary vessels, where the interchange of gases with the blood takes place, maintains a pretty uniform composition." *

"By diffusion," says Foster, † "the new or tidal air gives up its oxygen to and takes carbonic acid from the old or stationary air. In this way, by the ebb and flow of the tidal air, and by diffusion between it and the stationary air, the air in the lungs is being constantly renewed." "Now, it is obvious if no provision existed for mingling the air inspired with the air already occupying the lungs, the former would penetrate no farther than the larger air passages. The change [in the air in the lungs] must be attributed to the 'mutual diffusion' of gases, these tending to interpenetrate one another, when of different densities or of different temperatures." ‡

That such is the case is evident from the fact that only about one tenth of the air in the lungs is changed in each respiration. When one lung is crippled by disease the other lung does extra work, as is evidenced by harsh respiratory murmur over the unaffected side, and the diseased lung receives less air than usual at each respiration. And yet it is over such a lung, receiving a small amount of air and in which there can not be currents in the smaller bronchi and air-vesicles, that crepitant and subcrepitant râles are often heard. That râles may arise from the sudden separation of the cohering walls of the air-cells is contrary to the teachings of physiology. The air-cells do not collapse in expiration; nine tenths of the air in the lungs at the end of inspiration remains at the end of expiration. That râles may arise in air-cells partially filled with exudation by the separation of their adhering sides seems more probable. But it must be remembered that little air enters the parts of the lung where the exudation has taken place; there can be little or no current; the lung is crippled, and expansion and contraction take place to a very limited extent. Has any satisfactory proof ever been adduced to show that crepitant râles are naturally produced under this condition? I think not. On the other hand, that crepitant and subcrepitant râles are produced within the pleura has strong evidence in its support.

Cases are on record * in which râles were heard a short time before death, and, on post-mortem examination, pleuritic exudation was found in the same situation while the lung beneath in some cases was not diseased; in others there was consolidation, so that no air could have entered the lung in the neighborhood where the râles were heard. To test the correctness of these views, advantage was taken of the large

ON ONE OF THE DANGERS THAT MAY ARISE AFTER TRACHEOTOMY.]

BY EDWARD L. PARTRIDGE, M. D.,
PROFESSOR OF OBSTETRICS IN THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.

The specimen here shown is the larynx of a child, two years of age, upon whom I performed tracheotomy on the 8th of March, at the Nursery and Child's Hospital, for the relief of symptoms due to diphtheria.

When the child was taken sick the diphtheritic membrane was to be seen on both tonsils and on the uvula. The constitutional symptoms were not very severe, the temperature ranging below 103° F., and the pulse being of fair strength and easily counted, although soon afterward it reached 150. At the end of two days there were indications that the larynx had been invaded; the respiration was somewhat quickened and difficult, the dyspnea affecting both inspiration and expiration, and there was a lack of the physiological period of rest between these two acts.

The child's condition grew worse during the forty-eight hours following the invasion of the larynx; cyanosis was becoming manifest, and it was the opinion of those of my colleagues who saw the patient with me that tracheotomy should be performed at once. The operation was done with comparative ease; the large veins were avoided, so that very little hemorrhage took place, and a tracheotomy tube was introduced. The tube was somewhat faulty in construction, but it was the only one at hand. It was faulty because when in its place in the trachea the situation of the fenestra in the outer tube, which opens upward toward the larynx, was so far forward as to be entirely anterior to the lumen of the trachea. Laryngeal respiration could not take place, therefore, without removal of the tube.

The patient's condition improved immediately; the pulse fell to between 120 and 130, the temperature sunk to 102°, and respiration through the tube was quite free. Very little discharge of mucus took place through the tube for the first twenty-four hours, and there seemed good ground for hope that recovery would ensue. Thirty hours after the operation, however, the house physician fancied that the child was not breathing quite so freely as it had been doing, and sent for me. I found the patient doing comparatively well, but, thinking there might be some advantage in another and more suitable form of tube, I proceeded to make the exchange. The child continued to breathe freely after the removal of both the inner and the outer tube, but, when the new one was introduced instead, it ceased to breathe, and immediately began to show signs of impending suffocation. A probe was hastily passed through the tube, and it entered without difficulty, but the breathing was not improved. The first tube was then replaced, but without benefit; it was withdrawn and a catheter was inserted. Air passed through all these tubes, but so imperfectly that the child's face began to grow livid, and in less than five minutes death took place.

But one explanation of the occurrence suggests itself to me; that on the introduction of the second tube a portion of the diphtheritic membrane was detached, and almost completely blocked the lumen of the trachea just below the tube. At the post-mortem examination the membrane was found to extend down the whole length of the trachea, and a short distance into the bronchi.

The case seems to illustrate the danger of the early removal or exchange of the tube. I am aware, however, that there is excellent authority in favor of the practice. Indeed, Bonnet believes that the most important point in the after-treatment consists in the daily removal of both tubes after the second day; first, in order to ascertain whether the patient can or cannot breathe through the larynx, and, second, to guard against the overgrowth of granulations at the upper end of the wound.

A METHOD OF CLEANING CATHETERS.—A correspondent of the "Lancet," says: "Take a cork of a more conical form than that commonly used, with a hole made through it longitudinally; pass the catheter through the hole, and fix the cork into the tap of an ordinary water-pipe (hot-water one preferable), and turn on the water. By so doing, the force of the water is greatly increased, and the catheter properly cleaned."
By Dr. Adam Politzer, Imperial-Royal Professor of Aural Therapeutics at the University of Vienna, etc. Translated and edited by James Patterson Cassella, M. D., M. R. C. S. Eng., Aural Surgeon to, and Lecturer on Aural Surgery at, the Glasgow Hospital and Dispensary for Diseases of the Ear. With 257 original illustrations. Philadelphia: Henry C. Lea's Son & Co., 1883. Pp. xii-800.

The English translation of the great work of Politzer, in two volumes, comes to us in one large volume, complete in itself, and is the fullest and most exhaustive treatise upon the whole science of otology that has ever been published in any language. The first volume of the German edition was published at Stuttgart in 1878, and treated of the anatomy and physiology of the external and middle ear, the diseases of the naso-pharynx and membrana tympani, and the acute inflammatory and eardrums affections of the middle ear. The second volume, published in 1882, considered the adhesive affections and purulent inflammations of the middle ear; diseases of the mastoid process and the external ear, and the relations between ear disease and life insurance; the anatomy, physiology, and diseases of the internal ear, including the labyrinth and the auditory nerve, injuries of the internal ear, cerebral disturbances of hearing, malformations of the ear, and deaf-mutism. The English translator has followed the same order in his translation, which, as will be seen, differs from that ordinarily employed in text-books. In considering the work as a whole, the first thing that strikes the reader is the large number of anatomical and pathologico-anatomical observations and illustrations, which place this work so far above any similar work on the subject hitherto offered to the profession.

It is well known that Professor Politzer has for many years been among the most earnest workers and closest observers in the field of otology, and his contributions have always been marked by the most thorough and meritorious workmanship. The English translation is most admirable for the painstaking care manifested in combining literal exactness with clearness of expression. Of course, to the busy otologist and general practitioner the chief interest centers in the pathology and treatment of the diseases of the ear, and perhaps especially of those of the middle ear. That very large class of cases which come under the head of adhesive processes in the middle ear receives special attention, not only because they are so very frequent, but also because of the greater frequency of labyrinthine complications. Politzer thinks in these cases the affection of the middle ear and the labyrinth is produced simultaneously by similar trophic disturbances. In the treatment of this class of cases he has introduced a novel operation, that of division of the anterior malleolar ligament for retraction of the handle of the malleus. His opinion as to the real value of tenotomy of the tensor tympani muscle is somewhat unfavorable.

We do not think the author is justified in distinguishing so positively acute purulent inflammation of the middle ear without perforation of the membrana tympani, from acute otitis media. In many, perhaps the majority of cases, they differ merely in the occasional perforation of the drum-membrane. The recommendation of Politzer in obstinate cases of acute suppurative, to inject hot water into the middle ear through the catheter, seems to be well worth extensive trial, as a means of relieving severe pain, if for no other reason.

The chapters upon chronic suppurative processes in the middle ear are very complete and exhaustive, and are filled with valuable pathological and pathologico-anatomical observations, especially with reference to the minute deep changes in the drum cavity and mastoid cells.

When we come to the chapters on the diseases of the labyrinth and auditory nerve, we find a much better and fuller description of this class of cases than exists in any other work; but Politzer, like every other author, has been hampered by the infamy of our knowledge upon this subject. This is mainly owing to the great lack of numerous and accurate post-mortem examinations of the ear in patients who have died from these diseases or from cerebral complications. Still, Politzer has given the best description of Ménière's disease, both in its simple and in its apoplectic forms, that we possess. The section upon the Diagnosis of the Diseases of the Auditory Nerve is admirably clear and well expressed. The author devotes a special section to panotitis, or that form of disease in which the middle ear and labyrinth are attacked by the inflammation either simultaneously, or the one very quickly after the other. This occurs chiefly in children in the course of scarlatinal diphtheris farinum, or as an idiopathic affection. Another interesting section is the one which describes the New Formations in the Internal Ear.

Another section that is to be especially commended to the reader is the one upon Cerebral Disturbances of Hearing, because of the obscurity of knowledge which has hitherto been so general.

There is a final section upon Hearing Instruments for the Deaf, and in the appendix is a collection of therapeutic formulæ occurring throughout the book.

Finally, we would say that the work is a monument of patient labor, quick observation, and keen insight, the whole illumined by the enthusiastic spirit of its brilliant author.

That which includes the subject of this work there is no branch of medicine demanding more pressingly from exponents and investigators the severest methods of science. Comprehending for its immediate and contingent subject-matter phenomena exceeding in variety and intricacy all others with which the physician has to deal, there are, above all things, required an unusual clearness of thought, the application of unimpeachable logic, and the most careful arrangement of matter and order of argumentation.

In these regards there are numerous shortcomings in the work before us, and on the score of them we must find fault with what in some respects is a commendable book. Under the heading “The Vice Aspect” we learn that nerve centers may be disturbed by a latent functional impulse. Again, at page 164, under “The Psychological Aspect of Inebriety,” we find the following: “But let such a sluggishness be temporarily aroused, reawakened even by an artificial stimulant, and, whether it be an arousal of psychical energy which is transmitted to the consciousness or representation, or by a combination of other forces or qualities, the fact is still apparent, and is vivid with instruction.” “Arousement (l) of a sluggishness” is singularly out of place in a chapter engaged with the psychological aspect of any subject. The meaning intended to be conveyed by these and other improper verbal collocations and unskilfully constructed sentences is not “apparent,” and they are not “vivid with instruction.”

There are contained, nevertheless, some able, and even eloquently, written passages, and we especially indorse the spirit of reasoned philanthropy with which the subject generally is treated.

The following quotations are taken from a summary of the conclusions to which the author has been led:

Book Notices.

[From N. Y. Med. Jour.]
"Some persons are born with an alcoholic diathesis—that is to say, with an appetite for alcoholic beverages and a tendency to intoxication."

"It is the internal craving for alcoholic liquors and for their intoxicating effect that constitutes the disease, and not the fact of drunkenness."

"The most successful treatment is that which combines with wholesome restraint psychological and hygienic methods, such as are successfully employed in hospitals for inebriates."

Dr. Stearns's large practical experience among the insane admirably fits him for the task he has undertaken, which is one that implies the consideration of insanity in its aetiological relations; but in some respects the book resembles Tuke's excellent little work published several years ago.

After the preliminary discussion of the prevalence and increase of insanity among savage and civilized peoples, he proceeds to the consideration of the influence of education, heredity, consanguineous marriages, alcoholism, poverty, religion, and insufficient sleep. Dr. Stearns's suggestions are practical, but commonplace, and what he says has been gone over again and again. His words have, however, the merit of directness and truth, and his conclusions are based upon much study of mental disease and association with the insane. The book is one for the public rather than the medical profession, and must have its good influence. The evils of over-study and injudicious teaching are pointed out, and the author strongly urges the advisability of not treating all children alike in the matter of brain work. In regard to heredity, useful hints are given to parents who have "queer" children. Dr. Stearns points out the mental peculiarities that some children present, and which are, after all, forerunners of what may be grave psychological defects in adult life. He thinks that special care and training should be provided for the "precocious," the "passionate" or "cruel," the "timid," the "willful," and the "lonely" child. We would suggest that "the eccentric" and "the stupid" should be added to the list. Much useful personal research has been made by Dr. Stearns, and we find upon every page something of interest and instruction.

Mental Pathology and Therapeutics. By W. Griesinger, M. D., Professor of Clinical Medicine and of Mental Science in the University of Berlin, etc. Translated from the German (second edition) by C. Lockhart Robertson, M. D. Cantab., and James Rutherford, M. D. Edin. New York: William Wood & Co., 1882. [Price, $1.50.]

The original edition of this work was placed before the medical profession in the year 1847. Sixteen years later a second edition was issued, and this was translated from the German and published as one of the volumes of the New Sydenham Society's series in 1867. The volume before us is a reprint of that last mentioned, which is thus brought to notice after a slumber of sixteen years, and without alteration, note, or comment.

Antiquated, therefore, as the work may seem to be in these days, when a publication relating to any scientific subject is often old in a year, no one who desires an acquaintance with mental pathology and therapeutics can afford to neglect Griesinger's book. The views of its author are so decided, and when he wrote were so far in advance of his time, that they mark an era in the progress of psychological medicine. The author was one of the advance guard who, while they live, are the subjects of as much persecution as the spirit of the age allows, but who are pretty sure to get their just measure of distinction after their death. Even at the present day no one can pretend to a good education in alienistic science who is ignorant of the contents of Griesinger's "Mental Pathology and Therapeutics," and perhaps, all things considered, it is as well that it has been republished exactly as its author left it.

BOOKS AND PAMPHLETS RECEIVED.

Catalogue of the Albany Medical College, Medical Department of Union University, 52d Session, 1882-83. And Announcement for Session 1883-84.

Second Annual Announcement of the Iowa College of Physicians and Surgeons at Des Moines, 1882-83.

Announcement of the Twenty-third Annual Course of Instruction at the Miami Medical College of Cincinnati, with a List of Matriculants and Graduates of 1882.

Suture de la vessie pour une très grande plaie intra- et extra-péritonéale; réparation en deux actes opératoires d'oignons; guérison. Par le Dr. S. Pozzi, professeur agrégé, etc. Paris, 1883. [Reprint from the "Annales des maladies des organes génito-urinaires."]

(University of the State of New York), 1883-'84. Prospectus of the College of Pharmacy of the City of New York.

Ninth Annual Announcement of Columbus Medical College, Columbus, Ohio. Session of 1883-'84.

Twelfth Annual Announcement of the College of Medicine of Syracuse University. 1883-'84.
THE DANGER OF A VISITATION OF CHOLERA.

European advices in regard to the prevalence of cholera in certain districts of Egypt, a summary of which will be found in another article, are apparently tinged with a spirit of panic, and in some respects amount to little more than a string of rumors. Nevertheless, the general tenor of the facts on which they seem to be founded is grave enough to raise apprehensions that the pestilence may find its way to this country. Some of the newspapers are playing the optimist, however, and regale their readers with suggestions to the general effect that cholera is now much more manageable than it was a number of years ago.

While it is undoubtedly true that in recent years we have made decided gains in our knowledge of the best means to follow for the prevention of the disease, and while there is abundant evidence that the community is year by year attaching more importance to sanitary measures in general, and in particular to those adopted as safeguards against great epidemics, it is to be feared that, practically, this is all that can be said. We doubt very much if cholera, once it had gained a foothold on our shores, would show itself remarkably more tractable than in bygone times. We are not aware that the treatment of the disease furnishes very flattering results even at the present time. At all events, those who remember even the mild epidemic of the year 1866 can scarcely look complacently upon the risk of even a little cholera in New York. It seems to us the part of wisdom, therefore, to look upon the danger as real, and to leave no stone unturned to ward it off.

On the other hand, the probability that the disease will gain a lodgment in the United States this summer is exceedingly small. In the first place, it has not yet crept along the Mediterranean to any of the ports with which our communication is at all considerable; and it has shown itself late, even for a country so far east as Egypt. Our direct commerce with the Egyptian ports is trudging, and it can not be said to be large with those countries in Europe to which the infection would naturally be first conveyed.

While, ordinarily, the lethargy of the Ottoman authorities in regard to sanitary measures, as well as in respect to all the rest of the machinery of civilization, might well give rise to the fear of a general infection of Europe by way of Turkey, there is a special element at work at the present time to offset that danger. We refer to the exceptional sense of responsibility which the British government must feel, apart from solicitude for the protection of its own people, from the fact of its having undertaken so leading a part in Egyptian affairs, including the matter of sanitation. It seems to us, therefore, that the European powers that are said to have appealed to Great Britain to exercise the utmost vigilance in preventing the extension of the disease are justified, and that the world is justified, in looking to the British nation for a promptness and a thoroughness of action that should go far toward neutralizing the natural laxity of the Porte.

All these powers will, of course, add their own watchfulness to what they expect of England, and, as a consequence, the progress of cholera through Europe will be slow, even if it takes place at all. Such being the case, it is scarcely possible for it to reach the ports with which our commerce is chiefly concerned until so late a period in the summer that the danger of its crossing the Atlantic will have been effectually barred by the limitation of season. As a general rule, too, our cholera epidemics have begun in years following a European prevalence, so that it is rather for next year than this that the contingency of an inroad of cholera into Europe should excite uneasiness in America.

Still, our quarantine service can not be too stringently carried out. Considering the leading part played by New York as a port of entry, and especially as a landing-place for immigrants, the attention of the country will be turned mainly upon the health officer of this port as charged with the duty upon the faithful and enlightened performance of which the safety of our people depends. While it can not be denied that the medical profession would feel a greater sense of security if his predecesor were still at the helm, it is to be said in behalf of our present health officer that he has made a favorable negative record during the period of his incumbency. To be sure, he has not yet been tried under any great danger, but the present demand comes upon him not as upon one altogether unused to the techniques of the office, so to speak; he has had ample time to familiarize himself with the routine of commercial sanitation, and he will be dull indeed if he overlooks the strict accounting to which the people will hold him in the event of any disaster occurring as a consequence of the inadequate performance of his functions. With the danger of cholera visiting us from the East, and of yellow fever drifting up the coast from the West Indies or from the Gulf, any remissness on the part of the health officer of New York would be nothing less than criminal. There is every reason to believe that nothing of the sort will take place, but that that officer will be found true to the interests of the State and of the nation.

A VICE-PRESIDENT OF THE AMERICAN MEDICAL ASSOCIATION ON THE QUESTION OF ETHICS.

Whatever honor may attach to the position of a vice-president of the American Medical Association, there are few men of any account in the profession, we fancy, who would forswear themselves for the sake of attaining to it; least of all should we look for men of such pusillanimity in the medical corps of the navy—a corps that has an unbroken record of honor. It was with the utmost incredulity, therefore, that we read the newspaper accounts of Dr. Gibon's having "backed down," and having uttered such drivel as that he "stood by the old code.
first, last, and all the time," and so on. That our trust in the common sense of the medical corps of the navy was not unfounded, will be evident to all who will take the trouble to read Dr. Gilson's communication, which we publish elsewhere in this issue.

It seems that, in order to correct a misapprehension on the part of the Judicial Council, he simply made a written statement that he "adhered to the code of the association, and opposed any violation of it." It is very much to the credit of the Judicial Council that they quietly accepted this statement (which, by the way, might be made in good faith by many an opponent of the code), without censuring Dr. Gilson further, or insisting upon any more explicit presentment of his views. They had, indeed, no moral right to meddle with the matter at all, so long as Dr. Gilson was not specifically charged with having violated the code. Between the violation of a law, that is to say, the commission of an act forbidden by it, and the avowal of a doubt as to the wisdom of that law, there is the greatest possible difference. The one is an offense justly punishable by the law-making power; the other is but the exercise of that liberty of opinion that is the innate right of every man, woman, and child in the country.

Dr. Gilson's paper is on record, and can not be blotted out. That he has no desire to undo its effect, and that the corps he represented at the meeting does not cherish any such wish, is abundantly evident from the communication sent us for publication, including as it does the supplementary note sent by the author to the official journal of the American Medical Association. Even if the address itself had never seen the light, Dr. Gilson's letter to Surgeon-General Wales would amply suffice to place him and his colleagues before the profession in an independent attitude. How many of them in their hearts favor the continuance of the old code as it now stands, how many prefer the code of the Medical Society of the State of New York, and how many think it would be best to have no code at all, we have no means of knowing; the point is, that, whatever their views on the matter, they are resolved not to be cuffed into unthinking adoration of the policy that treats men as enemies simply because they dissent from the dominant sentiment in the association.

"I fail to see," says Dr. Gilson, "why honest advocates of its principles should be placed in an attitude of 'rebellion' for merely defining these principles by the more liberal light of this day." If the association as a whole had chosen to take this reasonable view, the breach that now exists among us would never have been brought about.

AN ALLEGED CASE OF CRIMINAL ABORTION.

It is not a common thing for a physician in good standing to be charged with criminal abortion. That fact, however, does not warrant the conclusion that abortionists are not to be found in the regular ranks, however gratifying it would be to be able to draw such an inference, for every practitioner of much experience knows that numbers of women either are unnecessarily mendacious, or else, as they profess, really find so difficulty in getting "assistance" of a peculiar sort from one physician or another. This state of things can not be gainsaid; we can only deplore it. Moreover, there are men against whose character the world knows nothing, and yet in regard to whom some of their fellow-practitioners feel morally certain that they are delinquent, and debased by having followed the nefarious practice in question—only they can not prove it. No doubt many of these men are suspected unjustly, and, indeed, we believe that those who are really guilty are very few in number. As a matter of fact, it was only last week that this journal claimed credit for the profession on the score of the lofty stand it had never failed to take as a body in this matter; and we now recede not at all from the position we then took, but rather renew our expressions, for it is beyond question that sinners of this particular sort are rare, and only serve as the exception that proves the rule. In the interest of truth, however, their existence must not be ignored.

We bring these considerations forward at the outset for the purpose of showing that we are not disposed to attach too much importance to the presumption of innocence in what we shall say in behalf of a New York physician who is now held on a charge of criminal abortion. The circumstances of the case are these: Dr. David F. Austin, a practitioner whose career has been honorable, so far as we know—certainly one against whom no serious accusation has been brought—is declared to have caused a woman's death by an operative procedure undertaken with the design of causing an abortion. It appears that the woman had visited him several times, and that on these different occasions she had been subjected to what she called operations. Shortly after her last interview with the doctor (excluding that in which he was brought before her for identification) she became seriously ill, and the physicians who were called to attend her broached the suspicion that she was suffering from the effects of a criminal interference with gestation. Under some pressure, she seems to have virtually confessed that such was the case, and to have stated that Dr. Austin had "operated" on her. Being confronted with the doctor, she declared him to be the person she meant, and soon afterward died. A post-mortem examination was made, and those who conducted it declare that the woman's death was due to peritonitis induced by an artificial abortion. A coroner's jury found a verdict to this effect, and Dr. Austin is now on bail.

So far as it appears, this constitutes the evidence against Dr. Austin. As regards the autopsy, perhaps, the material facts concerning the cause of death were established by it, but we submit that it should not readily be taken to show a criminal intent, and, certainly, very little importance should be attached to the testimony of a man who swears, as one of the medical witnesses did in this case, that the woman could not have had a polypus removed last November, as asserted by Dr. Austin, because no scar was found at the autopsy. The abortion may, for all the examination is likely to have revealed, have been the result either of design, of carelessness, of unskilfulness, or of mere "misadventure." The ugly feature in the case, however, is the woman's ante-mortem statement. A woman on her
deathbed does not lightly accuse a man of having performed a criminal act. Still, the particular woman here alluded to may have meant only to convey the idea that the doctor's "operation" was, in her opinion, the cause of the trouble that was bringing her to the grave, without at all meaning to imply that the induction of abortion was the purpose he had in view. The report of the deathbed scene that comes to us will bear this interpretation, although its most obvious intent, it must be confessed, is to incriminate the doctor.

Speaking from what has thus far transpired, the doctor's defense rests on his own statement that his treatment of the woman was legitimate, i.e., for the relief of disease, and that the abortion (if there was an abortion) and the consequent inflammatory trouble were what might happen to any woman undergoing gynecological treatment, provided she chanced to be pregnant without the physician being aware of the fact.

If Dr. Austin is innocent, this is almost the only defense that will serve him, and it is in no wise irrational or strained, for many a gynecologist sooner or later produces abortion unwittingly, although, he may be thankful, it does not usually end in death. Moreover, Dr. Austin's statement is materially strengthened by the husband's admission before the coroner's jury that several months ago he sent his wife to Dr. Austin for treatment. As the case stands, it would be improper to express an opinion as to the guilt or innocence of the accused, even if it were possible to form a definite idea. While the interests of humanity and those of the profession call for adequate punishment in case his guilt should be proved, for the credit of the profession we cling to the hope that his innocence will be established.

MINOR PARAGRAPHS.

THE MASSACHUSETTS STATE BOARD OF HEALTH, LUNACY, AND CHARITY.

The nomination of Dr. B. A. Sawyer, of Duxbury, to a seat in the board is looked upon by some of the profession in Massachusetts as designed to introduce an element of discord, and make the old members of the board uncomfortable, owing to the fact that a lawsuit is now pending between the board and Dr. Sawyer in regard to an alleged nuisance in Duxbury. The Executive Council, it has therefore been suggested, ought not to confirm the nomination. Adverse action on the part of the Executive Council has been rendered unnecessary, however, by the withdrawal of the appointment.

COUNTER PRESCRIBING.

An apothecary named Leman, doing business at No. 2083 Second Avenue, is under arrest, charged with having caused the death of a Mr. Vollmer by opium poisoning. It is alleged that Mrs. Vollmer went to Leman's shop and asked to be directed to "some good German physician," whereupon Leman persuaded her to let him prescribe for her husband. The next day Vollmer died, and two physicians decided that the death was from poisoning with opium. It is understood that Leman does not deny the charge that he prescribed for the man, but maintains that his prescription was harmless. One of the physicians in attendance is reported to have said, however, that this was not the first case he had known of in which Leman's prescribing had been followed by fatal results.

ARMY AND NAVY SURGEONS AND THE MEDICAL SOCIETIES.

It is always a matter of gratification when a medical officer of the army or navy takes part in the proceedings of a local society, and we are persuaded that gentlemen in the service have it in their power to contribute notably to the interest of such meetings. We are pleased to learn, therefore, that Assistant Surgeon J. H. Bryan, of the navy, lately reported two cases at a meeting of the Medical Society of the County of Kings.

FATAL EFFECTS FROM THE BEE'S STING.

Elsewhere in this number of the journal we print an extract from the "Lancet" going to show that the sting of the bee occasionally proves fatal. An additional instance, if we may credit a press dispatch, occurred last week in the town of Milan, in Tennessee. The report is, that a woman was stung on the nose, and died in a few minutes. If it should really prove that in a number of cases death may fairly be imputed to the sting of the bee, the matter will be well worth investigating. Ordinarily, as is well known, only a local irritation is produced. If we concede that the mosquito can implant the Filaria su- quinis hominis in a man's blood, it seems not unreasonable to conjecture that the bite or sting of various animals not usually venomous may be made so on occasions of their having fed upon some septic or noxious substance. It is highly desirable that well-observed cases of this sort should be put on record.

A CASE OF PORRO'S OPERATION IN PHILADELPHIA.

On Friday of last week Dr. W. H. Parish performed Cas- rean hysterectomy at the Almshouse Hospital in Philadelphia, the patient being a dwarf. The woman survived until Monday, and at last accounts the child, which weighed six pounds, was doing well. The case seems to have excited considerable interest in Philadelphia, not only among the profession, but also among the newspaper reporters, judging from the head-lines, "Wonderful Surgery," "The Modified Cesarean Section Successfully Performed," etc., together with their detailed accounts of the steps in the operation, and the long lists they give of the physicians present. After all that, it seems somewhat cynical for the "Evening Post" of this city to record the woman's death under the caption, "The Victim of a Surgical Operation."

THE CHARITY ORGANIZATION SOCIETY.

From the First Annual Report of the Central Council, recently issued, an idea may be formed of the thoroughness and skillfulness with which the society has made its preparations for fulfilling its special aim, that of detecting impostors and preventing the "overlapping" of charity, that is to say, guarding against the same person receiving alms from any one organization while enjoying the benefits of another. The evils which the society has undertaken to eradicate are formidable, and we trust that it will be able to accomplish its object. We are encouraged in this hope by the personal character of its promoters, among whom we are glad to find Dr. S. O. Van der Poel (the president), Dr. Mark Blumenthal, Dr. Richard J. Derby, Dr. John J. Milhan, Dr. C. A. Bacon, Dr. P. W. Cremin, Dr. F. S. Selwyn, Dr. J. L. Barton, Dr. E. M. Kellogg, Dr. Henry Lassing, Dr. W. O. Moore, Dr. J. H. Emerson, Dr. S. F. Morris, Dr. H. G. Klotz, Dr. C. D. Scudder, Dr. T. C. Finnell, Jr., Dr. H. E. Crampton, Dr. F. J. Lynch, Dr. J. R. Taylor, Dr. Stephen Smith, and Dr. F. R. Sturgis, besides whom several members of the profession have contributed funds.
NEWS ITEMS.

A NEW PROFESSOR OF OBSTETRICS AT JEFFERSON COLLEGE.—Dr. Theophilus Parvin, of Indianapolis, who for some years has been a member of the faculty of the University of Louisville, has been elected Professor of Obstetrics and Diseases of Women and Children in the Jefferson Medical College of Philadelphia, succeeding Dr. Elmerslie Wallace. We congratulate Jefferson College on the acquisition of Dr. Parvin, who has long been favorably known as an obstetrician.

THE MEDICAL DEPARTMENT OF YALE COLLEGE.—At a meeting of the Corporation of Yale College, held June 27th, Dr. Thomas H. Russell, of New Haven, was appointed a professor in the Medical Department. It is the privilege of the Medical Faculty to designate the chair to which each professor is assigned. Professor Russell will, by vote of his colleagues, occupy the chair of Materia Medica and Therapeutics, which was made vacant by the transfer of Professor C. A. Lindsey to the chair of Theory and Practice, the latter having been vacated by the death of Professor Wilcox.

THE COLLEGE OF PHYSICIANS AND SURGEONS OF BUFFALO.—An injunction has been issued forbidding this concern to issue certificates or diplomas as a legally incorporated medical college, the legality of its incorporation being now before the courts.

THE KENTUCKY SCHOOL OF MEDICINE.—At the twenty-eighth annual commencement, held June 26th, the degree of doctor in medicine was conferred on fifty-one gentlemen.

THE ALUMNI ASSOCIATION OF TRINITY COLLEGE.—Dr. W. A. M. Wainwright, of Hartford, has been elected president of the association.

THE COLLEGE OF MIDWIFERY.—At the close of its first session, the College of Midwifery, designed for the education of midwives, recently granted diplomas to the following-named pupils: Katie E. Vanderbill, Marie Mount, Annetta Meyer, Katherine Mergerl, Bridget A. Mullody, Rosina Stuthfauth, Theresa Hall. Out of a class of nine, two failed to pass the examination. The lady whose name heads the list is said to have passed in a manner that would have been creditable to any medical student.

THE ASSOCIATION OF ASYLUM SUPERINTENDENTS.—At the recent meeting of the Association of Medical Superintendents of American Institutions for the Insane, held at Newport, Dr. John P. Gray, of Utica, N. Y., was elected president, and Dr. Pliny Earle, of Northampton, Mass., vice-president.

THE HARVARD ODONTOLOGICAL SOCIETY.—At the recent annual meeting the following-named gentlemen were elected officers: Dr. J. G. W. Werner, president; Dr. A. J. Colgan, secretary; Dr. W. E. Page, treasurer—all of Boston.

MEDICAL EXAMINERS IN CONNECTICUT.—The following appointments under the new law are announced: Avon, Dr. George R. Roberts; Berlin, Dr. E. H. Meade; Bloomfield, Dr. Henry Gray; Bristol, Dr. George S. Hall; Burlington, Dr. George R. Roberts; Canton, Dr. George F. Lewis; East Granby, Dr. G. W. Edwards; East Hartford, Dr. E. J. McKnight; East Windsor, Dr. H. C. Allen; Enfield, Dr. Edward F. Parsons; Farmington, Dr. Charles Carrington; Glastonbury, Dr. H. C. Bucy; Granby, Dr. G. W. Edwards; Hartford, Dr. G. G. Edwards; Hartford, Dr. H. S. Fuller; Manchester, Dr. J. N. Parker; Marlborough, Dr. N. C. Bucy; New Britain, Dr. B. N. Comings; Newton, Dr. Eli Warner; Plainville, Dr. T. G. Wright; Rocky Hill, Dr. Rufus W. Grissell; Simsbury, Dr. C. W. Wooster; Southington, Dr. W. G. Stedman; South Wind-
sor, Dr. William Wood; Suffield, Dr. J. K. Mason; West Hartford, Dr. Frederick S. Smith; Wethersfield, Dr. Abner S. Warner; Windsor, Dr. N. S. Bell; Windsor Locks, Dr. S. R. Burnap.

HONORARY DEGREES.—Yale College has conferred the honorary degree of M. A. on Dr. Henry B. Sands, of New York. Dr. Horatio C. Wood, of Philadelphia, has received the honorary degree of LL. D. from Lafayette College.

Dr. Henry J. Bigelow, of Boston, has been elected a Foreign Honorary Fellow of the Royal Medical and Chirurgical Society, of London.

Dr. John Swindenl was inaugurated Mayor of Albany, having successfully contested the election of Mr. Nolan.

THE PHILADELPHIA ABORTIONIST.—The man Hathaway, concerning whose career of crime we informed our readers last week, has been found guilty of the charge made against him, and has been sentenced to seven years' imprisonment, and to pay a fine of five hundred dollars and the costs of prosecution.

ABORTION-MONGERS UNDER ARREST.—Elgeron H. Wilcox and Augustus L. Meyers, said to be members of a firm manufacturing medicines for the purpose of producing abortion, doing business in Philadelphia, were arrested in that city last week, charged with using the mails for circulating their wares. The arrests were made by the United States Postal Inspectors.

PLEURO-PNEUMONIA having been reported as alarmingly prevalent among milch cows on Staten Island of late, the State Board of Health has called the attention of the National Cattle Plague Commission to the subject.

THE NEW JERSEY TOBACCO LAW.—On the first of this month the new law of the State of New Jersey, prohibiting the sale of tobacco in any form to persons under sixteen years of age, went into effect.

FALSE VACCINATION RETURNS.—Dr. W. F. Schwartz, of Pittsburg, Pa., has been arrested on a charge of defrauding the Board of Health by making false returns of vaccinations.

OBIITUARY NOTES.

BEVERLEY LIVINGSTON, M.D.—We are pained to have to record the death of this promising young physician. He died of diphtheria on Saturday of last week, at the age of thirty-eight years. Dr. Livingston took his medical degree at the College of Physicians and Surgeons in 1877, and subsequently studied abroad, devoting his attention particularly to diseases of children. At the time of his death he was one of the physicians to the Nursery and Child's Hospital, and a member of the Academy of Medicine, the Pathological Society, and several other organizations.

JEFFERSON PRATT, M.D., OF HOPKINTON, MASS.—Dr. Pratt died on the 26th ult., aged eighty years. He was the son of an officer in the army of the Revolution. For more than fifty years he practiced medicine in Hopkinton, and was a Representative in the State Legislature from 1839 to 1841. He was a member of the Massachusetts Medical Society, in which he took an active interest. He received his degree in medicine from the Berkshire Medical School.

ASA DANFORTH, M.D., OF NORWAY, ME.—Dr. Danforth died on the 10th ult., aged eighty-eight years. He was a native of Massachusetts, and received his medical education at Dartmouth College. He had been a member of the State Legislature, and was much esteemed.

W. E. SCOTT, M.D., OF MONTREAL.—Dr. Scott, for several years past the Professor of Anatomy in McGill College, died recently. He was a native of London, England, but emigrated to Canada early in life.
Proceedings of Societies.

NEW YORK OBSTETRICAL SOCIETY.

A stated meeting was held March 29, 1883, Dr. C. C. Lee, President, in the chair.

ONE OF THE DANGERS AFTER TRACHEOTOMY.—Dr. E. L. Partridge related a case illustrating the occasional danger of removing the tracheal tube after tracheotomy. [See p. 9.]

Dr. H. T. Hanks remarked that it had always seemed to him injudicious to remove the tube on the first, second, or third day, unless there was an absolute necessity for doing so. In the most unpromising case in which he had performed tracheotomy the tube was allowed to remain for six days, when it was removed, only to be replaced on the seventh. The child recovered.

The President asked Dr. Partridge what proportion of patients at the Nursery and Child's Hospital recovered after tracheotomy in diphtheria.

Dr. Partridge replied that there had been very few cases of diphtheria in the institution since his connection with it. He remembered but two in which the operation had been performed during the past two years, and in both of those the patients died.

Dr. A. Jacobi said that many years ago he performed tracheotomy on a child three or four years of age, suffering from diphtheria, and the breathing ceased almost completely immediately after the introduction of the tube. Upon withdrawing the tube, the child began to breathe again, but ceased entirely after the second introduction of the tube, and died. Post-mortem examination showed the thickened membrane doubled upon itself, and pushed back against the posterior wall of the trachea. It was evident that the child had been strangled on account of failure to cut through the false membrane after division of the tracheal wall. He knew of other cases in which the same accident had occurred, although not in his own practice, as one such lesson was sufficient. With regard to the President's question as to what proportion of patients with diphtheria recovered after tracheotomy, it involved a second question, namely, What was diphtheria? which he believed it was not the President's intention to have discussed on the present occasion.

The President related the following case, illustrative of one of the difficulties belonging to tracheotomy: This operation was performed at the Foundling Asylum, by Dr. O'Dwyer, on a boy aged two years and a half, believed to have diphtheria. As long as the tube was allowed to remain in situ the child breathed freely and did well, but, every time it was removed, breathing became embarrassed and suffocation was threatened. Dr. Wagner, and afterward Dr. Lefferts, made a laryngoscopic examination, and found a small polypus within the larynx far above the artificial opening, which, during the boy's efforts at respiration, after removal of the tube, became congested and enlarged, occluding the passage. The exact origin of the neoplasm could not be determined without the use of an anesthetic, but it was known to be far above the edge of the tracheal wound.

Dr. Jacobi remarked that if the origin of the neoplasm to which the President referred had been just at the upper edge of the tracheotomy wound, it would have been a condition not of uncommon occurrence. On the contrary, he looked upon it as almost a necessity under the circumstances. Granulations would spring up in every wound, particularly at the upper edge of the tracheal wound after tracheotomy, where no pressure whatever was produced by the tube, as occurred at the lower angle of the wound. Formerly he had been in the habit of leaving the tube in without examination for a week or ten days, and he then found on removing it that there was severe orthopnea or dyspnea caused by granulations that had sprung up from the upper edge of the wound, which, on removing the tube, occluded the lumen of the trachea. These could sometimes be seen hanging down through the fenestra of the outer tube after removal of the inner one, and were often detached by slight manipulation. If not interfered with, they were liable after a time to complicate the case seriously. He had, therefore, made it a rule to begin extirpation of the upper edge of the wound with the solid nitrate of silver about the fourth day after the operation, neutralizing the application immediately afterward. These growths were usually sessile, although they might become pedunculated.

The President remarked that the peculiarity of the case to which he had referred was the fact that the attachment of the polypus was at least so far above the edge of the wound that its insertion could not be seen.

The PORRO-MÜLLER OPERATION.—Dr. B. F. Dawson presented the vaginal portion of the uterus, with its appendages, which had recently been removed post mortem from the noted dwarf, Mrs. Burnell, upon whom the Porro-Müller operation had been performed by Dr. Richardson, of Philadelphia, in 1880.

A pathological report by Dr. Satterthwaite accompanied the specimen.

PROBABLE CEREBRAL ATROPHY IN AN INFANT.—Dr. Dawson also presented a specimen, for the history of which he was indebted to Dr. Swift, House Physician to the New York Foundling Asylum. The child was a year and nine months old at the time of death, and had been left at the asylum when six hours old. In March, 1882, it was sent out in good condition, except that it showed weakness in the legs. November 1st there was fever, with cough; December 27th the anterior fontanelle was observed to be closed, the fingers were flexed, the thumbs lying on the palm, and the legs were rigid, and were straightened with difficulty; the spine was flexible; there was no sign of hip disease. The child was returned to the asylum at the beginning of March, 1883, and came under his care. It was poorly nourished, and appeared no more developed than a healthy child six months old. The thumbs were clinched, the fingers were held tense and half extended, and the forearms were flexed. Nothing special was noticed about the lower extremities. The pupils were normal, the tongue was thickly coated, the bowels were free, and there was no elevation of temperature. On the 2d of March it was noted that there appeared to be constant general tonic spasm; the temperature was 101° F., and there was some evidence of pulmonary trouble on the left side. March 3d the temperature was between 101° and 102° F.; there was cough, but nothing more was observed. The child died quietly, March 4th, apparently of exhaustion. At the autopsy, which was made on the 6th of March, by Dr. Nortirop, the pathologist of the asylum, the body was found to be emaciated. There was only one tooth; the thumbs and the forearms were flexed. Examination of the brain showed on the convexity of the left side a cheesy nodule of the size of a pea; there was an atrophic condition of the middle third of each hemisphere. The veins were dilated. The spinal cord was apparently normal. The bronchial glands were large and cheesy, and the lungs sprinkled with tubercles. There was no consolidation. The heart was normal. The liver was fatty, enlarged, and tuberculous, and its cut surface showed a cavity of the size of a pea. The spleen contained large, cheesy tubercles. The kidneys appeared to be normal. There was ulceration of Peyer's patches. The pathologist considered the specimen unique with regard to the cerebral lesion.

Dr. Hanks reported further on the case of accidental punc-
ture of the gravid uterus during the performance of ovariotomy, related by the President at the meeting of November 21, 1882. The patient had been sent home at about the end of the fifth week after the operation, no symptoms of miscarriage having been manifest. But about the third day after her return home she began to complain of pain, and a bloody discharge appeared at the vulvar outlet. At the end of thirty-six hours the patient was rapidly becoming exsanguinated, notwithstanding vigorous attempts had been made to check the hemorrhage; the os externum was dilating, and, with the assistance of Dr. H. C. Coe, the patient was anesthetized, the os was more completely dilated with the egg-shaped, hard-rubber dilators, traction was made upon the child’s feet, and the decomposing body, becoming separated from the head, was extracted alone. Various means for extracting the head were then resorted to, but in vain; and, as hemorrhage had ceased, and as the patient was much exhausted, stimulants, ergot, and aponydes were administered, and she was allowed to rest until the next day, when the head was expelled without assistance, and she made a perfect recovery.

The President, who had performed the ovariotomy in which the accident referred to had taken place, said that the case went to show the possibility, with our present knowledge of antiseptic methods, of the patient’s complete recovery, and even a chance of her going on to full term. He therefore thought that Sir Spencer Wells’s advice—to perform Caesarean section at once in these cases, since the patient would almost certainly die when the gravid uterus was punctured—in the light of our present knowledge, should not be accepted.

PROLONGED INTRA-UTERINE GESTATION.—Dr. W. M. Chamberlain stated that three years ago he reported to the society the case of a young, healthy woman whose menstrual interval was regularly twenty-eight days, who menstruated last on the 3d of June, and was delivered on the 6th of the following May, making the duration of intra-uterine gestation eleven months and three days. This patient was pregnant at the present time with her fourth child, menstruation having ceased on the 23d of May, 1882. The duration of intra-uterine gestation, therefore, had already reached ten months minus three days. The occurrence of these circumstances twice in the same patient, he thought, established beyond doubt the fact that intra-uterine gestation sometimes continued beyond the ordinary term of nine months. He asked if it had ever been considered necessary in these cases to induce labor.

Dr. F. P. Foster remarked that, if the opinion that labor should be induced had ever been entertained, he supposed it had been based on the supposition that the child continued to grow after the ninth month, and was therefore liable to give rise to difficulty at the time of labor. Dr. Rodenstein, however, in a paper read before the society about a year ago, had expressed the view that the child, having arrived at the degree of growth incident to term, did not continue to increase in size. He asked Dr. Chamberlain if in his case the first child was of unusual size.

Dr. Chamberlain replied that it was not, and that delivery was normal, labor being of only three hours’ duration. The epidermis, the nails, and the powers of co-ordination, at the time of birth, however, seemed like those of a child over a week old.

Dr. A. S. Clarke referred to the case of a woman, married the second time, who had ceased to menstruate in November, spent the winter in Florida, returned May 1st, and in the following September consulted him, saying that she had felt signs of life on the fourteenth of that month, although she could not believe that she was pregnant. On examination, Dr. Clarke found her pregnant, and his opinion was confirmed by Dr. Skene, and also, in October, by Dr. Thomas, who stated that the size of the fetal head and other signs pointed to pregnancy of full five months’ duration. The woman was delivered on the 19th of March of the following year, making the term of pregnancy ten months and a half. Dr. Thomas and others who examined the patient had either mistaken a fetus of three months for one of five months, or else, as Dr. Clarke believed, was true the case was one of prolonged gestation.

The President remarked that so many elements of uncertainty entered into nearly all cases which had been reported as cases of prolonged gestation that they fell far short of positively settling the question under dispute—namely, whether intra-uterine gestation ever continued beyond the normal period of nine months; and it was a pretty safe rule to reject all cases as evidence except those in which it could be proved that but a single exposure to conception had taken place. The circumstantial evidence in Dr. Chamberlain’s case, however, was stronger than usual.

EXPLORATORY LAPAROTOMY THREE YEARS AFTER Battey’s Operation.—Dr. Dawson said that three years ago he related before the society a case in which severe ovarian and pelvic neuralgia was completely relieved by the removal of both ovaries, which were afterward found to be diseased. The Fallopian tubes were allowed to remain. Relief continued for two years; the woman went about her work in the enjoyment of good health. A year ago, however, she began to suffer again from pelvic neuralgia. And during the last few months the pain had become continuous, was exceedingly severe, and was growing worse, so that the patient had become clamorous for an operation, even at the risk of her life. From the fact that the pain was localized in the neighborhood of the Fallopian tube on the right side, and because it was believed that thickening of the tube could be detected, he decided, after consulting with Dr. C. C. Lee and Dr. J. B. Hunter, to make an exploratory incision, and, if the suspicions proved well grounded, to remove the diseased tubes; and for this purpose she was admitted into the Woman’s Hospital. Before proceeding with the operation a more careful examination was made while the patient was under the influence of ether, and it was not possible to recognize that there was enlargement of the tubes. He proceeded to make the exploratory incision through the scar of the wound made at the previous operation. The patient had had more or less peritonitis, and adhesions were found to be so extensive that it was almost impossible to recognize the tubes at all; but they were found to be in a condition of atrophy. Without further interference, the abdominal wound was closed, and the patient did well. He asked what the prospects of relief were in such a case. The pain was so severe that the patient had again had to resort to the use of opiates, which must in time undermine her health. Other treatment gave no relief.

Dr. Hanks asked whether the amount of chronic cellulitis and peritonitis from which the patient had suffered, and was still suffering, was not sufficient to account for her present pain. Dr. Dawson remarked that the pain was so circumscribed, and pointed so unequivocally to the region of the tube as its seat, which was also exceedingly sensitive to pressure, that it was inferred that the origin of the trouble was in that organ.

Committee on Publication.

THE AMERICAN DERMATOLOGICAL ASSOCIATION.—The seventh annual meeting will be held at Lake George August 29th, 30th, and 31st.

THE THIRD INTERNATIONAL ONCOLOGICAL CONGRESS, says the “Medical Times and Gazette,” will be held at Basle during the first week of September, 1884.
COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of March 1, 1885.

(Concluded from Volume XLVII, page 720.)

An important point in the history of typhoid fever, as it occurred in the country, was, that if the disease once appeared in a farm-house, it would, as a rule, attack more than one of the members of the family before leaving it, and this, too, when the physician knew of no other case within a mile or more of the afflicted family. Now, this is in entire accord with the admitted contagiousness, under certain conditions, of typhoid fever, not only by Trouseau, but by a majority of the most distinguished writers, among them that pre-eminent author and teacher, Austin Flint, Sr. The feature just noticed does not, as a rule, occur in the city, for in an immense majority of cases there will be but one member of a family attacked. Now, it has been said by a somewhat noted medical statistician, and concurred in by many others, that if a case of typhoid fever appears in a family it proves the existence of gas or filth in immediate relation with the residence. This is certainly explicit; but the question is, How happens it that, with such an efficient cause for the first case, it is only occasionally followed by others in the family? But, again, it may be asked if sewer gas—for this, after all, appears to be the great "enfer de bataille"—has not been, and is not yet excluded, by even the best plumbing, from the finest houses in this city or in New York? and, consequently, that tens of thousands of houses in both cities are in this fearfully exposed condition, how comes it that in Philadelphia, with nine hundred thousand inhabitants, the Board of Health has recently reported: but two deaths from typhoid fever in one week, and four in another, while diphtheria, said to be due to the same agencies, has prevailed at the same time to an alarming extent? The returns of the Board of Health of New York present similar statistics, showing comparatively fewer deaths from typhoid fever than Philadelphia, but a larger proportionate fatality from diphtheria and scarlet fever. That many physicians neglect to carefully examine these reports is well known, and yet they are the only available and reliable sources of information in regard to the character and movement of disease. If, instead of this reprehensible neglect, a diligent and discriminating examination were regularly made, it would do much to prevent misconception and error in regard to the actual causation of disease—a subject admitted by the most experienced and gifted minds to be one of equal difficulty and importance.

In this connection it must be stated that the reports of the Board of Health of Philadelphia show unmistakably that in the central portions of the city, where sewers and water-closets are most numerous, there is, as a rule, less typhoid fever and diphtheria than upon the outskirts, adjacent to the country; and this was the fact in regard to bilious remittent fever before it gave place to typhoid. Neither is it matter of surprise, for, just in proportion as the streets have been extended into the suburbs, graded and paved, houses erected thereon, and sewers constructed to carry off the surface drainage, a diminution of fever, whether intermittent, remittent, or typhoid, has been the beneficial result of such improvements. In support of this view we have the testimony of the late Dr. J. K. Mitchell, the distinguished and brilliant Professor of the Theory and Practice of Medicine in Jefferson Medical College, as follows: In December of the year 1850 he was called to consult with the late Dr. Gebhard and the writer in a fatal case of typhoid fever, in a house on Sixteenth above Summer Street—at that remote period an outskirts of the city. On his first visit the doctor informed us that he was scarcely ever called upon to visit a patient affected with typhoid fever in a large circle of practice in his own section of the city, but that nearly all such cases were, like the present one, in the suburbs, and in consultation. Now, the important fact in this connection is, that in his own central position sewers, water-closets, and the usual well in the yard, were almost everywhere, while in the suburbs they were comparatively few in number, the water-closet exceptionally rare. Does it not seem singular, then, that, despite the improved, the scientific, the sanitary plumbing of the present day, "nine houses out of ten on Fifth Avenue, New York, are not safe to live in"; and that all the actual appliances for the exclusion of sewer gas should be torn out, and others of an effective character be constructed in a separate building or annex? Dr. Mitchell also made allusion to the greater prevalence and fatality of fever in the country, as related to him by students from different sections of the United States.

In the paper by the writer upon this subject before the College of Physicians of Philadelphia, in 1879, Mr. Henry Dupont, in reply to a note, stated that his impression was that, in the years 1840, '41, '42, '43, there were but few cases of typhoid fever among the thousands of operatives and their families on the Brandywine, and this impression was corroborated by a note from Dr. Joseph P. Chandler, a practitioner of that section, in which he said that, while a very few cases seemed to owe their origin to local causes, his experience was perfectly in accord with that of the writer—that the disease nearly always showed itself in the houses of the farmers, and, that, no matter how well situated upon an eminence, with drainage in all directions from the residence, this did not secure them from attack. This is but a confirmation of the views long ago expressed by Dr. James Jackson, of Boston, and Dr. Nathan Smith, whose opportunities for observing the origin, development, and progress of the disease were exceptionally abundant. In a note sent to me a few days after the reading of the paper just alluded to, the writer declared that nothing was more erroneous than the current and popular opinions in regard to the causes of typhoid fever, and, in proof of this, cited the condition of the streets of one or two of the most populous and commercial cities of Africa, abounding, as they did, with every conceivable species of filth, emitting a stench nauseous to the last degree, and yet typhoid fever prevailed to a very slight extent. This statement is in accord with one quoted by Professor Hamilton in his paper, before alluded to, to this effect: that in Canton, filthy beyond measure, typhoid fever and diphtheria are almost unknown.

In further support of these views, a physician of New England has informed the writer that a few years ago he addressed letters to about fifty practitioners, in different parts of the State in which he practiced, asking their experience in reference to outbreaks of typhoid. The answers, with very few exceptions, were, that the rural sections suffered the most, whether in regard to proportionate number of cases or fatality. Thus it now appears, as it did in the time of Nathan Smith and James Jackson, that typhoid fever outbreaks occurred without the possibility of referring them to the conjectural local agencies now in favor. Physicians who have not enjoyed sufficient opportunities to observe the origin and progress of typhoid fever, and sanitarians, without medical experience, are the most positive in opinion in regard to the primary causes of typhoid fever; while Trouseau, Flint, Sr., Murchison, and many others of similar experience and sagacity, freely admit the obscurity of this subject, and the difficulty of determining the influence of local agencies in the production of typhoid fever as compared with causes of a general character, over which we have no control, as in telluric or atmospheric conditions, involving thermometric, hygrometric, and electric states and their influence, singly or combined.

As pertinent to this point, reference may here be made to an article in the "Medical and Surgical Reporter" for January 1,
1881, entitled "The Limited Effects of Sanitation," from the pen of Dr. John Syer Bristowe, President of the Society of Medical Officers of Health, as follows: "If we look to the remarkable influence which simple variations of temperature and peculiarities of season exert on the mortality returns, in respect both of the number of deaths and the character of the fatal diseases, and compare therewith the comparatively small effect on the death-rate of even one of the most fatal of the zymotic diseases, or with the insignificant influence of diphtheria from enteric fever, diphtheria, pneumonia, puerperal fever, and other affections over which sanitary science is supposed to exert a specially valuable influence, we can scarcely avoid, I think, seeing that, on groundless grounds, the deaths saved directly by the sanitary labors on which we are engaged must, under any circumstances, be so few annually as to produce no distinct and unmistakable effect on the mortality rates." This sincere and ingenious avowal of opinion by one so distinguished as an authority in medical science is well entitled to the serious consideration of the enthusiasts who never tire in predicting the suppression of the diseases in question so soon as sewer gas and filth are banished from the houses and premises of our citizens; while it is a notorious fact that lavish expenditures of money, by public authority and by citizens, have for several years past been made in Philadelphia without any perceptibly important result as the consequence. In the paper of Professor Hamilton it is distinctly stated that during a certain period, the increased mortality in New York could not be found in the condition of the streets, for at that time they were unusually clean; nor can the unusually severe outbreak of diphtheria now prevailing in our own city be attributed to the current local agencies. If, indeed, the primary causes of typhoid fever, diphtheria, and scarlet fever in cities be due to the influence of sewer gas and filth, then, in fact, our citizens can have little hope of an early exemption from these maladies. Yet on this score there is no occasion to despise. Fifty years ago typhoid fever was not common, but intermittent and billious-remitting prevailed in the city, yet only to a moderate degree compared to the suburbs and the adjacent country. These are not regarded as special filth diseases, while typhoid fever, diphtheria, and scarlet fever are by many so considered. At the remote period alluded to, some attention was given to cleansing the streets, but there were no such exertions and expenditure of money; even in proportion to the size and population of the city, as are now customary; and as to inspection of dwellings, out-houses, wells, and the premises, it was almost unknown. That constant attention, by the authorities and citizens should be given to maintain cleanliness in every place, and by all possible means, no one will deny: but, when all this has been done, what comparison can there be between the condition of a large city and any well-managed rural section in this point of view? Under the most favorable circumstances, the sources of filth contamination in a city are as ten to one compared with the country, and this is manifest in the single fact that the ground on which a city rests is, of necessity, well-nigh riddled with wells for the convenience of families. During the past ten or twelve years the average weekly deaths from typhoid fever in this city have been from seven to eight, as before stated. If this disease had prevailed here, in frequency of attacks and fatality, in proportion to population, as the writer has known it to do in the country, forty to fifty deaths per week would have probably occurred. The same feeling of gratification that the late Dr. Joseph Parrish manifested and expressed when informing his class of the slight mortality from bilious fever in this city, as compared with the country, has been experienced by the writer in regard to typhoid fever in this city as compared with what is seen from time to time in the country. The city of Philadelphia, as shown by the reports of the Board of Health, still maintains its title as one of the healthiest of the large cities of the world; nor is it good policy, under any circumstances, to do or say aught to inspire citizens with dread, and induce strangers, who may have occasion to visit us on business, or otherwise, to regard Philadelphia as unhealthy, and therefore to be avoided.

[After the reading of the preceding paper:]

Colonel Waring, who was present by invitation, was called upon by the chair to discuss the subject considered in the paper. He remarked that he desired to say one word for sanitary engineers with regard to the cause of typhoid fever, and this was that they had long since abandoned the opinion that sewer gas was the cause of the disease. He thought it very important that filth should be gotten out of the way so as not to become a source of contamination to the water-supply. The literature of the subject seems to prove that typhoid fever in the country is due to drinking-water which has become contaminated. Cleanliness is safe and important, and efforts should be always made to secure it.

Dr. Hamilton said the quality of the drinking-water remained essentially the same from year to year, whether typhoid fever prevailed extensively or was absent; so, also, in regard to vegetables and roots for family use. These are laid up every season, generally in trenches, covered with clean straw, and earthed over. On consulting several German monographs, Dr. Hamilton had found the experience of the writers to conform with his own—that males suffered more from typhoid fever than females, and that from the fifteenth to the twenty-first year, the period of rapid growth, the danger, in case of an attack, was augmented.

Dr. J. M. Keating said that the elaborate paper we have just heard read might mislead some of its hearers into the supposition that sewer gas was considered a cause of typhoid fever. It may be well for us at once to dispel such an idea, and to couple with the paper just heard the emphatic indorsement of this body that sewer gas, as far as typhoid fever is concerned, is simply a vehicle by which the specific germ may enter the system of one prepared to nourish and develop it. There is no need to debate the question as to the greater importance of infected drinking-water; the incidents in the paper just heard, the greater prevalence of the disease in the rural districts where privy wells contaminate the drinking-water, and the remarkable statistics of the New England country towns, where the wells for sewage and drinking purposes are under one roof, the fact that these localized epidemics are usually traceable to one primary case entering the village, are all sufficient in themselves. But though sewer gas may not always carry the germs of typhoid fever, it has a poison of its own equally terrible in its consequences. The modern improvements in house-drainage—indescribable comforts where properly constructed—are, unfortunately, too often the means of carrying the most deadly vapors directly into the abodes of luxury and wealth. At these hours, when depressing influences have disarmed their victim, these noxious gases steal insidiously into his chamber and do such violence as to render fatal, by the most serious complications, such diseases as are otherwise mild and harmless in themselves. Whether the concentrated miasm from paludal emanations or the outpouring gases from a sewer through siphoned traps, the unconscious sleeper breathes poisons as potent in their devitalizing effects as if he inhaled the germs of typhoid fever in their purity or drank water impregnated with the excreta of typhoid cases. Sewer gas is not necessarily a cause of typhoid fever, except when it carries its germ, but it is the most potent cause of the 'typhoid state'; and there is a decided choice between these two evils—in favor of the former.
Early manhood carries with it a decided predisposition to typhoid fever. I have recently read with great interest an article in the "Nineteenth Century," by General Sir Frederick Roberts, on the recruits for foreign service in the English army, in which statistics were given to show that the large mortality from typhoid fever in young recruits rendered advisable the considerations as to whether it was not better for foreign service to take only such as had recruited early and survived this period, or to recruit only from those who had passed the age when the disease was most liable.

The typhoid germ is certainly more deadly if its vehicle be poisonous also; and it becomes our duty to add an earnest appeal to that which seeks by proper legislation to give us pure air for our children to breathe, and pure, uncontaminated water to drink.

Dr. J. G. Richardson remarked: I am well aware that the evening is too far advanced for me to attempt to discuss the important subject of Dr. Hamilton's paper, and I will, therefore, content myself with suggesting how two of Dr. Hamilton's illustrative cases may be very plausibly explained in accordance with the modern views respecting the danger to human health from impure drinking-water, foul sewer air, and other grave sanitary errors.

Dr. Hamilton mentioned the case of the mother of a family who contracted typhoid fever away from home, and brought it back to her farm-house, where several members of the family seemed to take the disease from her, and argued that this circumstance proved that the infection of typhoid fever was not carried by sewer gas, because in this instance no sewers existed near the place. The true explanation of this seeming anomaly is, I believe, however, that, while typhoid fever is sometimes carried by sewer gas, it is more frequently conveyed in drinking-water contaminated by sewage, and that in this case the diarrheal discharges of the mother were emptied near enough to the family well to soak through the ground into it, and, by polluting the drinking fluid, transmit the disease to other members of the household.

That some such mode of propagation may have existed is shown by a remarkable fact related by Professor Flint, upon whom Dr. Hamilton relies as an authority against the dangers of sewer gas, which is briefly as follows: A young man, traveling by stage-coach in Vermont, was taken sick, and left at a wayside inn in a small village. His complaint soon proved to be typhoid fever, and in a short time the disease appeared in each of the neighboring houses, the inhabitants of which used water from the tavern-keeper's well, except one, whose residents had quarreled with the landlord, and, consequently, went elsewhere for their water-supply.

In the light of recent sanitary science, then, it appears that many people, many whole families, in rural districts, suffer from typhoid fever because they drink well-water polluted by direct mixture with faecal matter containing the specific fever germ, which soaks through the soil, often directly, into the well; while in cities a few persons, relatively, are attacked with typhoid fever, and many with diphtheria, etc., by inhaling poisoned sewer air from stationary wash-stands and other modern conveniences. There are, probably, one hundred thousand villages and farm-houses in the United States to-day where the cesspools feed the wells in this abominable manner, and such wells surely in their turn feed, from time to time, the church-yards in their neighborhood.

Again, Dr. Hamilton inquires, Why is it, if sewer gas is the cause of both typhoid fever and diphtheria, we now have, according to the late reports of the Board of Health, only two or three deaths per week from the former disease, and thirty or forty from the latter? The obvious answer is that sewer gas can only convey the materies morbi (the disease germ, as I believe it is) with which it is freighted, and at the present time sewer air in but few houses is contaminated with typhoid-fever poison, while in many it is loaded with diphtheria germs. Precisely as drinking-water might contain both lead and copper in varying proportions, and, accordingly as one or the other temporarily predominated, would persons who imbibed the fluid be liable to exhibit the symptoms of lead palsy or of copper poisoning.

Although I am not yet prepared to inclose the dictum of a late English hygienist, who declares, "For every death from typhoid fever, somebody" (meaning some plumber, architect, or sanitary engineer) "ought to be hung," I do hope and believe that the time is not far distant when at least the charge of criminal negligence will lie at the door of every physician, who, after being warned of the occurrence of one case of typhoid fever, diphtheria, etc., in a dwelling, does not immediately endeavor to guard the other residents of that house against the germs (or poison, if you choose) of infectious disease, by a diligent search for the sanitary defects in the water or milk supply, or in the disposal of sewage, which will almost certainly be discovered.

I have spoken of the germs of typhoid, diphtheria, etc., entering sleeping apartments from stationary wash-stands in spite of traps, and in this connection I desire to show the Fellows of the college just how, as I conceive, these poisons may penetrate through such mechanical contrivances. Here I exhibit the ball of an ordinary Bower trap, covered with a coat of fungous growth, and here a portion of the slimy coating from one of the pipes of similar structure. Since these form a continuous lining quite through the trap, it is obvious, I think, that it may have crept up from the sewer itself, thus forming on the inner or house side of the trap a new starting-point for the evolution of disease germs, against which, of course, the most perfect water seal is absolutely no protection. This, I believe, is what really occurs in a multitude of instances, as I pointed out in a paper entitled "Why Sewer Traps are Unreliable" in the "Medical News" for September 2, 1882. The true remedy for the dangers of sewer-gas poisoning is, therefore, I think, as explained in that article, to be found in sterilizing the whole interior of our traps and waste-pipes with slow currents or drippings of powerful disinfectants, such as the salts of iron, zinc, mercury, or arsenic, "just as the shores of the Dead Sea and the banks of certain small streams are sterilized, by mineral ingredients or poisonous metallic substances from manufacturing refuse, with which their waters are mingled."

Reports on the Progress of Medicine.

OPHTHALMOLOGY AND OTOLOGY.

By CHARLES STEDMAN BULL, M. D.

LECTURER ON OPHTHALMOLOGY AND OTOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR IN~

ARTY; OPHTHALMIC SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, AND TO THE NURSERY AND CHILD'S HOSPITAL.

OPHTHALMOLOGY.

fibers which preside over the contraction of the pupil are to be found either in the optic tracts or in the central terminations in the corpora geniculata and corpora quadrigemina of the higher animals, or in the corpora bigemina of birds. 2. While these fibers begin in the retina and run in the optic nerve, they enter behind the chiasma directly into the central gray matter surrounding the cavity of the third ventricle, and run toward the nuclei of the oculomotor nerves, whence they again return toward the periphery in the trunk of these nerves. 3. Throughout their entire course in the central gray substance these fibers presiding over the contraction of the pupil are uncrossed. 4. Each eye possesses an independent reflex curve or band, which runs through the optic nerve, the corresponding half of the central gray substance, the nucleus and trunk of the oculomotor on the same side. 5. Between the reflex bands or fibers of the two sides there is a connection, by means of which the reflex action of one eye can be carried to the other. This connection or communication is maintained by means of commissural fibers between the nuclei of the two oculomotor nerves. 6. The centers for reflex contraction of the pupils do not lie at the bottom of the third ventricle, as Hensen and Völkers believed, nor behind the corpora quadrigemina, as Adamkiewicz thought, but they are, in all probability, located in the nuclei of the oculomotor nerves. 7. There are no centers for the contraction of the ocular muscles in the bottom of the third ventricle, at least in the sense assumed by Hensen and Völkers. 8. The changes in the position of the eyes, which, together with general disturbances of motility (disturbances of equilibration and forced movements), always appear after irritation or destruction of the region of the third ventricle, are in character exactly similar to those changes in the position of the eyes observed after destruction of the semicircular canals, or of the olivary bodies of the medulla oblongata; they merely prove that this region, like the organs just mentioned, exert an influence upon the entire sphere of motility of the animal, including the eyes. 9. The centers for the voluntary movements of the eyeball must be located in the nuclei of the nerves which innervate the ocular muscles, since static changes in the position of the eyes are only produced by destruction of these nuclei, or of the roots proceeding from them. 10. The localization of a center for accommodation in the region of the floor of the third ventricle can not yet be regarded as finally settled. 11. The dilating effect on the pupil of painful irritation is not by means of the sympathetic nerve, but occurs independently through the fibers of inhibition or hindrance of the light reflex. 12. The so-called reflex papillary rigidity, in all probability, is caused by such pathological processes as interrupt the path of the light-reflex in its course from the optic chiasma to the nucleus of the oculomotoris.

On the Frequency of Papillitis in Sympathetic Ophthalmitis.—Benson (“Ophth. Rev.,” May, 1883) reports a well-marked case of this sort in a female child, aged eight, occurring five weeks after a penetrating wound in the ciliary region of the other eye. Benson thinks that, if it be conceded that papillitis in the injured eye is followed by papillitis in the sympathizing eye, its occurrence should be very constant, for it is hardly possible that an eye so injured as to produce sympathetic inflammation in the fellow-eye could escape being itself the subject of papillitis, since the disc shows signs of inflammation (microscopic, if not ophthalmoscopic) in almost all the severe inflammatory affections of the globe. Even in comparatively superficial wounds or ulcers of the cornea, and in iritis, increased haziness of the disc can very often be observed with the ophthalmoscope. The fact that a very considerable degree of papillitis may exist without producing any loss of sight or other subjective symptoms would render it very possible for such a condition to be overlooked; for not until some of the subjective or external symptoms of inflammation appeared would the patient present himself for examination. Hence, it is advisable, in all cases where sympathetic inflammation is feared, to examine systematically, and at short intervals, the papilla of each eye, and note its condition.

A Case of Retinitis Alberschens Punctata.—Barnett (“Arch. of Ophth.,” xii, 1) reports a case of this nature in a woman, aged fifty-eight. The trouble began suddenly as a dark spot in the center of the visual field of the right eye. This condition remained for more than a month, and then the scotoma began to break up, and when Barnett saw her the visual field was intact and color perception normal, with vision of 2/6. In the region of the macula lutea, and occupying the space between this and the optic disc, as well as somewhat below the latter, there were numerous very small, yellowish-white dots. These dots were not always round in shape, but frequently ovoid, and usually had a sharply-defined outline. One of the large retinal veins below the disc was very tortuous, while a smaller one, just above it, became lost, and its place was occupied by a white band similar in appearance to the dots. The peculiarities of this affection seem to be that the alterations are confined almost exclusively to the region between the macula lutea and optic disc, and are in the retina, and most probably confined to the inner layers.

Perception of Colors at the Periphery of the Retina.—Charpentier (“Archives d'ophtalmologie,” Jan.-Feb., 1883) has been making some investigations into the acuity of the color-sense at the periphery of the retina, and draws the following conclusions: 1. It is certain that the peripheral parts of the retina are not achromatopic; they are capable of perceiving all the colors, or, at least, the primary colors. 2. In order that the periphery of the retina may perceive colors, the latter must be very intense. The acuity of perception of colors diminishes progressively from the center to the periphery of the retina. 3. The condition of intensity is the one necessary factor, and one need not employ very large colored surfaces. 4. If the retina is not achromatopic at the periphery, it may be dyschromatopie; and it is in the sense that it perceives the center much better than the colors; but it might be so in another sense, if it perceived certain colors more easily than others, comparatively to the center or at a point less eccentric.

A Contribution to the Zonula Question.—Dussier (“Klin. Monatsbl. für Augenheilkunde," March, 1883) considers that the subject of the origin and distribution of the zonula fibers should be reconsidered ab initio. To determine what the zonule is, and whence it takes its origin, we must be enabled to follow out the entire course of its fibers in preparations under the microscope. His investigations have demonstrated to his satisfaction that the fibers of the zonule never reach the ora serrata in adults, but in the new-born they approach this region somewhat more closely. Each fiber is attached to the internal limiting membrane of the pars ciliaris retinae, and beyond the ora serrata not a single zonule fiber can be followed. The zonule, both of adults and the new-born, has absolutely nothing to do with the vitreous. His final conclusions are as follows: The zonule is closely applied to the smooth portion of the ciliary body and to the ciliary processes, and, when carefully detached, presents an exact impression of these processes; it has no connection with the hyaloid membrane at any period of life; no cells or nuclei, arranged in regular order and pointing to the existence of an endothelial membrane of the zonule, have ever been demonstrated; hollow spaces probably exist between the zonule and the vitreous, but not between the zonule and the ciliary processes.

The Effects of the Electrode Light upon the Eye.—
Emrys-Jones ("Ophth. Rev.," April, 1883) reports two cases of severe conjunctival irritation and inflammation produced by too prolonged exposure of the unprotected eyes to the electric light. He considers that the symptoms are decidedly due to the brilliancy more than to the radiant heat of the lamp. It is easy to understand that retinal mischief may follow a too prolonged exposure without the protection of colored glasses.

The Operation for Congenital Blepharoptosis.—Eversbusch ("Klin. Monatsbl. für Augenheilk.," March, 1883) describes the manner in which he operates for congenital blepharoptosis as follows: He introduces Snellen's blepharostat with the plate pushed as far up behind the lid as possible, and, before screwing down the half-ring, he pushes the skin as far down toward the eyelid margin as possible, so that, after closure of the spring, not only the tarsal portion of the upper lid, but also the retro-tarsal fold, is confined within the limits of the instrument. Then with a scalpel he divides the skin and the layers of orbicularis fibers the entire length of the lid parallel to the lid margin and midway between the latter and the eyebrow. He then dissects carefully the skin and subjacent muscular fibers upward and downward for an extent of about 4 millimetres free from the underlying tissue, so that the upper fold of transmission and the insertion of the levator into the tarsus can be reached and laid bare. He then passes each end of a fine suture through a fine, moderately curved needle, and introduces one of these needles through the middle of the insertion of the levator, so that the points of entrance and exit are about 2 millimetres from each other, and the point perforated is thus embraced in a still open loop. This needle, together with the other needle, is then introduced downward between the tarsal plate and the orbicularis, from 2 to 3 millimetres distant from each other, in such a manner that they are brought out to view exactly in the middle of the free border of the lid, and about 2 or 3 millimetres from each other. In the same way similar sutures with double needles are introduced through the temporal and nasal sections of the tendon of the levator, so that the latter is included in three loops. Before the ends of these sutures at the edge of the lid are tied, the incision in the skin and muscle is to be closed by three vertical sutures, and the blepharostat is to be removed. A protective bandaging of borated cotton is to be applied, and the other eye also bandaged. This operation is practically an advancement of the levator muscle, except that the line of insertion of the tendon is not divided. Eversbusch uses carbolized catgut for sutures, and ties them at the margin of the lid over or by means of glass or mother-of-pearl beads, to prevent their cutting too deeply into the lid margin. The author recommends the operation solely for those cases in which the blepharoptosis is congenital.

Arterio-venous Anæmia in the Retina.—Fuchs ("Arch. of Ophth.," xii, 1) reports a case, apparently of this nature, in a man, aged twenty-six, who was struck on the right eye by the branch of a tree in October, 1859. There was a small wound at the inner corner of the eye, and the eye was bloodshot for several weeks. Vision was not perceptibly diminished at first, but after six months it began to fail. In 1881 he had V = 3/4, but soon after he could only count fingers at 3/4 of a metre eccentrically. Externally, the right eye appeared normal, the media were clear, and the papilla and upper half of the retina were normal. Below these were two large vessels which were very conspicuous. The vein passed almost perpendicularly downward, and the artery, to the outer side of the vein at first, afterward passed over the vein and ran downward and inward. In the first half of its course there were only isolated dilatations; between these it was narrower than normal. The inferior half was distinguished from the superior in that it widened suddenly. Both artery and vein disappeared in a large, some what ill-defined disc, which was prominent, covered with blood-spots, and very dark. Both artery and vein were of the same dark color, and could only be distinguished from one another by their branches. There was no spontaneous pulsation; a slight pressure made the large vein and a large branch of the artery pulsate. In the round tumor pulsation could not be produced. In the region of the macula lutea there was a white, star-shaped figure, similar to that of Bright's retinitis. In the direction of the continuation of the rays of the star were also white spots. On the inner side of the retina was a band-like figure, which grew narrower as it passed away from the papilla, and at the same time bent downward. It had a silvery reflex, and its color could only be compared to that of those figures which are sometimes found in the region of the macula, in nevritis ex tumore cerebri. The round spot in which both the large vessels ended seemed to be a spurious aneurysm. The injury must have caused a rupture of both vessels, and a consequent pouring of their blood either into or under the retina. The latter seems the more probable, since the spot was too large to be in the retina itself. The reason why there was not further extravasation of blood in the tissues was because the retina and choroid probably became adherent to each other, and thus acted as a wall of retention.

Melanoma of the Iris.—Fuchs (ibid.) reports a typical case of this rather rare disease in a woman, aged seventy-five, who had an inexcptile se include cataract. There was a black-brown prominence visible at the supero-nasal quadrant of the papillary margin, 4 mm. long, which projected from the lower surface of the iris into the pupillary space. It projected above the papillary margin about 1 mm, during contraction, and 2 mm. in dilatation of the pupil. There was evidently a larger tumor in the posterior chamber, for the iris in this region was crowded forward. The tumor and neighboring parts of the iris were excised through an incision made with a narrow Graefe's knife, and carefully examined. The iris was found very strongly pigmented, not only in the pigment cells of the struma, but also by large numbers of free pigment granules. The proliferation directed toward the papillary margin formed a black wedge, which almost reached the free border of the iris, and lay rather nearer the posterior than the anterior surface of the iris, and seemed to incline the sphincter. A similar wedge of pigment extended into the iris in a centrifugal direction; passing obliquely forward, it reached at one point the anterior surface of the iris. The main proliferation extended backward, and a broad black band perforated the posterior limiting layer and the uveal leaf of the iris, so as to spread behind it and form the tumor observed. The tumor consisted of an accumulation of cells which were so deeply pigmented that they formed a uniform black mass. The tumor possessed neither blood-vessels nor struma. At the central side the posterior limiting membrane of the iris was partly reflected upon the surface of the tumor. There was no trace of the uveal pigment of the iris.

Pulsating Tumor of the Orbit, followed by a Cure.—Gayet ("Ann. d'oculistique," Jan.–Feb., 1883) reports a case of pulsating tumor in the orbit of a shoemaker. Several days before Gayet saw the patient the latter had received a violent blow upon the right cheek from a suddenly opened door. The blow was so violent as to cause unconsciousness. For twenty-four hours he complained of nothing, but then noticed a noise in his head and a slight failure of vision. These symptoms somewhat rapidly increased, and, in addition, the right eye began to project, and he had a sort of dull, stunned feeling in his head, and diplopia. When he presented himself at the hospital there was marked exophthalmus, ptosis, vision very much reduced, but no ophthalmic evidence of any trouble. There was an intermittent systolic murmur and a visible pulsation of the eyeball,
On the third day after, there was very marked chemosis of the ocular conjunctiva and edema of both lids, and the latter rapidly spread over the entire right half of the face and invaded the left lower eyelid. From January 24th to February 1st, digital compression of the right common carotid was maintained daily for from one to two hours. During the compression the bruit and pulsation disappeared, but reappeared on the cessation of the compression. The patient was under observation till April 9th. On February 10th, a small expansive, pulsating tumor for the first time was distinguished in the upper and inner part of the orbit, which slowly became more and more circumscripted, and the symptoms slowly subsided. On February 15th the first ophthalmoscopic signs of an exudative retinitis with hemorrhages were discerned. On the 9th of April not a trace of the tumor remained, but there was some slight erosion of the cornea, and a small amount of convergent strabismus. The condition in the retina remained unchanged. Gayet's conclusions are as follows: 

1. There was a perforation of the right internal carotid artery in its passage near the cavernous sinuses, the result of a fracture of the orbit. 2. An arterio-venous aneurysm was formed. There was consecutive dilatation of all the branches of the ophthalmic vein and a tendency to the formation of a venous tumor.

4. The cure was due to some fortunate coagulation, but exactly where Gayet does not undertake to say.

**The New Method of Extraction of Cataract without Excision of the Iris.**—Galezowski (“Rec. d'opital.,” Feb., 1883), in advocating this method of operating, takes occasion to review the results of the 1,020 cases operated upon during the last nine years. He concludes: 1. That the excision of the iris does not prevent the occurrence of inflammation in the extraction of cataract. 2. It is often the cause of secondary cataracts.

3. The scleral or sclero-corneal wounds are much more dangerous for the definite results of an operation than corneal wounds. In operating, he makes his puncture and counterpuncture in the sclero-corneal limit, but he makes the summit of the flap at 2 mm. from the scleral border. The wound is thus elliptical, the coaptation is easier, and the cicatrization more rapid. The pupil dilates under pressure of the lens and lets the latter through easily; the iris then returns to its own place, or, if not, it may be pushed back with a smooth stylet. The coaptation of the lips of the wound is complete in twenty-four or forty-eight hours. The results of this method of operating are relatively better than we obtain by excision of the iris.

**Sympathetic Glaucoma.**—Galezowski (“ibid.,” April, 1883) reports a case of subacute sympathetic glaucoma in a man aged forty. Three years before, the patient had received a serious lesion of the right eye by a blow from a stick of wood. There was a violent inflammation, followed by loss of vision and, finally, complete atrophy of the eyeball. About three years later the patient noticed occasional attacks of diminution of vision in the left eye, with transient injection of the vessels, and at the same time the atrophied eye became injected and sensitive. Between October, 1882, and February, 1883, he had several such attacks, which were transient, and soon subsided. At the latter date he began to have severe pain in the good eye, accompanied by profuse lacrimation and periodical clouding of the vision toward evening. On examination, the atrophied eyeball showed a horizontal cicatrix across the remains of the cornea, injection of superficial and deep vessels, and sensitiveness to the touch. The left eye showed all the symptoms of a typical subacute glaucoma, with tension +1, normal vision, and marked narrowing of the visual field outward and downward. The atrophied right eye was immediately enucleated, and on the following day the pain in the left eye disappeared and did not return. The symptoms of irritation also subsided, but the increased tension remained. On the 31st of February an iridectomy was done upward, and the wound healed by first intention. On March 11th the vision was normal, he read Sn. I, and the color perception was completely restored. The field of vision had sensibly increased in extent, though there was still a marked concentric limitation.

**Crosed Amblyopia and Hemianopsia in Cerebral Lesions.**—Grasset (“ibid.,” March, 1885), in taking up this subject in a short communication, reviews briefly certain published cases of this nature, thirteen in number, in the light of the scheme of explanation offered by Charcot. And of the modified one advocated by Féré. He rejects the scheme of Charcot, because, according to it, hemianopsia could only be produced by a lesion of the optic tracts. On the other hand, the scheme of Féré does not offer any explanation of the facts of crossed amblyopia. At no point of his schematic representation is there any point of union of the external and internal nerve fibers of the same eye. Having abandoned the schemes of both Charcot and Féré, he proceeds to propose a new scheme of explanation for these cases, as follows: The theory of the semi-decussation in the chiasm is not apparently contradicted by the facts: lesion of the optic tract behind the chiasma causes hemianopsia. Hence, 1. The internal fibers of the optic nerves decussate in the chiasm; while the external fibers continue straight on. 2. The external fibers decussate behind the chiasm (near the tubercula quadrigemina) in such a manner that the decussation is there complete for all the optic nerve fibers, and that in each internal capsule all the fibers coming from the opposite eye are found united. But when the lesion exists in the cortex, as in the occipital lobe, there results bilateral hemianopsia, as in lesion of the optic tracts. To explain this, a new decussation of the external fibers of each retina would be necessary, and then each hemisphere contains the homonymous fibers of the two eyes; hence, 3. The external fibers would undergo a second decussation beyond the internal capsule before reaching the convolutions, so that each occipital lobe would contain the external fibers of the eye of the same side and the internal fibers of the eye of the opposite side. This Grasset offers as a scheme of explanation in lieu of those rejected.

**Deep Ulcers of the Cornea and Their Antiseptic Treatment.**—Guaita (“ibid.,” April, 1888) finishes in this number his series of papers upon deep ulcers of the cornea and their antiseptic treatment, and arrives at the following conclusions: In perforating ulcers of the cornea, the antiseptic medication by boracic-acid spray and dry salicylated dressings, with an ointment of eserine, produces certain and rapid cures. In ulcers of the cornea, produced by wounds from finger-nails, this medication, with eserine or atropine, gives equally good and sure results, though not so rapid as in the first class of cases. In the sloughing ulcers of the cornea, antiseptic medication gives good results in a large number of the milder cases. In severe cases, after Saemisch's incision, this treatment hastens cicatrization, and thus aids in preventing the formation of an opaque staphyloma.

**A Case of Cysticerces Cellulose in the Vitreous; Extraction of the Parasite; Preservation of the Eye and of the Visual Power Present.**—Haase (“Arch. of Ophth.,” xii, 1) reports a case of intracocular cysticercus in a man aged twenty-one. There was a detachment of the retina of the right eye, and in the center of the detached portion a perforation had occurred, from the opening of which protruded the head and neck of a cysticercus in the most active motion. The parasite was extracted by the meridional scleral section. The globe having been drawn inward as far as possible, an incision was made into the conjunctiva, 1-5 cm. long, as far back as feasible, and detached it on both sides of the incision, so as to expose the sclera. The hemorrhage having been completely arrested, an incision was made with a small cataract knife, 10 mm. long,
down to the vitreous. A small pair of iris forceps was then introduced twice into the vitreous, in order to seize the parasite, but in vain. The wound was then widened by a few millimetres with scissors, and the cysticercus was then removed. The wound in the sclera and that in the conjunctiva were then united by two catgut sutures, and a pressure bandage applied. The operation was done under all anti-piction precautions, including the spray, and the healing followed without the slightest reaction.

On the thirteenth day vision was the same as before the operation—that is, the patient distinguished movements of the hand at three feet.

**Lemons of the Optic Nerves in Cranial Deformities.**—Hirschberg ("Centralbl. f. prakt. Augenheilk.," Jan., 1883) reports seven cases of disease of the optic nerve occurring in patients with deformed skulls, either congenitally or acquired in the first months of life, mainly from too early ossification of the sutures. The first case was that of a boy, aged five, whose cranial defect was scaphocephalus with premature sagittal synostosis. The nasal septum was deflected to the right side, with extensive widening of the bones of the nose, which pointed to a possible deviation in the os planum of the ethmoid, and a probable meningitis occurring in early life. The frontal vault was enormously developed. In both eyes there was choked disc in the retrogressive stage. Eight years later Hirschberg saw the child again. The eyes were prominent, the left diverged: R. E., V = 9/3, with a marked concentric limitation of the field of vision; L. E., no perception of light. Optic discs in both eyes of a greenish-white color and of indistinct contour. The second case was in a girl, aged three, with a marked protuberance in the center of the frontal bone from hyperostosis or synostosis of this bone, which had been noticed for more than two years. In both eyes there was inflammatory atrophy of the optic nerve, which had probably existed for more than a year, as the very marked defect of vision had existed for that length of time. The degree of vision could not be determined, but the child could pick up pieces of paper from the floor. The third case was in a boy, aged fifteen, with a brachycephalic skull with sagittal hyperostosis. The distortion of the skull and the defective vision date from very early childhood, at which time he had convulsions and became unconscious. R. E., 9/6; L. E., movements of the hand. Both optic discs gray-white, cloudy, excavated, and atrophic. The fourth case was in a boy, aged four and a half, with a skull of marked leptcephalic character. The child has always been wild, and had frequently fallen, probably owing to defective vision. He had been almost completely blind for nearly three years, and had frequently complained of severe headache. There was inflammatory atrophy of both optic discs, probably from meningitis. Vision was reduced to perception of light. The fifth case was in a young man, aged twenty, who had since birth a very high, narrow skull. R. E., 9/12; L. E., fingers at 5° divergence. Both discs very white, arteries very small. The sixth case was in a boy, aged seven, with a congenital, towering skull. R. E., 3/6; L. E., no perception of light. Brilliant white optic discs. The seventh case was in a boy, aged nine and a half, also with a congenital towering skull. R. E., 3/6, and marked concentric limitation of the field and color blindness; L. E., complete amniosis and divergence. Both discs white. In these cases the condition of the optic discs must be regarded as the result of an inflammatory action in the optic nerves, caused by an inflammation in the brain membranes, which itself was probably caused by the cranial deformity.

**Investigations into the Relations, Form, and Mode of Suspension of the Crystalline Lens in the Physiological State.**—J. E. Leopold and Masson ("Archives d'ophtalmologie," March-April, 1883) have made some extended observations upon the relations of the lens to the rest of the eyelid, and present their results in the shape of the following propositions:

1. The crystalline lens is elastic and biconvex. The radius of curvature of its anterior surface is longer than that of its posterior surface. The line of curvature of the two surfaces is straightened a little toward the equator by reason of the permanent traction exerted at this level by the fibers of the zonule.

2. The zonule is formed of a system of five independent fibers or small cords stretched between the pars ciliaris and the vitreous humor, from ora serrata to lens. These fibers are united to the pars ciliaris throughout their entire extent by a large number of filaments directed obliquely in two perpendicular directions. They glide freely over the vitreous humor, and merge anteriorly and posteriorly into a brush or bundle of fibers. The posterior fibrilla are merged into the vitreous humor, retina, and basal membrane of the pars ciliaris. The anterior fibrilla become merged with the lens. The zonule is kept permanently stretched by the ciliary processes, which press upon it like the fingers of a hand compressing a system of cords.

3. This tension of the zonule upon the vitreous humor flattens the lens by the eccentric tractions exerted at the level of the equator.

4. The ciliary body, by its contraction, draws the anterior part of the choroid forward and upward, and thus indirectly the posterior insertions of the zonule upward, and fixes the latter in its position upon the selerotic by a sort of corrugation of its tissue.

5. The fibrilla of the zonule are free and independent of each other. Hence traction is not always exercised uniformly upon all the points of the equator of the lens during the act of accommodation. This is the explanation offered for those cases in which observers, having placed before their eyes for a certain time cylindrical glasses, have observed in their eyes, after removal of the cylinders, an astigmatism in the opposite meridian.

6. The data previously acquired throw the limits of the posterior chamber of the aqueous humor much farther back than has hitherto been admitted. They show that this fluid may pass through the fibers of the zonule as far as the ora serrata. In fact, injections of soluble Prussian blue, or even of blue galingale, made directly and gently into the anterior chamber, penetrate the meshes of the zonule and reach the anterior origin of the nervous membrane.

**Axial Atrophy of the Optic Nerve Observed in Several Members of the Same Family.**—Keersmaeker ("Rec. d'ophtal.," April, 1883) cites five cases of this lesion. The first was in a young man, aged nineteen, with no specific antecedents and no alcoholism, but who was a masturbator. The father was an epileptic, and had been subject to manicidal delirium. The patient began to lose his sight three months before Keersmaeker saw him. The chromatoptometric field was narrowed to a very small eccentric spot, but the scotoma could not be accurately mapped out. There was an exaggerated persistence of accidental or complimentary images outside of the scotoma. The papilla were pale, with indistinct outlines, like the picture presented by inflammatory atrophy. The retinal arteries were narrowed and the veins engorged. Vision reduced to counting fingers at ten centimetres. The treatment consisted in the application every day of the galvonic current for five minutes for a period of two months, at the end of which time there was a marked im-

July 7, 1883.

provement in the vision. The four other patients were maternal uncles of the first patient, in all of whom the symptoms were about the same. They all had defects of articulation, hemming and hawing, and spluttering in their talk. The father of these uncles was subject to chronic alcoholism, with occasional attacks of maniacal delirium.

REPORT OF THE EIGHTH SERIES OF ONE HUNDRED CONSECUTIVE CATARACT EXTRACTIONS, WITH REMARKS.—Knapp's report ("Arch. of Ophth.," xii, 1) on another series of extraction of cataract is worth reading. His method of operating has undergone some alterations. The corneal section has gradually shifted from the peripheral-line of von Graefe into the circular-marginal of De Wecker. The excision of the iris, in cases where the capsule was healthy, has been less extensive than before. The opening of the capsule has been subjected to some experimental variation in its execution, of which, however, none has shown a superiority over the method described in former reports,—namely, the peripheral incision along the corneal section with a sharp needle-cystotome. The expansion of the lens was effected in all cases by external pressure, even if in complicated and hypermetropic cataracts the lens was intentionally expelled, together with its unbroken capsule. The removal of cortical remnants has been done less persistently than before. The utmost care was taken to prevent any foreign substance,—such as conjunctiva, blood, iris, capsule, and portions of lens tissue,—from remaining in the wound. Knapp thinks that extensive laceration of the capsule gives rise to reactive processes showing the clinical picture of a plastic, and sometimes of a supplicative inflammation, which starts from the capsule and implicates the iris and ciliary body. The remedy,—excision of the anterior capsule,—has proved in his hands a failure: it gave eleven per cent. of loss. The cause of this unfavorable result was probably the large exposure of the inner surface of the rest of the capsule and its adherent parts to the influence of the aqueous humor. Shreds of capsule may remain, folded or unfolded, between the lips of the corneal wound, preventing its thorough closure, and leading to different kinds and degrees of inflammation. The capsule is to be regarded as an element of danger in the extraction of cataract, and we should adopt that method of opening the capsule which makes it least liable to become the starting-point of irritative reaction. The disadvantage inherent to the peripheric incision of the capsule, the depression of the acuteness of vision in many cases by obstruction of the center of the pupil, can be satisfactorily met by a subsequent central division.

A CASE OF BICULAR HEMIANOPSIS SINISTER, WITH AN ACCOUNT OF THE AUTOPTY AND OF THE MICROSCOPICAL EXAMINATION.—Linnell ("Archiv. f. Augenheilkunde," xii, 2) reports an interesting case of this kind occurring in a man, aged sixty-three, whose vision began to fail in 1879. He had suffered for eight or nine years from neuralgia of the head and limbs, and for four years from paralysis agitans of the right side. The latter had slowly increased, and was accompanied by partial anesthesia. On the night of September 27th he was seized with a violent headache, accompanied by total blindness. This was followed by vertigo, nausea, and slowness of the pulse. These symptoms slowly subsided, and in twenty-four hours he began to recover his vision, which was never, however, completely restored. The neuralgia of the head and the vertigo continued, and his gait became halting and uncertain. His vision when first examined was 2/3, refraction emmetropic, and there was binocular left hemianopia. The pupils were contracted. The retinal arteries were contracted, but there was no other abnormal sign in the fundus. In April he had another attack of total blindness, from which he slowly improved to 2/4, but still the hemianopia remained. From this time on, however, the vision slowly diminished till he could only recognize large objects, and the right half of both optic discs became discolored. The vertigo and halting gait became worse, but there was no interference with his mental faculties. In June, 1881, a general tremor affected his entire body, from which he partially recovered, but in July he had another similar attack, accompanied by rigid contraction of the posterior cervical muscles, blindness, unconsciousness. Consciousness and a certain amount of vision returned in a few hours, and he slowly improved for six days; but he had involuntary evolutions, was very restless, and his face and neck became very turgid. All the symptoms then grew worse, he became comatose, and died on July 19, 1881. At the autopsy the dura mater was found so adherent to the calvarium that the latter could not be removed until the dura had been divided entirely. In the medullary substance of the right hemisphere there was found a large and firm coagulum, nearly circular, four cent. long and two and a half cent. thick. It lay close to the center of the hemisphere, and had not involved the cortex. The neighboring brain substance was softened for an extent of about two lines. The ventricular fluid was not perceptibly increased, but the velum and choroidal plexus were very vascular. The corpora quadrigemina were degenerated, and showed white softening. This condition was most marked on the left side, and extended laterally and forward, involved the corpora geniculata, the posterior and inferior parts of the left thalamus opticus, and the bottom of the fourth ventricle. A part of the left optic tract and the neighboring under-surface of the thalamus was examined microscopically, and found to contain small, glistening, spherical bodies, which were homogenous, and refracted light highly. They were partly isolated, partly in groups. The axis cylinders were first attacked by the morbid process. The degeneration resembled amyloid degeneration, but was not identical with it.

BAND-SHAPED OPACITY OF THE CORNEA (KERATITIS TROPICANA).—Magnus ("Klin. Monatsbl. f. Augenheilk.," Feb., 1888) has a short paper upon this subject in which he gives his views as to the pathogenesis of the disease. He lays special importance upon two facts: First, on the very high percentage (20 per cent.) of cases in which the disease attacks eyes which have already suffered in nutrition; and, secondly, that the corneal changes are almost always sure to appear in those parts which, from being uncovered by the lids, are more exposed to external influences. He regards the band shaped opacity as a specific disease of such eyes as have become partially or entirely blinded by some severe general disease. If we accept this view, and agree with Magnus in the trilling significance which the bandlike shape and the chalky deposits have in relation to the entire process, we may then agree to change the name "band- or girdle-shaped corneal opacity," or "calcareous film," for the more suitable one of "keratitis trophica."

(To be continued.)

Letters to the Editor.

AN ETHICAL INCIDENT.

New York, June 28, 1883.

To the Editor of the New York Medical Journal:

Sir: A few weeks since I was asked by some of my friends to meet a medical man in consultation who was described as being a very liberal homoeopathist. I naturally hesitated, as I was fearful that no argument of opinion might be reached, and, consequently, nothing accomplished. I, however, made an appointment, and, on meeting the medical man in question, I propounded some questions to him in order
to find whether we could meet on any common ground. To my great surprise, I found him to be a graduate of the University of the City of New York, a very intelligent man, and apparently well trained in the healing art.

We proceeded with the consultation; there was nothing peculiar or heterodox about his opinions, he responded promptly to my suggestions, everything went on smoothly, and the patient made a good recovery. In a subsequent conversation I taxed him with the question: Why did he call himself a homoeopathic physician? He answered that some years since a neighboring physician had recommended him to Dr. ——, who had been called the druggist of the profession, as having infringed the rules by using pulsatilla in his practice. This was not denied, the doctor stating that he regarded it as a good remedy, and that he intended to continue its use. For this offense his name was removed from our medical register. The doctor stated to me that he had felt that he must belong to some medical organization, so he joined a homoeopathic society. He at this juncture, however, affirmed, with almost an air of ferocity, "But I am none of your little-poll men!"

He expressed a disgust for some of his associates who were infinitesimalists, at the same time remarking that others, however, were good physicians in the best sense of the term, not having any dogmas, but who selected remedies just as we do—to wit: the one, in our knowledge and experience, as being the best adapted to a given case. He expressed a determination, which has been since acted upon, to resign from the society. I have told him that, if he desired it, I would make an effort to cause him to join our county society.

He proposes to do so after a little time. This has caused me to reflect upon the fact that there are evidently many real brethren in the homoeopathic ranks who are essentially with us, and who deserve to sit in our councils. Webster defines a physician as being "a person skilled in the art of healing." Do we doubt that many of our homoeopathic friends are otherwise than of this sort? Can we consistently assert that all of these men are quacks, impostors, and ignorant men? If we can not, then it surely follows that the attitude of the profession, as shown in the application of the old codes, violates the law of equity, certainly of charity, and is at variance with the teachings of any perfect code which regulates the conduct of one gentleman toward another.

Yours very sincerely,

Owen D. Pomeroy.

Miscellany.

The Behavior of the Uterus in Puerperal Eclampsia.—At a recent meeting of the Obstetrical Society of London, reported in the "British Medical Journal," Dr. Baxter Hicks remarked that the condition of the pregnant uterus during a series of epileptiform attacks had not been very closely observed, the general idea being that the uterus participated in the general excitement of the muscular system. Passages were quoted from different works on the subject, in illustration of this. The author then described two cases in which he had carefully noticed the action of the uterus. In each of them, coincidently with a convolution, a powerful and prolonged contraction of the uterus was observed. Between the convulsions, the uterine action was natural. He could not state the exact relationship in point of time between the convulsions and uterine contraction. He did not think that uterine contraction alone caused the convolution; for, in the most severe cases of tonic or clonic contraction of the uterus, convulsions did not occur. But there might in these cases be increased excitability. It had been suggested that increased force of pains might result from carbonic-acid intoxication due to the convulsions. He thought the immediate supervision of uterine contraction on the convulsive paroxysms, and the quietness of uterine action between them, told against this view. The presence of these contractions, together with the disturbance of the heart and vascular system, and the pupils, showed that the muscles of organic life were liberally affected during the paroxysms of eclampsia. These prolonged and powerful uterine contractions, as well as the carbonic-acid poisoning of the mother's blood, were a source of danger to the fetus; and, in its interest, speedy delivery was called for, if it could be effected without harm to the mother.

Dr. Robert Barnes did not doubt that the immediate cause of the uterine contraction was the convolution. Dr. Hicks's observations would lead him to reconsider the rule which he had adopted, to reject the "acouphetic force," from which he had seen disastrous results. With chloroform and improved operative measures, delivery might be effected early and safely; but the mother must be considered first. Dr. Gilly Hewitt thought the disturbances of the abdominal and renal circulation, caused by pressure of the gravid uterus on the renal veins, exercised a powerful influence in producing eclampsia. He had found benefit from diminishing this pressure by positional treatment and by unloading the bowels. Dr. Routh had seen marvelous benefit in puerperal convulsions from placing the patient on her belly and knees—a confirmation of Dr. Hewitt's views. Dr. Hicks did not recommend force in the extraction of the child. As to the effect of pressure, there was often no albumin in the urine before the first convulsive seizure.

Birth of an Unruptured Ovum at Term.—Dr. W. H. Bobbim writes to the "Lancet" as follows: "In May, Mrs. D., aged twenty-eight, a fine, well-made, fair woman, the mother of two children born at full periods and who had not had curettage, was taken in labor after a pregnancy of six months and a half. Anomalies were commenced about four hours previous to the birth of the child. When I arrived, the nurse told me the child was just expelled, lying under the bedclothes between the mother's legs. Upon raising the sheets, I found the whole contents of the large gravid uterus had been ejected. The placenta, membranes, waters, and the child were all intact; the mass was about the size of a large hat. The child was floundering about in the fluid, and struggling to be released. I raised the mass up by taking hold of the placenta, and found its total weight about nine pounds. The membranes were exceedingly tough, and, to release the child, I had to cut them with a pair of scissors, as I could not tear them open with my fingers. This is the only case [sic] I ever saw born in this fashion, where the child was viable, out of 7,000 cases I have attended, the nearest approach to it being one other case where the child was four months old in utero, the preparation of which I have in spirits. It is remarkable that the child was alive in membrana after being expelled in this way, and it lived for some days after. The wonder is that there was not considerable hemorrhage or inversion of the uterus. The mother stated the pains were not like those of labor, but a sudden rush out of the contents of the bowels." She had a good getting up. Had I been present at the birth, I should have ruptured the membranes, and thus prevented this singular and, as far as I know, unique labor, which may be classed as the rarest kind."

[Such cases are not extremely rare. Should any of our readers meet with one, we would caution him not to stop to weigh the mass before liberating the child.]

The Anastomosis of the Coronary Arteries.—In a recent number of the "Lancet" Mr. George C. Karop says: "The question of the anastomosis of the coronary arteries has been so often debated with variable results that, as Dr. West says in his very interesting communication, the textbooks show a want of uniformity, which, indeed, they could hardly help, unless they had all followed one authority. Ellis's 'Demonstrations,' eighth edition, says they descend toward the apex, but says nothing about their joining. Gray, fifth edition, says they do. Beatle, 'Practical Analysis,' says they anastomose freely; and Quain and Sharpey, on the authority of Hyrtl, one of the most successful injectors, says, or said, they do not. Some years ago, when junior demonstrator of anatomy at the Middlesex Hospital, I made some injections of the coronary arteries at the suggestion of Mr. Morris, and found that in some cases they anastomosed, and in others they did not, the latter being as two to one. I can only find actual notes of two cases, both children, one successful, the injection going in at the left and coming out at the right artery; the other unsuccessful, and where, on injecting both arteries, it was shown that no anastomosis existed. There is no record of the time after death when the experiments were made, and probably, as Dr. West points out, it may have something to do with it. His remarkable success will, of
MISCELLANY.

FOREIGN BODY IN THE URETHRA.—Dr. George Hunter, of Linlithgow, writes ("British Medical Journal"):

"An elderly gentleman, the subject of dysuria from prostatic enlargement, thought to aid the efforts of his bladder in its evacuation by insinuating the rounded head of his wife's veil-pin into the orifice of his urethra, and thereby opening up the passage. To his dismay, in its descent downward it slipped from his fingers, and the point of the pin disappeared from his sight. His attempts at removal only caused it to make its way farther back, and soon a discharge of blood from the meatus, and urgent but ineffectual attempts to pass urine, alarmed him, and induced him to send for me. On my arrival, I could just make out the head of the pin in the membranes urethra in front of the prostate, and could feel the point anterior to the serotum. To remove it, I fixed the head by pressing on it from behind forward, and then impaled the urethra against the point. By steady pressure and traction on the point as soon as it emerged from the under surface of the foreskin and several inches of the pin was pulled through, only the head remaining in the urethra. The point was then depressed toward the perineum, and, by compressing the flaccid penis in its long, tubinal axis, the round head of the pin was easily passed through the meatus, and the entire pin withdrawn. In its removal, not a drop of blood was lost, and the puncture remaining was not more severe than that resulting from the use of the ordinary hypodermic needle. Beyond enjoining rest and quiet for the first twelve hours, nothing further was prescribed, and my patient was next day in his usual health."

GOULIN APARINE AS A REMEDY FOR CHRONIC ULCERS.—Dr. F. J. B. Quinlan, Physician to St. Vincent's Hospital, Dublin ("British Medical Journal"), has treated cases of chronic ulcer with great success by means of ointments made from "cleavers" (Gaulium aparine). Respecting a very bad case of septic ulcer, Dr. Quinlan writes: "We had now come nearly to the end of April, and our failure in this case was complete. It appeared to me that now was the time to try the Galium aparine, which was beginning to peep out in all the hedgerows about Dublin. An ample supply for this and other less severe cases has since been kept up, and it has been used with the most marked success in the following manner. Grasping in the left hand a bundle of ten or twelve stalks, with a scissors held in the right hand, the bundle is cut into junks about half an inch long. These are thrown into a mortar, and pounded into a paste. This paste, which has an acid taste and slightly acid smell, is made up into a large poultice, applied to the ulcer, and covered with a bandage. It is renewed three times a day. Its action appears to be a slight steady stimulant, and powerful promoter of healthy granulation. Its effect in this most unhappy case was decisive and plain to all. Healthy action ensued, and has since steadily continued; and, after a month of treatment, both ulcers have been reduced to considerably less than half their original size. If this action continue, which I have no reason to doubt, the cure will be accomplished within a measurable and short period. The patient is in the ward, and any one can see the great amount of new dermatization which has been effected during the month." Dr. Quinlan was equally successful in several other cases. He continues: "A difficulty at once suggests itself as to its general employment: viz., that in winter and spring it is not to be had at all. It appears to me that this difficulty can be effectually met by the method of ensilage, by means of which green food for cattle has for the last few years been kept perfectly sweet and fresh by burying it in silos under the ground. This plan is generally known, but all particulars about it can be learned in the pamphlet of Mr. Thomas Christy, F. L. S. (Christy & Co., 155 Fleet Street, London, E.C.). In the case of the Galium, the process would consist of cutting the herb very fine, running it down by screw pressure into a glazed earthenware jar with an air-tight cover, and burying it in the ground. Thus secured from air, moisture, and heat, it would be likely to keep through the winter. One of my pupils, Mr. M. Pierce, has already laid it thus down, and will report the result to me. This plan, if successful, might be extended to other pharmaceutical herbs; for I have always had the idea that green herbs are more powerful than dried ones. Indeed, the late Mr. Donovan, of this city, used to maintain that, to make tincture of digitalis properly, the alcohol should be brought to where the foxglove was growing, and the live plant plunged into it."

DEATH FROM THE STING OF A BEE.—"From time to time," says the "Lancet," "we are startled by the news of a death following so closely on the sting of a bee that no reasonable doubt can be entertained of the causal relationship. The occurrence undoubtedly belongs to the chapter of accidents; and an explanation can only be obtained by considering those kinds of things which are of an exceptional nature. A sting of an ordinary bee on an ordinary man is perhaps never followed by anything more than a local reaction. To explain the lethal effect, therefore, we must suppose that the virus of the bee was of an unusual nature, either as a result of admixture from without or as a consequence of some disordered action of the physiological processes of the bee. If the fault do not lie in the insect, then we must turn to the other factors of the resultant effect. There can be no doubt that the injection of the venom directly into a vein is a very dangerous matter; and it is possible that this may be the accidental circumstance so necessary to afford a reasonable explanation. We learn from the 'Sheffield and Rotherham Independent' that a small farmer, aged fifty nine, while in good health and working in his garden, was stung in the eyelid by a bee; the signs of collapse rapidly set in, and the unfortunate man died within half an hour of the receipt of the sting. It is worthy of remark that the daughter stated that her father had been twice previously bitten by a bee, and was very ill on each occasion."

FILTH AND CONTAGION.—The relations of filth to diphtheria and kindred diseases are well illustrated in cases reported in the April monthly report of Dr. C. W. Chamberlin, secretary of the Connecticut State Board of Health. "Eight cases," he states, "were reported from Thompsonville. There was a small back yard containing the well and privy as usual, but, in addition, a deposit of filth a foot thick on a level, composed of putrefying vegetable waste, and a mongrel mass of nastiness. The ground sloped to the well and the deposit of filth came close to it. The windows of the bedrooms opened on this yard. The family that moved out had been afflicted with malignant scarlet fever, with several deaths. In quite a number of instances there have been from four to six cases in one family, or often all the members, and in all that have been carefully studied, some sufficient cause has been found. In one case there was a privy in the basement with a large trough, and but a few feet distant the cistern—the water supply for the family."

The dangers of contagion were also shown. Last winter there were some seventy cases of measles in Seymour, apparently spread from one person who attended a masked ball while sick with the disease. It is estimated that over a hundred cases were spread from that one center of infection; throughout the State there have been but few fatal cases.

Three cases of scarlet fever in one family were reported from Greenwich, where the disease commenced de novo—that is, no infection from a preceding case could be traced in the initial case. A case fatal in forty-eight hours after the attack of the disease was taken from a child convalescent from a case so mild that no physician had been consulted. The boy was playing on the sidewalk, and the mother of the ailing child, not knowing the danger of infection, or not believing it, called him in to play with her boy. In a week he came down with scarlet fever of the most malignant type, and died, as stated, in forty-eight hours.

One fatal case of small-pox was reported from paper rags. By prompt vaccination and isolation the spread of the disease was prevented. In Pocumtomock, a part of Windsor, there have been four cases, one fatal. The infection came from some bedding used by a small-pox patient a year or two ago, which had lain disused in the room. It was burned, but the man who burned it and a boy who was an outlooker came down with small-pox at the same time, although living quite a distance apart.

Throughout the State diseases of the respiratory organs maintained
the first rank upon the mortality lists. Dr. Chamberlain concludes his valuable report as follows: "The sanitary history of the mouth, like that of the year generally, thus far, has not been quite satisfactory. Exclusive of personal influence, the mortality is due to climatic changes and epidemic diseases. The latter, while not wholly under our control, can be almost wholly prevented. The field for sanitary effort is still a wide one."—Sanitary News.

The Optic行动 of Quinine.—Mr. Hartigan of Hong Kong, writes to the "British Medical Journal" as follows: "In three different cases I have had on several occasions to discontinue the use of quinine, because it brought on "tabor-pains," though the doses used were small, varying from three to five grains. In one of these, during a previous pregnancy, another medical man used quinine, and discontinued it for a similar reason. All three were in fair general health, suffering only from slight malarious fever, and had never abortion. One case has come under my notice in which abortion took place, without apparent cause, after a ten-grain dose of quinine. The patient was the mother of several children, had not previously aborted, was in good health, and took the quinine to cure facial neuralgia. I know of another case of abortion occurring under similar circumstances after quinine. This action of the drug is known to the Chinese, who take it (I am told with success) for the purpose of producing an abortion, following its use by copious draughts of hot tea. I have myself heard a Chinese 'amah' (i.e., female servant) recommend it. Quinine certainly, in some cases, increases the menstrual flow."

The State Board of Health of West Virginia will meet in semi-annual session at Martinsburg, Wednesday, July 11th.

The New Tariff on Drugs.—The new tariff, which went into effect at the beginning of this week, includes the following among other changes:

<table>
<thead>
<tr>
<th>Article</th>
<th>Old Rate</th>
<th>New Rate</th>
</tr>
</thead>
<tbody>
<tr>
<td>Refined glycerin</td>
<td>30 cent.</td>
<td>5c. a lb.</td>

The Baltimore Medical College.—According to the "Maryland Medical Journal," the following appointments at the Baltimore Medical College have lately been made: Dr. Charles G. Hill, Professor of Anatomy and Clinical Professor of Insanity and Nervous Diseases; Dr. R. H. P. Ellis, Professor of Medicine and Practice of Medicine; Dr. L. M. Eastman, Professor of Microscopy; Dr. J. H. Scrirb, Clinical Lecturer on Gynecology; Dr. J. J. E. Doerrsen, Clinical Lecturer on Diseases of the Eye and Ear; Dr. James G. Lithic, Clinical Lecturer on Obstetrics; Thomas H. Parramore, D. B. S., Clinical Lecturer on Oral Surgery; Dr. J. W. Kiley, Demonstrator of Anatomy. A prominent member of the legal profession will deliver a course of lectures on medical jurisprudence.

Resolutions on the Death of Dr. James L. Banks.—At the stated meeting of the New York Pathological Society, held June 27, 1883, the following preamble and resolutions were unanimously adopted.

Wesley M. Carpenter, Secretary.

Whereas, It has pleased God to remove from this world the soul of our late associate, James L. Banks, M.D.

Resolved, That we sympathize with his family in the great loss which they have sustained.

Resolved, That we cherish his memory as that of an intelligent and wise physician, a kind and genial companion, and a conscientious, upright, and honorable man.

Resolved, That a copy of these resolutions be forwarded to the family of our deceased associate, and that they be published in the medical journals of this city.

Army Intelligence.—Official List of Changes of Officers of the Medical Department, United States Army, from June 25, 1883, to June 30, 1883.—Smart, Charles, Major and Surgeon. Assigned to duty in the office of the Surgeon-General of the United States Army, and, in addition to his duties in the Surgeon-General's office, will continue to serve as a member of the National Board of Health. Par. 8, S. O. 147, A. G. O., June 27, 1883.——Blair, Victor, Captain and Assistant Surgeon. Assigned to duty as Post Surgeon at Fort Sisseton, D. T. Par. 1, S. O. 102, Department of Dakota, June 13, 1883.——Winne, Charles K., Captain and Assistant Surgeon. Assigned to duty as Post Surgeon at Fort Winfield Scott, California. Par. 1, S. O. 69, Department of California, June 19, 1883.——Worthington, James C., Captain and Assistant Surgeon. Assigned to duty at Cantonment on the Uncompahgre, Colorado, Par. 4, S. O. 128, Department of the Missouri, June 21, 1883.——Evans, Edward, First Lieutenant and Assistant Surgeon. Relieved from duty at Fort Cœur d'Alene, and assigned to duty as Post Surgeon at Fort Lopaw, Idaho. S. O. 81, Department of the Columbia, June 14, 1883.——Strong, Nanton, First Lieutenant and Assistant Surgeon. Relieved from operations of par. 2, S. O. 43, C. S., Department of the Plate, and assigned to duty with battalion infantry now on duty between Forts Thornborough and Bridger, Wyoming. Par. 2, S. O. 83, Department of the Plate, June 21, 1883.——To be assistant surgeons, with the rank of captain, after five years' service, in accordance with the act of June 25, 1874: assistant surgeon Victor Blair, June 6, 1883; assistant Surgeon William W. Gray, June 6, 1882; assistant Surgeon Louis Bredemus, June 6, 1883; assistant Surgeon Louis A. La Garde, June 6, 1883; assistant Surgeon Junius L. Powell, June 6, 1883. A. G. O., June 25, 1883.

Naval Intelligence.—Official List of Changes in the Medical Corps of the Navy for the week ending June 30, 1883—Surgeon E. Kershner, from the Navy Yard, New York, July 1st, and ordered to the receiving ship Colorado, New York.——Assistant Surgeon T. C. Craig, detached from the Colorado, July 1st, and ordered to the Naval Hospital, New York.——Assistant Surgeon J. H. Bryan, detached from the Naval Hospital, New York, and ordered to the Museum of Hygiene, Washington, D. C.——Passed Assistant Surgeon L. G. Henneberger, detached from the Museum of Hygiene, and ordered to the Navy Yard, New York.——Passed Assistant Surgeon J. Y. Bransford, detached from special duty at Washington, and ordered to temporary duty at Naval Academy, Annapolis.

Society Meetings for the Coming Week.—Tuesday, July 10th: Medical Society of the County of Chautauqua, N. Y. (Mayville—annual); Medical Society of the County of Chilton, N. Y. (Pattensburg—annual); Medical Society of the County of Jefferson, N. Y. (Watertown—semi-annual); Medical Society of the County of Madison, N. Y. (annual); Medical Society of the County of Ossipee, N. Y. (Uxter—annual); Medical Society of the County of Ontario, N. Y. (Canadigua—annual); Medical Society of the County of Rensselaer, N. Y.; Medical Society of the County of Schuyler, N. Y. (semi-annual); Medical Society of the County of Tioga, N. Y. (Owego); Medical Society of the County of Wayne, N. Y. (annual); Newark (N. J.) Medical Association (private); Jersey City Pathological Society; Trenton (N. J.) Medical Association (private). Wednesday, July 11th: Medical Society of the County of Cayuga, N. Y.; Medical Society of the County of Seneca, N. Y. (annual); Tri-States Medical Association (Port Jarvis, N. Y.). Thursday, July 12th: Medical Society of the County of Fulton, N. Y. (Johnstown—semi-annual). Friday, July 13th: Medical Society of the Town of Sangerties, N. Y.
A CLINICAL LECTURE ON ANATOMICAL LESIONS OF THE FEMALE PERINEUM.
DELIVERED AT THE LONG ISLAND COLLEGE HOSPITAL.
BY A. J. C. SKENE, M.D.,
PROFESSOR OF GYNECOLOGY: VISITING PHYSICIAN TO THE HOSPITAL.

Gentlemen: I desire to call your attention to the subject of lacerations of the female perineum, and the results which may occur if appropriate treatment be neglected for the restoration of its function.

The various degrees of this laceration are clearly stated in our modern text-books, consisting as they do of three degrees, viz:

1. Superficial rupture of the fourchette and perineum, not involving the sphincters.
2. The rupture extending to the sphincter ani.
3. Rupture through the sphincter ani, which may involve the recto-vaginal septum.

There are some lesions, however, the final results of which have not been discussed in our literature at the present day, and to which I would specially direct your attention, while discussing the subject of perineal lacerations, in those cases who may present themselves at our clinic to-day.

The first to which I shall direct your attention is the separation of the perineal muscles at their junction in the median line, without an accompanying laceration of the vaginal mucous membrane or the integument of the perineum. The appearance of the parts, viewed externally, gives no evidence of the lesion, the distance from the posterior commissure to the anus being perfectly normal. On separating the labia, however, or on introducing the speculum, the posterior vaginal wall also appears to be uninjured, but, upon examination by the touch, the deeper structures of the perineal body are observed to be absent. In passing the finger into the vagina and making pressure backward and downward, the mucous membrane of the lower portion of the vagina can be brought directly in contact with the integument below.

A similar condition of things I have quite frequently observed in patients upon whom the operation of perineorrhaphy had been performed, with the result of obtaining union of the integument and mucous membrane without restoring the perineal body.

In this condition of separation of the deeper structures of the perineum, the effect is precisely the same as in those cases where the mucous membrane and integument have also been lacerated, as they ordinarily are. The sustaining and supporting power of the perineum is entirely lost. The integument and mucous membrane are relaxed, and hence permit eversion of the vaginal walls, and subsequently prolapsus of the uterus and bladder. In one case which I have seen—a lady of over sixty years of age—it appeared that a portion, at least, of the sphincter-ani muscle had been ruptured; at any rate, the patient had very imperfect control of the rectum, and still, on superficial examination, the perineum appeared to be complete, so far as skin and mucous membrane were concerned. I am inclined to think that what has been described by Matthews Duncan and others as functional imperfection of the perineum has really been this subcutaneous laceration of the central structures of the perineum.

Regarding the cause of this condition, I am inclined to believe that it is the same as that in ordinary lacerations— namely, parturition.

I accept this view of the causation because in all the cases I have seen there has been a preceding parturition. In these cases it would seem that the elasticity of the muscular structures was less than that of the integument and mucous membrane, so that, while the former gave way when put upon the stretch, the latter came out uninjured.

Regarding the treatment of this condition, I am not quite satisfied that anything of value can be done for it. If the case is recent and the perineal muscles have not become atrophied, then I believe it would be good practice to divide the integument and mucous membrane, and, if need be, removing the superabundant portions of these latter, bring the deeper parts together—if possible, with sutures, as in the ordinary operation for restoring the perineum. The second condition is more rare than the one just described, and consists in atrophy of the perineal muscles, including the levator-ani muscle.

A typical case of this affection came under my observation in 1879. She was forty-four years of age, married, and had had several children. She had prolapsus of the vaginal walls, and a slight prolapsus of the uterus. These conditions were quite apparent on superficial examination; but a more careful study of the case revealed the following: The distance from the posterior commissure of the vulva to the anus was normal; but, upon grasping the perineum, with the index finger in the vagina and the thumb upon the outer surface, no intervening muscular tissue could be detected. The posterior vaginal wall could be brought in direct contact with the integument. On the most careful digital examination by the vagina, I failed to detect any evidence of muscular tissue. Running from the center below to the left sacro-iliac junction, the rectum could be distinctly felt firmly contracted, feeling through the vaginal wall like a cord the thickness of the finger.

This was demonstrated by passing a catheter into the rectum, showing that there was firm contraction of its muscular walls, and yet its dilatability remained normal, as evidenced by the fact that the bowels moved easily and freely. Although there was a marked prolapsus of the posterior vaginal wall, there was not the slightest rectocele. When the patient assumed the erect position, the anus and perineum bulged downward; this was also apparent when the patient was in Sims's position, with the knees drawn up. The anus projected downward until it came nearly on a line with the lower portion of the nates. In fact, the descent of the remains of the perineum and anus presented an appearance not unlike that which is observed during labor, when the fetoal head begins to push these parts downward.
It was clearly evident to me that all the muscles which form
the floor of the pelvis had become entirely atrophied. This
view was confirmed by the fact that all my efforts to restore
the tonicity of the parts failed, and the only relief afforded
was by the use of a perineal pad. In seeking for the cause
of this condition, I have been unable to find anything deﬁ-
ten. It is just possible that this patient suffered a subcu-
taneous separation of the perineal muscles during one of her
conﬁnements, and that long disuse of the muscles after
this separation caused fatty degeneration. This is a rational
explanation of the atrophy of the perineal muscles, but not
of that of the levator ani.

Perhaps the levator-ani muscle was congenitally deﬁc-
tive; or, again, it may be that the separation of the other
perineal muscles imposed an unusual strain on the levator
ani, which caused it to become atrophied. All this, how-
ever, is speculation in relation to the genesis of these pecu-
liar aﬀections of the female perineum. The point of most
importance at present is, to know that such injuries to the
perineum do occur.

In regard to the treatment of those cases, it is clearly
evident to my mind that the only possible way of repairing
the damage is to operate as soon after the injury as involu-
tion will allow. Because the longer the separated muscles are
functionally inactive, the more certainly will they undergo
degeneration and become permanently useless.

There is still another important fact connected with in-
juries to the perineum to which I have already called atten-
tion—namely, the atrophy of the muscles which takes place
in laceration of long standing. In such cases perineorrhag-
phy, as ordinarily done, gives very poor results. Good union
of skin and mucous membrane may be obtained, so that
the operation may appear to be a success, but the wasted
muscles can no longer perform their function, and the opera-
tion is practically a failure. Integument, mucous membrane,
adipose and areolar tissue do not constitute a perineum
capable of supporting the pelvic viscera.

Case 1.—Laceration of the perineum in the ﬁrst degree.
Patient under ether.

The patient now before you came into the hospital last
night suffering from simple laceration of the perineum of the
ﬁrst degree, involving the sphincter vagina and part of the
perineal body. This condition is very deceptive, look-
ing as though there was more perineum than there really is.

The amount of the perineal body is, however, readily
shown by passing a sound into the rectum and measuring the
perineum above; you can here distinctly estimate the
extent of the laceration.

I will now show you the several steps in the operation,
the ﬁrst being to vivify the tissues. This we do with the
scissors, with which you can make the parts to be united
perfectly smooth. But to do so you must have the central
portion put upon the stretch by the aid of your assistants.
By adopting this means you can trim your surfaces and
edges perfectly straight.

You will observe that my ﬁrst suture I insert at the
anal portion of the laceration, passing each subsequent su-
ture upward until I have now applied three sutures. The
fourth suture I specially call your attention to, and its man-
ner of insertion. I ﬁrst enter it through the integument
upon one side, then carefully carry it through the lateral
half of the body of the perineum, and then sweep the
needle round through the central portion until I reach the
extreme limit of the viviﬁed tissues high up in the vagina.

By this means I completely close the upper portion of the
wound and leave no room for the vaginal secretions to enter.

You have also noticed that during all this time my assistant
has carefully sponged away all blood oozing from the parts,
to let me see what I was doing, and also to insure, as far as
practicable, a union by ﬁrst intention by leaving the parts
clean. I have also inserted a ﬁfth suture, simply passing
through the tegumentary borders of the wound in order to
still further guard against secretions entering the wound.

The ligatures having now all been tightened, the patient
will be placed in the ward, and the bowels kept gently
open, in order to prevent any strain upon the parts until
they unite. The laceration is not a great one, and only
calls for surgical treatment to prevent a prolapsus of the
vaginal walls which was being developed. This is the sim-
plest form of laceration, and hence the operation for its
restoration is easy and simple. The time required to oper-
ate was only twenty minutes, and yet you observed that no
undue haste was made. (Patient presented to the class two
weeks after, and the result proved to be good.)

Case II.—This case is one of Dr. Stewart's, and I will,
therefore, request him to give you a brief history of her case.

History as given by Dr. Stewart.—This patient was con-
fined in the hospital, and sustained a laceration of the peri-
neum extending into the rectum. I performed the imme-
diate operation, putting in ﬁve or six sutures. The opera-
tion promised very well, but at the end of four or ﬁve days
there commenced a purulent discharge; injections were
carefully used, and all the procedures in such cases were
gone through with, but without arresting the discharge en-
tirely. We recognized that we had at least partial union
when we removed the stitches. This woman is brought
here to-day to show how, even under most unfavorable cir-
cumstances, we may get union by primary operation for
restoration of the perineum.

In this case there really is more perineum than is ap-
parent. In fact, we ﬁnd a tolerably good perineum, which
result is quite remarkable under the circumstances, to say
the least of it. The doctor has obtained as good a result
as was seen in the case which I showed you—the one that
was operated upon years after the injury. I have, however,
perhaps a little more perineum in my case. I do not be-
lieve that either of us obtained perfect union of the ends
of the sphincter muscles, but we secured the next best
thing—union through the middle of considerable scar
tissue, so that the sphincter can perform its function by
contracting toward the perineum as the ﬁxed point. So
you see that the anus is drawn forward because of this ﬁxed
point of scar tissue; she, however, has perfect control of the
rectum. This is proved by the testimony of the patient and
the fact that, as I introduce my ﬁnger into the anus, the
muscle contracts toward the ﬁxed point ﬁrmly enough for
all practical purposes, and the patient will be able to get
along well enough.
SKENE: LECTURE ON LESIONS OF THE FEMALE PERINEUM.

These cases are called perfect results; they are, perhaps, good enough, and we are glad to get them, but yet they are not the most perfect results attainable. This case gives us the opportunity to call attention to the importance of the primary operation, as it is called, in laceration of the perineum. There has been some discussion about that of late years, some claiming that, if you simply bring the parts together without sutures, you may secure union, and that you are not more likely to obtain it if you introduce sutures; for this reason some have advocated this mode of treatment. Others, again, and I think that the great majority of gynaecologists of the present day, favor the primary operation. By that I mean the immediate operation, which is performed as soon as you have removed the placenta, and the uterus has contracted. Do not leave your case and go home, and then return the next day to perform the operation, because then the parts are not in a condition to unite by first intention; if you disturb them by manipulation, you then, also, utterly spoil the possibility of union without sutures. If you are careful to remove all blood-clots and bring the parts together, and bandaging the limbs to secure perfect rest, you may get union if there is not much subsequent haemorrhage. Union has frequently occurred under those circumstances. So, if you propose to trust to nature, you had better adopt this plan; but do not change your mind and use sutures the following day, because that would almost insure failure.

I am a great advocate for the primary operation, and in all cases of any importance I believe that it is always well to introduce sutures, if you do it properly, putting in your stitches just tight enough to keep the parts in apposition.

I remember a case which made a profound impression upon me. I was sent for by a medical gentleman in the case of a primipara, and, on examination, I found a breech presentation, with the os partially dilated. I suggested that he might wait awhile. The patient had a masculine pelvis, and I thought it would be advisable to secure perfect dilatation before attempting delivery. I heard no more of the case until the following morning at about the same hour, when her physician again sent for me. I then found, upon examination, the os fully dilated, the labia edematous, and the nates of the child presenting at the vulva and extremely dark in color. The physician told me that the os dilated soon after I left on the day previous, the breech at once settling down in the pelvis, where it remained. We proceeded at once to remove the child, and succeeded in extracting the feet and bringing down one arm, and, while I was bringing down the other arm, the doctor whispered to me that they were very anxious for the life of the child. At this moment the little fellow moved one of his feet, much to my surprise. I then extracted rapidly, and succeeded in obtaining a living child. I, however, tore the perineum through to the rectum, the parts being in that extremely edematous condition they had lost their elasticity.

This patient began the process of parturition late in life, and this long-continued pressure (in all three days) rendered the parts so edematous that they gave way, and I made the biggest perineal laceration I have ever made in my life. I immediately brought the parts together with sutures, though I had very little hopes of their union in such a condition, as they were so enormously swollen. However, we brought them together, and I heard no more of the patient for twenty-four hours, when I was again sent for by her physician, he informing me that he had failed to pass the catheter. I separated the labia, and found a dark, sloughing mass, which rendered it quite difficult to tell where the meatus was. I, however, made gentle pressure at the point where I supposed it should be, and, without further difficulty, passed the catheter and evacuated the bladder. The doctor passed the catheter once or twice afterward, when all at once the patient urinated of her own accord, believing it was all right; but, upon a careful examination, it was discovered she had a vesicle fistula.

I saw her a week after, when the labia and thighs were covered with an ill-conditioned-looking diphtheritic exudate. It was a horrible condition to be in, the lochial discharge flowing over these surfaces, and the urine dribbling away. She, however, recovered from this, and you will hardly believe me when I tell you that the vesicle fistula closed of its own accord—a thing which does sometimes occur. When we removed the stitches from the perineum, it was found that she had a perfectly good perineum, and a good sphincter; I have never yet seen a better.

That case made a profound impression upon me, for, if we can get union occasionally in such cases, we can have good hope for success in simpler ones. I would say, always perform the primary operation when the condition of the patient will permit, for, if you do not get union, you cannot operate subsequently. If you get just a little union, it is some gain. There is really every argument in support of the immediate operation. You have everything to gain and nothing to lose.

The child in this case was a splendid-looking little fellow after the ecchymosis disappeared; but, after all our trouble in the case, he did not survive. His bowels positively refused to act. Upon an examination being made, it was discovered that the colon was nothing but an impervious cord.

CASE III.—You doubtless remember the patient whose perineum I endeavored to restore a week since; she had suffered long from marked constipation. I at that time stated that I should order the bowels to be moved freely each day after the operation, and adopting the new order of treatment, to which I call your attention—viz., to keep the bowels free in place of confining them, as we used to do after restoring the perineum. The day following the operation a full dose of Rochelle salts was administered, and the following morning it was repeated; when it was time for this to have acted, an enema of ox-gall with soap and water was given. On the following day castor-oil was given, followed by another enema of ox-gall with oil; this, however, failed to secure the results anticipated, and was therefore abandoned and the following prescription substituted: One ounce of senna leaves put into a quart of water and boiled down to a pint, then adding an ounce of Rochelle salts; two ounces of this preparation was given to the patient every thirty minutes; in all, five doses were given, which secured
copious and easy evacuations; and this morning it was repeated with a like effect.

I mention this case to show you how extremely difficult it is at times to move the bowels in women who are habitually constipated. This patient's bowels were moved usually but once in two or three weeks. This seems incredible, and for a long time I used to doubt this when told so by the patient, if she retained a fair degree of health; I, however, fully believe it now, having seen many patients like this one. I am indebted to Dr. Palmer for the prescription last used in this case. I was telling him of my difficulty in some of these obstinate cases, and he informed me he had encountered the like difficulty, and had found that this preparation answered admirably. I therefore adopted it in this case, and effected the most satisfactory results. The movement of the bowels has done no harm, so far as we know, to the perineum, although the laceration involved the sphincter ani. I always feel a sense of safety when the bowels move without causing any bleeding, for, if the newly formed tissues were separated, it would occasion more or less hemorrhage. What the final result may be here I do not know, I, however, feel quite confident of securing a good result.

This case fully illustrates how we may be disappointed in the action of our cathartics, although the patient here had taken sufficient to move a whole company of soldiers, but upon her it produced no effect.

Hemorrhage in these operations is often a source of difficulty and delay to the operator, but, worse than that, it is sometimes the cause of failure. In the vast majority of surgical operations, all that is required of the surgeon is to arrest the hemorrhage in order to secure a good result; but in the operations in question, if styptics have to be used, the operation fails. Cases differ so very much in regard to hemorrhage that I have given much thought as to the predisposing causes of this bleeding tendency, so marked in some patients. The hemorrhagic diathesis in its most typical form is generally found in men, but a less marked hemorrhagic tendency is common to many women, who are very unpleasant subjects to operate upon. During the past few years it has been my misfortune to meet quite a number of cases in which the bleeding tendency was noticeable. The cause of this in most of them, I think, was due to impaired general health, due to exhausting conditions of life rather than to any congenital imperfection of the blood itself. Another very important element I found to be mechanical interruption of the circulation, the pelvic organs becoming congested from retardation of the portal circulation, induced by hepatic disorders, sedentary habits, tight lacing, and so forth. The products of former pelvic inflammations, such as pelvic cellulitis, also tend to maintain a hyperemic state of the pelvic organs; this we often find long after all evidence of active inflammation has subsided.

The condition, also, of the uterus and perineum is often favorable for bleeding; the well-defined vascularity which exists in conditions such as imperfect involution insures hemorrhage in all operations undertaken during such unfavorable states. The possible hemorrhage from such causes can be avoided by the proper selection and preparation of your cases before operating. This fact is well known to all gynecologists, but I mention it now because others less familiar with the diseases of women are liable to neglect this very important matter. I know this to be true from having patients sent into hospitals for operations which they are not at all prepared to undergo. It also happens occasionally that I am called to operate in private practice at a time when I can only suggest a course of preparatory treatment.

The rule which should be followed in this matter is to secure the best possible state of the general health of the patient, and to reduce all hyperemic states of the pelvic organs as far as possible. This is generally possible to a great extent, because the object of plastic operations is to restore the organs to their original form and structure, differing in this regard from many other operations in surgery which have for their object the removal of diseased parts.

In carrying out this plan of treatment, however, there is one difficulty encountered in practice: when the patients are ill and suffering, they will gladly accept an operation which promises them relief, but, when they are relieved from pain and have gained in health, they hesitate about undergoing any surgical treatment which is designed to keep them from suffering in the future. This, however, does not persuade the surgeon from doing otherwise than that which is best. There are cases—fortunately very few—who have the hemorrhagic diathesis sufficiently marked to debar them from operations, and it is doubtful if any preparatory treatment will change this constitutional peculiarity. Such subjects should be let alone: to operate in these cases is dangerous, and almost always ends in failure. I have had three such cases in the past five years; two of them were operated upon before discovering their peculiarity, the results being depletion of the patients without any benefit from the operation, and the development of extreme caution on the part of the operator in selecting cases in future. The third case was diagnosed earlier, and I declined to operate.

These few remarks regarding the predisposition to hemorrhage, and the best means of overcoming the same, bring me to the point of my subject, and to which I desire to call your special attention—viz., the management of bleeding in plastic operations upon the perineum and cervix uteri.

In restoring the perineum, the mucous membrane only should be removed; if the deeper structures are wounded, the hemorrhage will be much greater. All sear tissue must also be removed; but, if care is taken to separate it from the normal tissue, large vessels may be avoided. By observing these rules, troublesome hemorrhage from the lower portion of the denuded surfaces will be avoided. Occasionally, in deep lacerations, a small artery on each side may require to be ligated; the chief arterial bleeding, however, comes from the upper portion, the small vessels coming apparently from above downward in the areolar tissue, between the rectum and vagina. These sometimes bleed quite freely, and they are not arrested by tightening the sutures which control the hemorrhage at points lower down. Such vessels I control by passing a needle through the vaginal mucous membrane above the denuded surfaces, and thus carry
prepare the silk ligature and make it aseptic. I have in my possession a piece of silk ligature which I left in the cervix uteri for more than a year.

The woman became pregnant. Soon after, I restored the cervix, and she came to me six weeks after her confinement, and I then found one of my sutures; the length of time which it had remained in the tissues was one year, two months, and twenty days; this was several years ago, and the suture is good yet. This shows that you can submit the silk to any test, and it will do less damage than the silver wire. Had I used the silver wire in that case and allowed it to remain, the patient would probably have returned to me long before.

Case V.—This woman has borne three children, the youngest being between three and four months old, and weighing at the time of birth fifteen pounds.

Now, here you will observe, as a result of this enormous distension of the parts necessary to give birth to such a child, a laceration of the perineum has occurred. There is really very little laceration apparent now; it, however, extended originally to the sphincter ani muscle, for I here see, a little to one side, a scar which extends down to that point; and I think that some of the fibers of the muscle have been lacerated, as there is a want of elasticity at this portion, and I also find a hemorrhoidal condition at the termination of the rectum.

This gives us an illustration of a laceration of the perineum which has in part been repaired by natural or primary union, and very nicely too. There is not much scar tissue; the union has been prompt and good so far as it went. We obtain this result sometimes in lacerations—i.e., union without the aid of sutures.

We are liable to be deceived about the extent of the laceration at the time it occurs. The parts being hypertrophied, and sometimes swollen, just after labor, the laceration appears enormous, giving a feeling to the touch as if the perineum were lacerated entirely through into the rectum; and yet, upon a careful examination, you may find it to be a laceration in the second degree only.

Now, when the union takes place promptly, as it did in this case, you get a good perineum; but, when you get a union by granulation, which gives a large amount of scar tissue, it is apt to cause trouble, as these scars are often extremely painful. The little bit of scar tissue which you get when the union is prompt is harmless; but, when you get a mass of scar tissue as thick as your finger, with nerve-fibers caught up in this tissue, it gives rise to the most severe pain and suffering, and impedes locomotion.

I had a case of this kind last winter. The patient had a difficult labor, forceps being used in the delivery, and there was a marked laceration of the perineum; some effort had been made to restore it, but it was a long time healing, and then only partial union was secured through a large mass of intervening scar tissue. When she had risen from her bed and attempted to walk, she was seized with violent pains in the region of the perineum; this occurred on every subsequent attempt to walk, and finally she gave up the idea of walking. Some time after, she came under the treatment of a good practitioner, and I was called in consul-
tion, the case having previously been diagnosed as separation of the symphysis pubis. I examined her carefully, but could find no satisfactory evidence of separation of the symphysis at that time, but yet it was impossible for her to walk. I found a large quantity of scar tissue in the perineum, a large mass in the center so exquisitely tender that if you touched it the patient suffered agony. I immediately advised the removal of this scar tissue, and the operation was afterward performed, resulting in the restoration of a good perineum without any tenderness; and she is now walking around and is perfectly comfortable.

While she was under the anæsthetic, I was enabled to satisfy myself beyond doubt that there was no separation of the symphysis pubis, and I do not believe there ever had been, as the result of the removal of this scar tissue tended to prove, her difficulty of locomotion and this severe pain upon each attempt to walk being due to the sensitive scar tissue. You see, then, that in laceration of the perineum the continuity may be restored by intervening scar tissue, and yet the result may be very unsatisfactory. When such painful and tender scars are found, the only treatment is to remove the nerve-tissue, bring the parts together with sutures, and obtain mediate union of the normal tissues.

**Original Communications.**

**DISLOCATION OF THE STE R NAL END OF THE CLAVICLE WITH DISLOCATION OF THE FIRST AND SECOND COSTAL CARTILAGES.**

**ALSO A CASE OF DISLOCATION OF THE CARTILAGES OF THE FOURTH, FIFTH, AND SIXTH RIBS.**

**BY ALBERT N. BLODGETT, M. D., BOSTON.**

**CASE I.**—Fred. C. G., of St. John, New Brunswick, aged eighteen years, consulted me June 7, 1869, on account of obscure symptoms located in the chest. Family history is free from all indication of hereditary disease, and the patient is one of several strong and healthy children, of whom three are personally known to me.

Eleven months ago, when sixteen and a half years of age, this young man was practicing in a gymnasium, and, while exercising upon the parallel horizontal bars, he by mistake made a "dip," in which the shoulders and body sunk to a lower level than the bars upon which he supported the entire weight of his body by his hands. A great and unexpected strain was at once brought upon all the cervical, thoracic, and scapular muscles. There was a sudden sharp pain in the right side of the sternum; the patient "felt something give way"; he could execute no movement with the right hand or arm without greatly increasing the thoracic distress, and, on going home, was unable to remove his clothes without help. Mr. MacFarland, of Portland, New Brunswick, saw the patient four hours subsequent to the injury, and found, I am told, "a separation of some of the ribs." A firm bandage with a padding of cotton was applied, which the patient wore for six months, when recovery was considered complete. Since the time of removing the bandage (now one year) there has been no pain in the part, but the patient often experiences soreness and an undefined tenderness in the right thoracic region. During the past six months the patient has suffered from repeated attacks of hemoptysis, occur-
ring at intervals of two to six weeks, always of moderate amount, the largest quantity of blood at any one time being esti-

mated by the patient at less than one ounce. This was accom-
panied by progressive though gradual loss of flesh and a certain degree of general weakness. Has never had a persistent or troublesome cough nor expectoration, but complains of a feeling of lassitude and general disability, for which he seeks advice. 

Upon the chest being bared, the observer is at once aware of a striking degree of asymmetry in the anterior wall of the thorax. The entire upper portion is quite flat, and the outlines of the ribs on both sides very distinct. In the lower front of the chest a notable prominence is perceived, commencing 1 ctm. to the right of a line drawn from the middle of the supra-ternal notch to the center of the ensiform appendix. This prominence occupies the seat of attachment of the cartilages of the fourth, fifth, and sixth true ribs to the sternum. The protrusion is sharply defined at the sternal border, and follows a nearly straight line from above downward.

From the plane of the back to the anterior surface of the chest-wall over the fourth, fifth, and sixth costal cartilages on the left side, the distance is 14.4 ctm.; from the same plane to the anterior surface of the chest-wall over the corresponding cartilages of the right side, the distance is 15.8 ctm., showing a forward displacement of the cartilages of the right side 1.4 ctm. That this is a luxation of the cartilages, and not properly a fracture, is rendered highly probable, if not absolutely proved, by the fact that the patient’s body is emaciated to such a degree that the outlines of the cartilages and the location of their attach-

ment to the sternum can be both plainly seen and felt. Added to this is the important factor found in the absence of the subject, the articulation being eminently a ligamentous union without ossification, and the cartilages themselves being highly elastic, and not liable to a fracture in their continuity. The line of separation is also much nearer the middle of the sternum than it could be in a fracture of the cartilages, and is a direct continuation of the line of junction of the remaining costal cartilages on the same side.

The cartilages of the fourth and fifth ribs are firmly united for three centimetres outward from their dislocated ends, by means of a permanent callusity which renders them immovable one from the other. There is no such adhesion of the sixth rib to either of its neighbors. The parts are fixed in their present position, there is no pain or soreness about the chest which can be attributed to the dislocation, and the patient considers himself well so far as this injury is concerned. There is no impair-

ment of function in the body or limbs, but the movements of the right arm seem to be executed less vigorously than those of the left. There is no indication of rachitis or of any other general disease of the osseous or cartilaginous structures of the body, and the patient’s general appearance is in no way striking except as mentioned above.

Alfred Poland, in Holmes’s “System of Surgery,” vol. ii, p. 561, in speaking of the fractures of the sterno-costal cartilages, says that this lesion, uncomplicated with other injuries, is exceedingly rare, although recorded as early as 1668 by Zwinger, who found this fracture when examining a dead body. Malgaigne, in his work on fractures, had only seen three cases. At the Hôtel Dieu only one case occurred in 2,928 cases of fracture generally. The uncertainty whether, at the age of forty-five years, the lesion of continuity between the sternum and the cartilages of the first ribs is of the nature of fracture or dislocation, may make an accurate diagnosis of this particular injury impossible, obscured in addition as it is from the fact that con-

siderable time had elapsed since the accident before the case came under my observation, during which time the nature of the injury had been wholly unrecognized by the attending physician. It is practically of little importance, however, whether the displacement in this patient was due to fracture or traumatic dislocation, and the observations upon either of these lesions will apply to the case under discussion.

Dr. Carl Emmert states that the luxations of the costal cartilages are not to be regarded as dislocations, but that they are in reality fractures, and that the separations of the cartilages of the false ribs from their attachments is also fracture, and not properly luxation. The same authority, in again speaking of dislocation of the costal cartilages, pronounces it very rare, and states that this accident is always associated with other severe injuries. Mr. Poland further states (p. 566) that the luxation in chondro-ternal dislocation is accompanied with prominence of the carti-

lages and pain, and may be attended by severe symptoms, febrile excitement, and spitting of blood. He records five cases, in two of which the cause of the injury is not given; in one it was caused by violent exercise with dumb-bells, particularly in extension of the arm. The second case, in a woman, was caused by a fall during intoxication, and the third, affecting a baker, was the consequence of constant ac-

tivity of the pectoral muscles in kneading bread. Of these five patients, three are reported “cured,” and two are classed as “uncertain.” In one of those who recovered, the in-

jury consisted in the luxation of one of the costal carti-

lages forward into the sternum, which was replaced and held in position by bandages. In another, the fourth left cartilage was dislocated. Inconstituted, the cartilages of the fourth, fifth, and sixth true ribs were dislocated forward.

Professor Gross has recorded a case of dislocation of the costal cartilages in a man of sixty, who fell ten feet, the left shoulder and chest receiving the blow. Immediately there were severe dyspnea and a grating in the side with each movement of respiration. Examination discovered a dislo-

cation of the last three costal cartilages from the sternum. Professor Gross adds: “Whatever form these costal carti-
lages may assume, their existence necessarily implies the infliction of severe injury, which can not fail to tell badly upon the soft parts, both externally and within the chest, and to be followed, when not immediately fatal, by violent infiammation.”

M. Demarquay, in the “Dictionnaire de médecine et de chirurgie pratiques,” when treating of luxation of the ribs, writes as follows: “Although the luxation of ribs at their vertebral ends constitutes a rare affection, it appears, accord-
ing to all known observations, that the sterno-chondral dislo-
cation has been even less frequently observed. Four care-

fully authenticated cases form the total list of these inju-

ries. Chausier reports the first case, in which the eighth rib on the right side and the seventh on the left side were dislocated in the same individual. The seat of the injury on each side was occupied by a pulmonary hernia. Charles Bell reports the details of an interesting case in which “most of the ribs” were dislocated upon their cartilages, the individual having been crushed between a post and a
carriage. The two remaining cases are reported by Bouisson and Kimpe, in the first of which the fourth rib on the right side, and in the second the fifth rib on the right side, were the site of dislocation. The most constant symptom attending this luxation is the prominence of the costal end of a rib in advance of the corresponding cartilage; and wherever this dislocation has been observed it has been the result of a violent shock upon the sternal ribs, or close to the anterior extremity of a single rib. It is, however, not always possible to determine that the injury consists of a dislocation.

Bouisson proved without doubt that in his case the injury was not a fracture of the rib, but nothing proves that it may not have been a case of simple fracture of the cartilage. The patient of Chassier experienced crepitation with each effort of coughing.

The patient of Kimpe alone seems to have presented an undoubted dislocation, as the separated cartilage measured the same as its fellows. One can easily see that it is possible to cast a doubt upon the existence of these luxations when it is remembered that the costal cartilages ends by direct fusion with the rib, and that it is not a true articulation, but a continuity of tissues. From a clinical point of view, this difference is entirely of secondary importance, so that whether the injury be a luxation at the point of junction of the cartilage with the rib, or a fracture in the immediate vicinity, the treatment varies but little, and the gravity of the case is not modified.

The same author adds: That which has been said upon the subject of chondro-costal dislocation applies also to the dislocation of the cartilages upon the sternum. Unfortunately, known cases of this injury are still very rare, and the history of this affection is as yet incomplete.

In the case reported by Ravaton, Manzotti, Monteggia, and Charles Bell, the injury was uniformly produced by a crushing inward of the sternum. Ravaton's case occurred in a person seventy-two years of age, who suffered a dislocation of the fourth left cartilage from a drunken fall. Charles Bell's case was that of a young man who suddenly experienced a severe pain of a tearing character while forcibly throwing the arm backward, and was found to have dislocated one of the costal cartilages. Whatever may be the cause of the injury, it is generally the cartilages of the first ribs which are the site of the luxation. Its existence is indicated by a protrusion, more or less marked, of the sternal ends of the cartilages. Acute distress, oftentimes an effusion of blood, ecchymosis, and fever appear soon after the injury.

Dr. Emmert also mentions the separation of certain of the costal cartilages, particularly those of the sixth, seventh, and eighth ribs, from their anterior attachments in children as the result of great general weakness, but such cases are evidently foreign to the lesion of which this paper treats.

(To be concluded.)

The Use of Glycerin in Inflammatory Affections.—Professor Semmola recommends the following formula for the internal use of glycerin:

\[
\text{Glycerin, } 30 \text{ parts by weight; citric or tartaric acid, } 2 ' \quad ' \quad 2 ' \quad \text{water, } 590 ' \quad ' \quad \text{One or two teaspoonfuls to be taken every hour.}
\]

A DIAGRAMMATIC SUMMARY OF SOME OF THE PRINCIPAL FEATURES OF CEREBRAL AND SPINAL ARCHITECTURE.

BY AMBROSE L. RANNEY, M. D.

I have endeavored, as a sequel to my previous article, to represent in a schematic way the mutual relations of the encephalic and spinal centers, and to show the mechanism by which various phenomena observed during life may be explained. Let us examine different parts of the diagram separately.

1. The Cerebral Hemispheres. The circles (M) represent the motor and psychic centers of the convolutions; the circles (S) represent the sensory centers of the same. The lines in the diagram which connect these centers with the basal ganglia are the fibers of conduction to and from the cells of the gray matter of the convolutions (cerebral cortex). These fibers are the so-called "peduncular," "radiating," and "converging" fibers of different authors (page 458 of vol. xxxvii). Taken as a whole, they constitute the so-called "corona radiata." The lines marked (a) represent the so-called "associating fibers" (page 458 of vol. xxxvii). Throughout the diagram, all efferent fibers, or those which carry impulses from the various centers, are represented by unbroken lines, and all afferent fibers, or those which carry impulses to the various centers, are dotted lines. The arrows also show the direction of the currents. The fibers connected with the centers of the hemispheres can be traced in the drawing downward to their union with the cells of

the basal ganglia, the mesencephalon, the medulla, and the spinal cord. In any of these regions separately, or in all simultaneously, the cerebral cortex can probably exert its direct influence; the smaller centers are then either overpowered or controlled in their respective automatic actions by the great center of intelligence—the cerebrum.

2. The Basal Ganglia.—The corpus striatum (C. S.) is shown to be associated with the motor regions of the cortex (M). A direct communication probably also exists between it and the optic thalamus (O. T.). The cerebellum is thought by some to communicate indirectly with it by means of the "processus cerebello ad cerebrum" (4). These three sets comprise its afferent fibers. Its efferent fibers (1, 2, and 3) pass to the cells of the crus, medulla, and spinal cord. The connection shown between the cerebellum and the so-called "motor tract" will help to interpret the view held by some that that ganglion assists the cerebrum in its control over the muscular apparatus of the body.

The optic thalamus (O. T.) has afferent fibers, which arise from the spinal cord, medulla, and mesencephalon (5, 6, and 7), and from the cerebellum (8). It is thus brought into relation with all sensory impulses derived from the spinal nerves, and also from those cranial nerves which are not motor in function. Impressions derived from sight, smell, hearing, and taste, as well as tactile impressions, and the sensation of pain, are probably more or less intimately associated with this ganglion. The efferent fibers of the optic thalamus are shown to lie in the posterior part of the corona radiata, and to distribute themselves among the sensory centers of the cerebral cortex (S). The fibers of direct communication between the optic thalamus and the corpus striatum (b) help to explain the ability of an animal to perform automatic co-ordinated movements after the cerebral hemispheres have been removed and the basal ganglia left intact. These phenomena are in marked contrast to the forms of reaction which take place within the hemispheres between the sensory and motor centers of the cortex; since consciousness and volition are evoked by the latter, while the former is purely automatic. Conscious appreciation of sensations and voluntary motion are only possible when the cerebral hemispheres are present.

3. The Cerebellum.—This diagram shows, in an imperfect way, the relations of the cerebellum to the paths of sensory and motor conduction. The sensory and motor centers of this ganglion (S’ and M’) have not been anatomically differentiated from each other, but we have reason to believe that both varieties exist. The afferent fibers of the cerebellum (9, 10, and 11) probably bring it into direct relation with tactile impressions by means of the spinal cord, with sensations of pain (l) by the same channel, and with various other impressions by means of nerves of special sense. Its efferent fibers (4 and 12) are related, in an imperfectly understood way, to the path of motor conduction. The most delicate feats of equilibrium are probably impossible without an intact cerebellum. This subject will be discussed hereafter. Each hemisphere of the cerebellum is now believed to be associated with the fibers of the opposite hemisphere of the cerebrum.

4. The Mesencephalon.—As shown in the diagram, this term includes all the parts comprised between the cerebrum above and the medulla below. The collections of gray matter, represented by the circles (M”) and (S”), comprise chiefly the so-called "substantia nigra" and the "red nucleus of the tegmentum." The fibers associated with them (1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, and 12) constitute, collectively, the basis and tegmentum cerebri of Meynert, which are separated by the substantia nigra. These two bundles have been described in the preceding lecture. The red nucleus lies beneath the corpora quadrigemina in the tegmentum or the sensory portion of the crus, and is in intimate relation with the fibers of the superior cerebellar peduncle (4). The corpora quadrigemina (not shown in the diagram) should be also included among the ganglionic masses of this region. The third cranial nerve is represented as structurally related to the mesencephalon. The optic nerve has also intimate relations with some of its parts.

The functions of the mesencephalic centers are too complex to justify any generalizations. All of the complex forms of muscular activity which are more especially elicited in response to some form of impression received from without by means of the nerves of special sense, such as locomotion, emotional expression, etc., are to be attributed chiefly, if not wholly, to these ganglionic centers. We know that the corpora quadrigemina are intimately associated both with the sense of sight and ocular movements, and that vision influences equilibrium to a very marked degree. The special attributes of the red nucleus of the tegmentum and the substantia nigra are, as yet, purely conjectural.

5. The Medulla Oblongata.—Within this ganglion the nuclei of origin of many of the cranial nerves have been found, and special centers which preside over important physiological functions have also been demonstrated. The circles (M”) and (S”) in the diagram are supposed to represent the sensory and motor collections of gray matter which give to this portion of the central nervous system its peculiar powers. The motor centers (M”) are represented as in communication with certain cranial nerve roots, and also with motor fibers which serve to connect the medulla to the corpus striatum and the ganglionic masses of the mesencephalon above, and the segments of the spinal cord below. The sensory centers (S”) are shown to be in relation with the sensory cranial nerve roots (the term “sensory” being used in its broadest sense to include all fibers bearing afferent impulses), as well as with the paths of cerebral and cerebellar sensory conduction (6 and 10). Thus it is that the cerebellum as well as the cerebrum probably is made cognizant not only of tactile sensations and pain impulses transmitted along the spinal tracts, but also of other facts which our special senses reveal to us. The view that the cerebellum acts in part as an "informing depot" for the cerebral hemispheres can be comprehended by a study of this diagram.

The fibers which are drawn in the diagram between the motor and sensory centers of the medulla help us to comprehend the probable mechanism of many forms of complex co-ordinated reflex actions, of which the medulla is capable when all the nerve centers above it have been removed. It is apparent that each of the segments of the
nervous system here depicted is capable, by means of commissural fibers, of an action of its own which is independent of those centers above it, but which may be controlled or overpowered by the higher centers when they are called into action.

6. The Spinal Cord.—The diagram shows the cells of the anterior horns of the spinal gray matter (A. C.) to be in connection with the fibers of the direct motor tract which we have now traced from the cerebral cortex downward (although some have been deflected from the direct path by the cells of the mesencephalon and medulla). These motor fibers of the spinal cord are prolonged, by means of the interposed cell (A. C.), as fibers of the anterior or motor roots of the spinal nerves. The cells of the posterior horns of the spinal gray matter (P. C.) are likewise shown to receive the afferent impulses conveyed to them from without by the posterior or sensory roots of the spinal nerves (as shown by the arrow), and to transmit them upward by means of fibers which connect them with higher ganglionic masses (5, 6, and 7). The exact paths of motor and sensory conduction through the spinal cord are not positively settled. The antero-lateral columns of the cord are commonly regarded as the chief motor paths, although all observers are not in agreement respecting the anterior columns. The sensory tracts probably run partly in the central gray matter of the cord, and partly in the lateral columns. Sensory impulses travel on the side opposite to that on which the nerves enter. The views held respecting the functions of the spinal columns will be given further on.

Finally, it will be observed that the motor and sensory cells of the spinal cord communicate directly. This arrangement allows of an automatic spinal action. Beheaded animals can be made to exhibit definite muscular movements when any irritation of the sensory nerves of the skin is employed to call them forth. A frog so mutilated will scratch with the opposite foot a spot on the leg which has been touched with an acid. Robin has observed similar phenomena in a beheaded criminal. These movements are purely reflex in type, because all parts which we know to be essential to consciousness or volition have been taken away. They can only be attributed, therefore, to a direct communication between the sensory and motor cells of the spinal segment. Many of the acts which constant and long-continued practice enable us to acquire during life—as, for example, the running of scales upon a piano—are unquestionably performed automatically by the spinal cord, without assistance from the higher ganglia, in many instances.

A NOVEL OPERATION FOR THE RELIEF OF INCONTINENCE OF FÆCES.

By CHARLES B. KELSEY, M. D.,
SURGEON TO ST. PAUL'S INFIRMARY FOR DISEASES OF THE RECTUM.

The patient, a man, aged twenty-seven, was originally sent to me two years ago by Dr. McCready, suffering from ischio-rectal abscess. Although this was at once operated upon, it did not stop the burrowing of pus, and eventually a fistula was formed, opening into the bowel well above the internal sphincter, and out on the buttock a considerable distance from the anus. This in turn was divided with the knife, but the result of the division of so much of the bowel and of both sphincters was a considerable degree of fecal incontinence, with all of its necessary attendant evils. Treatment of the incontinence by the passage of bougies, the use of cold, etc., resulted, after a year's continuance, in great benefit, so that the patient seldom soiled his clothing with feces, except when the bowels were unusually loose; but there was an occasional passage of a slight amount of feces, a frequent escape of rectal mucus, and a constant annoying sense of insecurity in the patient's mind which made him anxious for any further relief which surgery could afford. The actual cause of the open condition of the anus lay not so much in any weakening of the power of the sphincter, which always contracted firmly around the finger in the rectum, as in the peculiar shape of the anal orifice, resulting from the contraction of the cicatrix formed by the operation for fistula. This was situated on the left side, was firm, deep, and hard, and, by its contraction, had resulted in a decided drawing of that side of the anal orifice over still more to the left, so that no amount of sphincter contraction could close it. The condition may be seen by a glance at the diagram, in which C represents the cicatrix.

To remedy this deformity, I made with a Paquelin cau-
tery the burns represented by the lines 1, 2, 3, 4, and 5, and also removed two longitudinal strips of mucous mem-
brane from the inside of the bowel, clamping the tissue deeply with Smith's clamp, and using the cautery freely. The burns represented by the figures were also deep, going fairly down to the sphincter, and extending from well within the anus to the distance of an inch upon the skin, growing deeper as they reached the lower end.

The operation was followed by more pain and local distur-
banee than I anticipated, and there was at one time a bravy hardness in the cellular tissue of the right buttock which made me uneasy lest the patient should have another deep abscess worse than the first; but all this passed away, and, after three weeks' rest in bed, he was again able to at-
tend to his work. At the time of writing, three months have elapsed since the operation. The wounds have healed, the sphincter contracts firmly upon the finger, the anus is closed, and the discharge has ceased. In other words, the patient is cured by the production of a stricture at the anus sufficiently tight to close the orifice, and I have no longer any fear that I might have done too much in the operation and made his last state worse than the first by producing a stricture which would need constant future care. The burns
Book Notices.

The first edition of Mr. Nettleship's book, published in 1880, proved to be a success, and a very useful little volume to the student. The second edition comes to us enlarged, with the number of illustrations considerably increased, and containing also a chapter upon the Detection of Color-Blindness, by Dr. Thomson, of Philadelphia, an authority upon the subject. The work has not only been added to, but a large number of passages have been omitted, and a careful perusal of the book enables us to repeat, still more forcibly than in our review of the first edition, that it is a work of real value to the student. The author has done well in placing the Functional Disorders of Vision in a separate chapter, immediately following the chapters on Diseases of the Retina and Diseases of the Optic Nerve. In the chapter on the Examination of the Eye by Artificial Light there is included a section on Keratography and Retinography. Every chapter has been revised, so as to bring the work up to the present standard; and when one remembers how very great and wide-spread is the activity of our workers in the field of ophthalmology, it will readily be seen that this has been no small labor. There is very little to object to in the book, but we think it would be better not to use the term "cartilage" of the lid when speaking of the tarsus, for, though sanctioned by usage, it is faulty.

The first edition of Dr. Fenner's book was published in 1875. Since then the author has died, but prior to his decease the first edition had been revised and added to to some extent, with a view to a new edition. These revisions and additions have been incorporated by the publishers in the second edition, now published. The subject is divided into three parts. In turning over the pages of this handsomely printed and sufficiently illustrated work, we meet with numerous revisions of the text all through the work, all of which have assisted in raising the standard of the book. In the second part, on Physiological Optics, there is too little space given to the anatomy of the eye, and this, we think, is a great mistake. The third part, on Errors of Refraction and Accommodation, is the least satisfactory in the book, especially with reference to the examination and treatment of astigmatism. There has been added to this part a new section, on the Defects of Accommodation, Pareisis, Paralysis, and Spasm of the Muscles of Accommodation, which is good so far as it goes, but is altogether too brief. Under this head is also considered, though very briefly, the subject of myoties. Still, there is a great deal of very useful information contained in the work for students and general practitioners, and it is presented in a clear, concise manner. The paper and type are excellent, and most of the illustrations are very satisfactory.

BOOKS AND PAMPHLETS RECEIVED.

Annual Announcement of Trinity Medical School, Toronto. Established 1850. Incorporated by act of Parliament. In affiliation with the University of Trinity College and the University of Toronto, and recognized by the several Royal Colleges of Physicians and Surgeons in Great Britain. Session 1883–84. Twenty-third Annual Announcement of the Bellevue Hospital Medical College, 1883–84, with the list of graduates for 1883.

Medical Society of the State of Tennessee. Transactions, 1858, fiftieth annual meeting.

Pemphigus, and the Diseases liable to be Mistaken for it. By George H. Robé, M. D., Professor of Hygiene and Clinical Dermatology, College of Physicians and Surgeons, Baltimore, etc. Pp. 11. [Reprint from the "Medical News."

The Treatment of the Various Forms of Acne. By George H. Robé, M. D., etc. Pp. 7. [Reprint from the "Medical Chronicle."

Hints on the Treatment of Some Parasitic Skin Diseases. By George H. Robé, M. D., etc. Pp. 11. [Reprint from the "Medical Record."

Extirpation of the Uterus. By Paolo De Vecchi, M. D., Torino, Italy. Also, Note on Extirpation of the Kidney. Pp. 12. [Reprint from the "San Francisco Western Lancet."

THE PROGRESS OF THE CHOLERA.

While we do not think the alarmist’s time has yet come, and while we repeat the impression we stated last week, that there is not much probability that the cholera will reach our shores this year; it must be confessed that the situation is not so well calculated to inspire confidence as to the ultimate progress of the disease as it seemed to be a week ago.

The sanitary authorities in Egypt have by this time probably seen the folly of the policy of denying the existence of “true” cholera, and of imputing the deaths reported from it to this, that, and the other affection. On the other hand, the British Government, which, it was trusted, would feel under extraordinary obligation to put forth its full resources to prevent the spread of the infection to Europe, declines to quarantine vessels from the Egyptian port. “Egitto,” says one of our Italian contemporaries, “è in mano degli Inglesi e di Britannici.” A like feeling seems to exist elsewhere in Europe, for one of the powers is reported to have threatened a quarantine against all English vessels in case England continues to ignore the just demands of her neighbors in this matter. England is certainly amenable to this sort of persuasion, and we trust that it will be brought to bear upon her at the first sign of its necessity.

By contrast, the activity and determination of the Italians are gratifying, even if the Government has shown some undue zeal in maintaining its order that a vessel should go into twenty days’ quarantine at Spezia after, as is alleged, the occasion for the order had been shown to be a clerical error in the vessel’s bill of health. Instead of going to Spezia, by the way, the vessel in question proceeded to Trieste, the inhabitants of which city are no doubt much interested in the clerical error alluded to. The people of Brindisi had previously refused to allow the same vessel to land the Indian mail, even after it had been fumigated. In Germany, also, a quarantine of six days has been ordered for vessels from suspected ports. Russia has followed the same course. Evidently these nations do not trust cotton merchants and canal companies. It is officially stated that a man who died of a suspicious disease in Berlin on Thursday of last week was not suffering from cholera.

The British Government may yet find its policy of inaction justified by events, and we trust that such will be the case. A little less reliance on its officials in Egypt, however, and somewhat more deference to the wishes of other governments, would be reassuring. The view entertained by the British authorities is certainly not shared by the whole people of England, for we find a writer in the “Pall Mall Gazette,” Dr. B. G. Jenkins, taking a most gloomy view of the situation. Dr. Jenkins, who professes to have made a study of cholera, maintains that there are two forms of the disease, one originating in India and the other in Arabia. It is the Arabian variety, he asserts, that has always heretofore overrun western Europe, and the present outbreak in Egypt is more readily traced to Mecca than to the Ganges. His inference is, that before the close of the year cholera will be raging in every quarter of the globe. Without accepting Dr. Jenkins’s theories, the part of wisdom may nevertheless lie in acting as if they were proved.

Another element of danger is to be found in the fact that an independent focus of infection has come to light. We refer to the prevalence of the disease at Shanghai and Swatow. In view of this fact, the health officers of Atlantic ports will have to keep watch of pretty much our whole commerce, instead of concentrating their attention upon vessels arriving from the Mediterranean, and the authorities on the Pacific coast must share their vigilance.

THE SUMMER TENEMENT-HOUSE SERVICE OF THE BOARD OF HEALTH.

So far as we can judge by the list of appointments made by the Board of Health last week, in the matter of supernumerary medical officers for special services in visiting the sick poor during the remaining weeks of the hot season, the board has again displayed the good sense that has marked its course in general. We understand that about half the appointees have performed the same service during one or more previous summers, and have thus gained a good working familiarity with the requirements of the position; while among those whose names now figure in the list for the first time there are several whose standing is such that their consenting to serve in so trying a capacity can scarcely be set down to other motives than a genuine desire to be of service to their less fortunate fellow men. Certainly, there are some among them who can not have been tempted by the remuneration that the board finds itself able to allow.

To spend a great part of each day during the months of July and August in climbing the dark passages leading to the noisome abodes of the very poor; to pit their art, their counsels, and their humanity against wretchedness and disease, with ignorance, vice, and all manner of malign influences combining to make the contest appallingly unequal; to encounter distrust, petulance, and even downright brutality among those they are trying to serve—to devote to such a work as all this implies the weeks that in too many instances their own jaundiced condition demands should be spent in recuperation argues the possession of a spirit of enthusiasm, whether in the cause of humanity or in that of science, that the profession gets credit for only in very general terms.

Regarding merely from a medical point of view, this summer tenement-house service is unpromising. In the first place, it is in general out of the question for the physician to secure for his poor patients the sanitary and dietetic auxiliaries that are so all-important in the conflict with disease. He may furnish drugs, and they may be most appropriately chosen and most intelligently and faithfully administered, but he can not supply pure air, save for the brief periods covered by the free steam-
boat excursions to which he can obtain admission for his patients, nor can he do very much toward insuring that the food furnished them is not of a sort to do positive harm. Most discouraging of all, perhaps, is the senseless clamor for medicine, and the deaf ear turned to advice, that one meets with in this sort of practice. This, to be sure, is not confined to the victims of poverty and to the uneducated, but is met with at every turn, alike among high and low; for, like the sick man of old, the ailing are ready to do "some great thing," but show only incredulity when told to "wash and be clean." Among the well-to-do, however, this drag on the resources of medicine may be foiled with the aid of a placebo, but with the poor and ignorant such artifice calls for much more management.

But, with all the drawbacks they have to encounter, there can be no doubt that the summer medical corps acting under the Board of Health do really succeed in doing a great amount of good, unquestionably saving not a few lives that would otherwise be lost. We are persuaded, therefore, that no other disposition of the public funds could be made that would result in a greater gain to the community or a larger measure of relief to the poor.

STINGINESS IN HOSPITAL ADMINISTRATION.

The Directeur de l'Assistance publique of Paris has addressed a circular letter to the directors of the several hospitals, calling attention to the unnecessary consumption of beer in the hospitals, whereby, he intimates, a drain is set up on his budget that he finds it difficult to meet. With the graceful ease with which non-medical persons in authority over medical institutions are accustomed to decide questions to suit their own views, the director says: "Beer, you know, is neither food nor medicine"—which reminds us of the "decision" of a certain Kentucky judge that sprinkling was valid baptism, the case being that of a murderess who wished to be immersed in a river before her sentence was executed.

The director has "decked," therefore, that there shall be no more beer served to the patients, save on the order of the visiting medical officer in each individual case, which order must be approved at the director's office—truly a roundabout way of getting a prescription filled. Notwithstanding the director's decision that beer is neither food nor medicine, it is certainly thought to be both by a respectable number of men who are disqualified from throwing any light on the question only by the fact of their having made dietetics and medication the study of their lives. They can not, of course, free themselves from this embarrassing drawback, and it may be that numerous other articles besides beer, which they have been accustomed to prescribe for their patients under the idea that they were food or medicine, might, if subjected to official illumination, turn out to be neither the one nor the other. M. Quentin might perform some brilliant exploits in such a line of inquiry. But, really, there is no occasion for him to assign a reason for his acts. Let him take a hint from our American managers of hospitals and dispensaries, and boldly announce that the amount of quinine and iodide of potassium ordered must not exceed a certain maximum, or direct the apothecary to substitute cinchonine for quinine, to put up only half the quantity of any mixture ordered, to issue infusions when tinctures are called for by the prescription, and the like. Then, too, a cheap quality of other might be provided, as is said to have been done lately in Philadelphia.

There are innumerable other devices that are perfectly well known to our hospital managers, the unflinching enforcement of which enables them to find money for useless but showy accessories, including an annual report that is generally not worth the paper it is printed on, and might with advantage be condensed into a newspaper paragraph. Evidently, however, M. Quentin is on the right road to become a "boss," for, ignoring the opportunity for genuine economy afforded by his own office, in which, as the director himself stated in 1877, the number of persons employed might be reduced twenty-five per cent. without detriment to the service—ignoring this, he has chosen to make his little show of economy by depriving the patients of an article that many prejudiced and old-fashioned people will persist in regarding as both food and medicine.

EIGHT OUNCES OF BLOOD.

Some of our readers may remember Dr. Garrigues's case of Transfusion in Gas Poisoning, published in our issue of March 3d. The case was that of a man who went to bed in a hotel after having blown out the gaslight in his room. It appears that the porter of the house, one Banks, furnished the blood employed in the operation of transfusion, eight ounces in amount. Banks now brings suit to recover $250, the value, he alleges, of "goods sold and delivered," meaning the eight ounces of blood, together with subsequent attendance as a "nurse."

As we understand it, Banks fails to specify what portion of the gross sum he considers to be the value of the "goods sold and delivered," and what portion he claims for professional services. This is ungenerous in Banks, for, if the case ever comes before a jury, they will need all the light they can get, including Banks's opinion as an expert, on the question of the commercial value of fresh human blood "delivered." He is said to have testified, however, that on the occasion of the transfusion Dr. Anderson, one of the physicians in attendance, told him that "every drop of his blood was worth ten cents." But even Banks himself is too modest to use this enthusiastic remark as the basis of his estimate, for at that rate, assuming that the blood in question amounted to eight fluidounces, instead of eight ounces by weight, in round numbers the "goods sold and delivered" would come to over $300.

On the other hand, we have the testimony of Dr. Garrigues, who stated before Justice Kelly that he had performed transfusion more than once at the Maternity Hospital, and had never had any difficulty in getting the requisite amount of blood from a healthy carpenter "in exchange for one dollar and as much whisky as he took blood." Here, then, is a tangible precedent, one that perhaps it might fairly be said ought to be held as governing the market for the time being—only it has one awkward
defect in that the quality of the whisky is not stated. Moreover, a complication arises at once in the question as to the comparative value of a healthy porter's blood and that of a negro porter. If we may credit the author of "Hudibras," Tagliaozzi was much given to the use of porters' brains for the material of his supplemental noses, but we are not told that Tagliaozzi's porters were of the African race. It seems not unlikely, indeed, that even the renowned Italian would have preferred a white carpenter for that particular purpose; and that such would have been his patients' choice we can scarcely doubt. But we have no wish to injure Mr. Banks's chances of getting the $250, and we will refrain from further suggestions calculated to affect the blood market.

MINOR PARAGRAPHS.

A DECISION LIMITING THE POWERS OF CORONERS.

It has been rather a common occurrence in many localities for coroners to hold inquests in cases of death where there was no reasonable ground to suspect violence, with the object of securing the fees which the law gives in such cases. In a case of this kind in Pennsylvania the county officials refused to pay the fees, and suit was brought to compel payment. It was brought out on the trial that the deceased was nearly eighty years old, that he had been sick for some days, during which time he was under the care of a regular practicing physician; that he died a natural death in his own house, surrounded by his family; that there was nothing suspicious, sudden, or extraordinary connected with it; and that all these facts were communicated to the coroner before he summoned the inquest.

All this evidence was rejected on the trial, on the ground that the coroner was a judicial officer, and there could be no interference with him in any case where he chose to exercise the functions of his office.

The Supreme Court, where the case was taken on appeal, however, took the opposite view, and reversed the decision, which had been in favor of the coroner. The opinion was in part as follows: "The object of an inquest is to seek information, and obtain and secure evidence in case of death by violence or other undue means. If there be reasonable ground to suspect it was so caused, it becomes the duty of the coroner to act. If he has no ground for suspecting that the death was not a natural one, it is a perversion of the whole spirit of the law to compel the county to pay him for such services. In this case the inquest found the decedent came to his death 'from a paralytic stroke.' Nay, more, if under the facts offered in evidence a coroner may hold an inquest, he may, in his discretion, at the expense of the county, order a post-mortem examination, whereby those bound to the deceased by the nearest and most tender ties may have their feelings inerated in every case of natural death. The idea is preposterous, and abhorrent to all the finer emotions of human nature. It was error to reject the evidence. If he had sufficient cause to justify his action, he may still show it. If he had not, there is no good reason why the county should pay for unnecessary and meddlesome services."

BEER IN THE PARIS HOSPITALS.

What may be called a protest against M. Quenlin's decree stopping the issue of beer to the patients in the hospitals of Paris, an account of which will be found in a preceding article, has been signed by the following-named hospital surgeons: Le Fort, Tréhat, Duplay, Depail, Panas, Verneuil, Despré, Tillaux, Nicaisse, Lannelongue, Richelot, Humbert, Reclus, Terrillou, Monod, Schwartz, Bouilly, Pozzi, Marchand, Berger, Gillette, Le Dento, Delens, Lucas-Championnière, Th. Angli, Pohillion, Guéniot, Marc Sée, Cravelhier, Horteloup, Pérrier, Terrier, Kirnisson.

THE CHOLERA IN EGYPT.

Ninety-six deaths from cholera are reported to have occurred last Saturday at Damietta, forty-eight at Mansurah, six at Samand, six at Shirbin, and one at Alexandria. On Sunday there were eighty-eight at Damietta, sixty-four at Mansurah, nine at Samand, seven at Shirbin, and one at Alexandria. Fifty-seven are said to have occurred at Damietta on Monday, and at that place famine has been added to the pestilence. An attempt was recently made by several European residents to break the cordon around the town, and some of them were wounded. Several of the gendarmes forming the cordon have been attacked with the disease, and fresh cordons have had to be thrown around the infected ones.

YELLOW FEVER.

Last week there were infected ships at Ship Island and at the Pensacola quarantine station. Surgeon-General Hamilton, of the Marine-Hospital Service, does not think an outbreak likely in the United States this season, but urges the need of strict quarantine regulations. He thinks Vera Cruz is the chief point to be watched, and, if necessary, a United States inspector will be sent there. The disease is said to be spreading slowly in Havana, which port the steamship City of Mexico left last Saturday, with supposed cases of yellow fever on board, bound for New York. Since the 10th inst., all northward-bound vessels on the Mississippi River have been required to be inspected at Fort Adams before being allowed to land at any point in the State of Mississippi. At Galveston, a patrol is guarding the beach, to prevent the landing of persons from an infected Norwegian bark lying-to twelve miles out.

THE COMPARATIVE POISONOUS PROPERTIES OF COAL GAS AND WATER GAS.

A report lately sent to the Brooklyn Board of Aldermen by Health Commissioner Raymond gave the following comparative analyses of coal gas and water gas, made by Professor Remsen, of the Johns Hopkins University:

<table>
<thead>
<tr>
<th></th>
<th>COAL GAS</th>
<th>WATER GAS</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Per cent.</td>
<td>Per cent.</td>
</tr>
<tr>
<td>Carbon dioxide (carbonic acid)</td>
<td>0.9</td>
<td>0.3</td>
</tr>
<tr>
<td>Illuminants (ethylene, etc.)</td>
<td>4.3</td>
<td>12.35</td>
</tr>
<tr>
<td>Carbon monoxide (carbonic oxide)</td>
<td>7.9</td>
<td>23-25</td>
</tr>
<tr>
<td>Hydrogen</td>
<td>50.2</td>
<td>30.3</td>
</tr>
<tr>
<td>Marsh gas</td>
<td>25.8</td>
<td>21.45</td>
</tr>
<tr>
<td>Nitrogen (by difference)</td>
<td>7.8</td>
<td>6.85</td>
</tr>
</tbody>
</table>

Professor Remsen's opinion was that water gas was not at all dangerous if used with the same precautions as coal gas.

THE SANITARY CONDITION OF THE STATE CAMP.

A large sick list is reported from the Sixty-fifth Regiment, in the State Camp of Instruction at Peekskill during the past week, thirty-three men having been reported at sick call on Sunday, and forty on Monday, mostly with diarrheal attacks. While it is not unlikely that much of this sickness is to be imputed to
imprudent exposure during the raw weather of Saturday night and Sunday, the necessity of keeping a close watch on the police work should not be lost sight of. It is noteworthy that, during the week that the Seventh Regiment was in camp, not a single case of sickness occurred.

THE STATEN ISLAND EPIDEMIC OF PLEURO-PNEUMONIA.

Last week we mentioned the prevalence of infectious pleuro-pneumonia among the cattle of Staten Island. We are glad to be able to state now that the State Board of Health has sent so competent a veterinarian as Professor Law, of Cornell University, to investigate the probable causes of the outbreak, and to examine into the methods employed for limiting the spread of the disease.

POLITICS IN PROFESSIONAL APPOINTMENTS.

A correspondent of the "Tribune" calls attention to the recent summary dismissal of Dr. A. D. Wilbor from the office of superintendent of the State Institution for the Blind, at Batavia, remarking that Dr. Wilbor has held the position for the last five years, during which time he has given entire satisfaction, and charging that the removal is made on party grounds. According to the writer in question, it does not appear that the deposed superintendent has played the part of a partisan, or that his political course has been at all active, but the allegation is made that the place was wanted for a gentleman belonging to the opposite party.

For the credit of our State administration, we trust that some explanation will be made that shall give the case a different color. Venal and grasping as our politicians are, they have usually had the decency to refrain from dismissing competent medical officials as a party measure. To bring these appointments within the range of the accursed rule "to the victors belong the spoils" would take us one step farther away from the purity of our forefathers.

NEWSPAPER NOTORIETY.

We are willing to believe that it is generally with the best possible intentions that the managers of the newspapers bestow on members of our profession the fulsome laudation that so often attracts notice and provokes a smile. There is so little charity in the world that the physician thus fluffed is pretty sure to be credited with having inspired the tributes in question; in the great majority of instances unjustly, we do not doubt. A flagrant instance has lately come to our notice, in which one of the Sunday papers gave four separate insertions to a paragraph in which a well-known member of the New York profession was characterized as "the greatest living physician." We happen to know that the gentleman alluded to was mortified and angry at the occurrence, as any man of self-respect could not fail to be. And yet he realized that the obnoxious paragraph was intended as a genuine tribute. It is passing strange that men so well acquainted with the world as to be able to manage a newspaper should not perceive that a person of sense always resents gross flattery.

RIVALRY AMONG CORONERS.

The delights of our system of coroner's law seem to have no end. The latest illustration is furnished by a case on Staten Island, in which the physician in attendance, who is also a coroner, held an inquest on the body of his deceased patient. He had been preceded, however, by a more enterprising coroner from a neighboring village. It is comforting to learn that both inquests led to the same conclusion as to the cause of death.

PRIZES FOR FRENCH ARMY SURGEONS.

The French minister of war announces two annual prizes, a gold medal or 500f. each, for the best essays, by officers of the corps de santé militaire, on subjects connected with military medicine; also a tricennial prize, of the same value, for the best essay in chemistry. The minister expresses regret that the funds at his disposal will not allow him to offer such valuable prizes as are given by other nations.

THE ENCROACEMENTS OF MIDWIVES IN FRANCE.

Some midwives in the Department of the Haute-Garonne, in France, having advertised to treat diseases of women, in addition to their legitimate practice of midwifery, their right to do so became a question. A committee appointed by the Société de médecine légale to consider the matter, has reported that the midwives can not be prosecuted for their advertisements, but that any overt act on their part in the way of other practice than that of midwifery will render them liable to prosecution.

A NEW JOURNAL—"THE POLyclINIC,"

"The Polyclinic," a new sixteen-page monthly journal, has been started by Messrs. P. Blakiston, Son & Co., of Philadelphia. The first number, dated July 10th, contains several meritorious communicated articles, an editorial giving excellent advice to the Medical Society of the State of Pennsylvania, and a good variety of selected matter. The word adopted as the name of the new journal has certainly become amazingly popular, and we do not doubt that the publication will prove worthy of its title.

A WISCONSIN SURGEON'S ALLEGED INHUMANITY.

A story has lately been going the round of the newspapers to the effect that a child's life was lost in Wisconsin recently as the result of an injury, and that a surgeon refused his services in the case because the family would not dismiss a homœopathic practitioner who was in attendance. The "Evening Post," of New York, having commented on the case, Professor William W. Seymour, of Troy, has addressed the following letter to that paper:

I am greatly surprised that a journal usually so quick to grasp the vital factors of every question can be so blinded by partisanship as to take the position the "Evening Post" does in its last issue regarding the liability of physicians and surgeons for declining to render services when called on, even in cases of life and death. The opinion used to prevail among the ignorant classes here that, as to the general public, the medical man was obliged to respond to every demand on his services or stand a lawsuit; some made the attempt, but ignominiously failed. The physician owes the general public no more than any other citizen, be he merchant, manufacturer, or priest, and not so much as a lawyer, who is an officer of the court, and may be assigned to defend a case. If, in the case of the Wisconsin surgeon, he was the only one capable of doing what was needed in the case, he, and he only, was the proper one to operate, to conduct the after-treatment, judge of the propriety of counsel and the fitness of counsel. By your very premises you state that the family practitioner was not a surgeon, and not competent to do what was necessary, and yet you apparently regard the surgeon as inhuman because he would not be trammled by a man who could not do what he himself could for the case, and whose medical practice, if sincere, is founded on dogmas positively preventing any agreement. If the surgeon is worthy of the slightest responsibility in
MINOR PARAGRAPHS.

[N. Y. Med. Jour.,

such a case, he should have absolute control of its treatment and the right to name his associates.

You have only blame for the man equal to the case mentioned, but none at all for the man who, self-confessedly incompetent, would not throw up his connection with the case. The inhumanity lies with the practitioner who knew he could not render the needed services, but who tenaciously held to a connection with the case he had not the skill to treat; and with the parents, who, by their partisanship, wished to trammel the only capable man by forcing upon him this self-confessed incompetent as an adviser. As to the liability to an indictment for manslaughter in the event of a fatal termination to a case such as you mention, I beg leave to differ from the "Herald" and the "Evening Post"; and hold that every practitioner has a moral and legal right to decline to render his professional services. The only persons to whom a practitioner owes any professional obligations are his loyal, confiding patients; those who rest on his skill, integrity, and sympathy; those who, by their friendship, love, and loyalty, have helped him to fight the battle against competition, chicanery, and ignorance. To these, rich or poor, every true physician will gladly render his best skill. To others he owes absolutely nothing, so far as his professional capacity is concerned. The fact is, the public prefers to have all the obligations and self-sacrifices on the side of the physician; it wants the privilege of decreeing his professional skill and his moral character, and of building up his rivals; but, when the latter are unequal to any situation, they also want him to answer without any hesitation the summons of those whose whole previous course has been to injure him, and be grateful for the opportunity, or to run the risk of an indictment for manslaughter. If a few cases in each community in which the irregular or incompetent are unequal to the situation are allowed to die for want of the care and counsel of competent physicians, society will put itself in the hands of competent men. And as to the case you have chosen as a text, it is quite sure that in that vicinity future cases of fractured skull will be put in the hands of some one else than of the homœopath who could not give the needed surgical care. If the strong men in the profession should thus treat the weaklings and knaves of every school, the weaklings and knaves would go to the wall, and a few funerals be the saving of many to society.

The "Evening Post" makes the following remarks on Dr. Seymour's letter:

Physicians and patients will read with interest the letter of Dr. Seymour on the medical code dispute, published elsewhere. With regard to the Wisconsin case, to our comments on which he refers, he seems to be laboring under a misapprehension. The regular physician was said to have deserted the patient, not because the family physician was not a surgeon, but because he was a homœopath. Dr. Seymour takes precisely the view of the matter that we expressed—that human life is a trifle compared with devotion to principle; that loyalty to the code is more important than health; while he adds to this the important doctrine, which we confess we forgot to dwell upon, that the only persons to whom a doctor has any obligations whatsoever are "loyal, confiding patients," whom he can rely upon to help him fight the battle with the homœopaths and other designing foes. This picture of the Strong Man, surrounded by his little band of patients, making a gallant stand against the "weaklings and knaves" who wish to save as much human life as possible, is as striking as anything the code controversy has brought out.

THE SUPPORTERS OF THE OLD CODE IN THE STATE OF NEW YORK.

The Council of the New York State Medical Association for Upholding the National Code of Ethics has issued a circular, dated June 21st, in which the numbers of those who uphold the old code in the various counties of the State are given as follows:

Albany, 40; Allegany, 14; Broome, 29; Cattaraugus, 14; Cayuga, 20; Chenango, 26; Chemung, 2; Chenango, 46; Clinton, 27; Columbia, 14; Cortland, 22; Delaware, 16; Dutchess, 40; Erie, 107; Essex, 14; Franklin, 15; Fulton, 10; Genesee, 13; Greene, 17; Herkimer, 25; Jefferson, 23; Kings, 149; Lewis, 11; Livingston, 11; Madison, 19; Montgomery, 18; Monroe, 53; New York, 742; Niagara, 25; Onondaga, 66; Ontario, 21; Orange, 18; Orleans, 16; Oswego, 29; Otsego, 15; Putnam, 7; Queens, 44; Rensselaer, 74; Rich- mond, 11; Rockland, 9; St. Lawrence, 13; Saratoga, 27; Schenectady, 12; Schoharie, 12; Schuyler, 12; Seneca, 21; Steuben, 18; Suffolk, 18; Sullivan, 17; Tioga, 19; Tompkins, 13; Ulster, 19; Warren, 18; Washington, 10; Wayne, 24; Westchester, 44; Wyoming, 12; Yates, 9.

THE BENEFICENT WORK OF ST. JOHN'S GUILD.

The guild's Seaside Nursery being open for the season, the trustees give notice that destitute sick children will be conveyed to the institution by the boat that leaves the foot of King Street (Pier 38, North River) at 8 A.M., and the foot of Fifth Street, East River, at 9:30 A.M., every Tuesday, Thursday, and Saturday. Only sick children can be admitted, and they must not be affected with any contagious disease. A physician's permit is required, blank forms for which are supplied by the guild. Like restrictions apply to the excursions on the same boat, except that healthy children under six years of age are taken.

It is not easy to overrate the good that results to the sick poor of New York from the work of St. John's Guild. For many summers past the excursions have been carried on regularly under competent medical direction, and now the nursery is added to the beneficent measures taken by the organization.

THE UNION PROTESTANT INFIRMARY, OF BALTIMORE.

Wg learn from the "Maryland Medical Journal" that an arrangement has been made by which the private rooms of the infirmary may be occupied by patients continuing under the care of their own physicians, even if the latter are not members of the regular staff of the institution. The plan strikes us as commendable, provided it can be carried out without irritating friction in the matter of details.

NEWS ITEMS.

PROCEEDINGS UNDER THE MEDICAL PRACTICE LAW have lately been begun by the Medical Society of the County of New York against George H. Schwab, Bruno C. Lennar, Robert Hayes, and Désiré A. Protin, charged with practicing medicine without a license or a diploma, and with not having registered at the County Clerk's office. Hayes professed to have a diploma, and pleaded ignorance of the registration law. On the strength of this statement he was paroled. The others are held for trial, each under bonds of $800.

AN ALLEGED CASE OF HYDROPHOBIA.—A boy is said to have died lately at Fort Hamilton, L. I., of hydrophobia, supposed to
have resulted from the scratch of a cat, the theory being that the cat had had an encounter with a rabbit, and had imbued its claws with the virus of the disease.

Liquor Disguised as Medicine.—The tax on so-called "patent medicines" having been removed, it has been decided by the Commissioner of Internal Revenue that such preparations as "eye and rock" are subject to taxation as rectified spirits, and that dealers who sell them must pay a special tax as liquor-dealers.

The St. Louis Medical Society has lately been engaged in a hot discussion of the code question, and has repudiated the resolutions introduced in its name by Dr. Pollak at the recent meeting of the American Medical Association. Dr. Pollak defended his course in a very vigorous speech, and from the reports that reach us he has a large and lively following.

The Harvard Medical School.—Of the seventy-three gentlemen who received the degree of doctor in medicine at the recent annual commencement, six had taken the four years' course.

The University of Würzburg.—It is reported that Dr. L. Grosley is to have the chair of psychiatry, and Dr. C. Mather-stock that of cutaneous and venereal diseases.

The University of Prague.—The chair of general and experimental pathology has been offered to Dr. Spina.

Dr. N. C. Goldsborough, of Louisville, is said to have been tendered the position of Demonstrator of Anatomy at Atlanta, Ga.

Professor Benjamin Ball, of Paris, has been elected a member of the Section in Medical Pathology of the Académie de médecine, in place of the late Dr. Wolillez.

Professor Humphry has been appointed to the chair of surgery lately created in the University of Cambridge, England.

The Pennsylvania Anatomy Law.—The following-named gentlemen have been elected officers of the Board of Distribution, having charge of the allotment of dissecting material to the different colleges: President, Dr. Joseph Leidy; Secretary, Dr. R. W. Deaver; Treasurer, Dr. J. M. Mears; Executive Committee, Dr. W. W. Keen, Dr. A. R. Thomas, and Dr. L. W. Steinbach.

The Pollution of the Boston Water Supply by batters in the reservoir basins near Natick has engaged the attention of the Boston Water Board, which has taken action looking to a prohibition of the practice. It is understood, however, that the people of Natick are resolved to maintain their right to bathe there.

The Boylston Prize for the best essay on "Measles, German Measles, and Allied Diseases," has been awarded to Dr. P. M. Braidwood, of Birkenhead, England. Our impression is that this is not the first time the prize has gone out of the country.

Body-Snatching in Pennsylvania.—Dr. Charles E. French, described in a press dispatch as a convict in the penitentiary at Erie, is accused by his father-in-law of complicity in the robberies of graveyards that attracted so much notice in Pennsylvania a few months ago. French denies the charge, and alleges that his father-in-law is insane.

Small-Pox in Pennsylvania.—Five cases were reported to the Lancaster Board of Health on Friday of last week. Several cases are reported from Providence, a suburb of Scranton.

Malarial Diseases in Connecticut are becoming more prominent, according to a recent report by the secretary of the State Board of Health, Dr. C. W. Chamberlain, of Hartford. Occasionally, he says, a case of congestive chills is seen.

Suicide of a Physician.—The painful story reaches us from Alabama that Dr. Lee Pinkston, living near Montgomery, lately committed suicide, in consequence, it is supposed, of a state of melancholy into which he had fallen after having caused the death of one of his children with a dose of morphine which he mistook for quinine. The poisoning took place several years ago.

Removal of an Asylum Superintendent.—The superintendent of the lunatic asylum of Berks County, Pa., is reported to have been removed by the Poor Directors, as the result of an investigation into charges that had been brought against him of ill-treating the insane.

An Alleged Chinese Diploma was shown by a Celestial practitioner in Arizona who was lately arraigned for illegal practice, but the court is said to have looked upon it as a laundry bill, and to have imposed a fine of $100.

Professor Huxley has been elected president of the Royal Society of London.

OBITUARY NOTES.

John A. Lidell, M. D.—Dr. Lidell died at his residence in this city on Sunday, the 8th inst., in the sixtieth year of his age. He was a graduate of the Albany Medical College, class of 1848, and a member of the Academy of Medicine and of the Pathological Society. The deceased gentleman was a man of notable analytical power as a writer, and he contributed many valuable articles to medical journals, most of them relating to surgical subjects. In particular, we remember an article of his that was published several years ago in the "American Journal of the Medical Sciences," on Injuries of the Head. Dr. Lidell was not personally known to the greater number of his colleagues in New York, and as a practitioner his field was restricted, but by the few who really knew him he was warmly esteemed. During the late civil war Dr. Lidell did excellent service as Inspector-General of the Army of the Potomac, and his funeral, which took place on Tuesday, was conducted by one of the posts of the Grand Army of the Republic.

Richard T. Maxwell, M. D., of San Francisco.—A native of Philadelphia, where he obtained his degree from the University of Pennsylvania, and for some time a surgeon in the navy, Dr. Maxwell was one of the earliest representatives of the medical profession to settle in California, where he achieved prominence as a practitioner, and was widely known and esteemed. He died, June 29th, of Bright's disease, and was buried on Sunday, July 1st, from the hall of the Society of California Pioneers, of which he was a member.

Erastus O. Pinney, M. D., of Melrose, Mass.—Dr. Pinney died suddenly on Sunday, the 8th inst., in his seventy-fourth year. He was a graduate of the Harvard Medical School, and for many years had been a practitioner in Melrose, where he was greatly respected.

Benjamin Bell, F. R. C. S. Edinburgh.—Mr. Bell, a general practitioner in Edinburgh, better known in this country by his contributions to surgical literature, died June 13th. He was the son and grandson of well-known surgeons, and was connected with various charitable institutions in Edinburgh, of one of which, the Eye Infirmary, he was one of the founders.

Professor Emilio Cipriani.—This distinguished surgeon, who was also a member of the Italian Senate, died on the 16th of June, at Rome. He was a native of Florence.
PROCEEDINGS OF SOCIETIES.

NEW YORK OBSTETRICAL SOCIETY.

A stated meeting was held April 3, 1883, Dr. C. C. Lee, President, in the chair.

Dr. P. F. Munde presented four specimens, with histories, as follows:

I. OVARIAN CYST WITH LIMPID FLUID, SIMULATING A CYST OF THE BROAD LIGAMENT.—The patient was a woman, thirty-seven years of age, upon whom he operated at the Mt. Sinai Hospital in February last for removal of a supposed unilocular cyst of the left ovary. She had noticed enlargement of the abdomen for a year before, and during the preceding three or four months the symptoms and the physical appearances had been such as to lead to the diagnosis just mentioned; but, on cutting down upon the tumor, its contents were found to be perfectly clear, like those of a cyst of the broad ligament, and for a moment it was believed that a mistake had been made as to the real origin of the growth. On proceeding with the operation, however, the tumor was found to have a broad pedicle, and to consist of a large ovarian cyst, with several small cysts at its base. The patient recovered, and left the hospital on the twenty-fourth day. The cyst contained sixteen pints of fluid.

II. Batty's Operation for Dysmenorrhea and Pelvic Neuralgia.—A nurse, a widow thirty-seven years of age, had been in the medical wards of the Mount Sinai Hospital for about eight months, suffering from neuralgia pains in the pelvic region, extending down the right thigh, and from hysterical symptoms. At the end of that time she was transferred to Dr. Munde's service, where she was kept under observation for about two months, with the hope that some relief might be given by other means than the administration of opium, which she had been taking in considerable quantity. The only pathological condition discovered was what was believed to be thickening of the broad ligaments. There was a history of pelvic cellulitis. The patient stated that six years before she had suffered in a similar manner, and that Dr. Schramm, of Dresden, amputated the cervix for, as she believed, enlargement of the womb. The operation was followed by relief of two years' duration. The only means which seemed to offer any prospect of relief on the present occasion was Batty's operation, with or without removal of the tubes, and it was doubted whether, without more definite pathological indications, it was justifiable to resort to this, but he finally yielded to the patient's wishes, and, on the 28th of February last, performed the operation. Both ovaries with their tubes were removed. The right one was free, the left adherent, but no diseased condition was apparent. During the first twenty-four hours after the operation the patient was very irritable, and a large amount of Magendie's solution was required to keep her quiet. The temperature on the second day rose to 105° Fahr., but was controlled by cold water passed through a coil of rubber tubing placed upon the abdomen. Within a few days the patient recovered entirely from the operation, the pain of which she had complained before ceased at the end of three weeks, all narcotics were stopped, and it seemed that an excellent result was likely to be established permanently. Soon afterward, however, the old symptoms of neuralgia and hysteria returned, and were now worse than formerly. With regard to the title of the operation, Dr. Munde agreed with the opinion expressed by Dr. Martin, of Berlin, in a recent publication—viz., that the term "Taft's operation" should be confined to that class of cases in which the diseased tubes were removed, either with or without the ovaries.

III. CYST OF THE BROAD LIGAMENT CONTAINING THIRTY-

eight Pints of Fluid.—A woman, thirty-eight years of age, who had never borne children, eight years previously had observed an enlargement of the abdomen that had continued to increase gradually. At the time of her entrance into the hospital the abdomen measured forty-five inches in circumference at the umbilicus. There was no cachexia whatever, only the size of the tumor annoyed her. A positive diagnosis of cyst of the broad ligament was made, and six weeks ago thirty-eight pints of clear fluid were withdrawn. A careful bimanual examination showed that the cyst was situated in the right broad ligament. The patient left the hospital well several days later, and when she returned, after six weeks, no sign of the cyst could be detected by bimanual examination. The case was unusual only from the exceptionally large size of the cyst.

IV. PELVIC SARCOMA LIMITED TO THE CELLULAR TISSUE.—A woman, fifty-five years of age, the mother of a number of children, had suffered from an enlargement of the abdomen, accompanied by pelvic pains, which during the past two months had become exceedingly severe. The tumor was very tender to the touch, and was found to lie in the recto-vaginal space, pressing the vagina forward and downward and the rectum backward. It was tapped on two different occasions, and a thick, bloody fluid, readily coagulable, was withdrawn, with a few flecks of pus. The diagnosis lay between sarcoma with fluid contents and pelvic hematocele. After three weeks, the tumor slowly increasing in size in the mean time, without signs of septic infection, an opening was made through the vagina, and copious fresh coagula were discharged. The walls of the cavity were found to consist of irregular soft masses, which could readily be scraped out with the vaginal depressor. Microscopical examination showed it to be a round-cell sarcoma, with but little fibrous tissue. The temperature rose to 103° Fahr., and the patient died of acute septicemia on the fourth or fifth day after the operation. Post-mortem examination showed that the disease was limited to the cellular tissue in the recto-uterine space, neither the uterus, the ovaries, nor any of the other organs in the pelvic cavity being involved in the least. He had not been able to find a similar case recorded in medical literature, although sarcoma of the uterus and of the ovaries was not very uncommon.

Dr. W. R. Gillette remarked, with regard to the first case, that six weeks ago he withdrew from an abdominal tumor fluid which had the exact appearances of fountain water, and those present supposed it belonged to a tumor of the broad ligament, but it proved to be one of the ovary with a small pedicle. He had had a similar case a few years ago.

Dr. J. B. Hunter had seen several cases in which the fluid withdrawn from an abdominal tumor before its removal was perfectly clear, as in cases of cysts of the broad ligament, but which afterward proved to be cases of ovarian tumor.

The President thought that the usual turbidity of the fluid of ovarian cysts was due to either an acute or subacute inflammation of the lining membrane arising from pressure by surrounding organs. Where the cyst grew rapidly, and pressure did not exist, at least in great degree, the fluid was likely to be clear. This view was also entertained by the pathologist of the society and by other authors.

Dr. Gillette, referring to the two cases related by Dr. Munde, remarked that he had at present two patients under his care upon whom he hesitated to perform Taft's operation, although it would seem to be indicated by the subjective symptoms, mainly for the reason that, as in Dr. Munde's case, the operation so frequently failed to give permanent relief, and also because the symptoms apparently indicating the operation might pass away in the event of an assumption of new sexual relations in the patient's life.
This latter phase was illustrated by the following case: In the spring of 1882 a widow consulted the doctor for constant neuralgic pains in the pelvic regions, by which her life had been rendered miserable. She gave a history of having had two or three attacks of pelvic cellulitis some time previously, for which she had been treated by several physicians on the Pacific coast. All the treatment, however, had failed to relieve her of her persistent pain in either ovarian region. Her general appearance was that of a woman in good health and well nourished. Her menstruation, she said, was painful and irregular as to time, but pretty constant as to quantity. This had been her habit through life. She had never been pregnant. Upon examination, the pelvic organs were extremely sensitive, and there was considerable pain over either ovarian region upon pressure. There was so much adipose tissue that it was impossible to determine through the abdominal wall whether there was any tubal enlargement or not, and through the pelvic region it was utterly impossible to make any satisfactory examination of the condition. From her history, he presumed the case was one of pyo- or hydro-salpingitis; and his advice was that, as a last resort, Tait’s operation should be performed. She stated that, if her sufferings should continue as they had, she would not hesitate as she was perfectly miserable as she was. During the summer, however, she took a trip to Europe, and while on the steamer met a gentleman to whom she became engaged, and, on her return from Europe, they were married. From that time all pain disappeared entirely, and, so far as she knew or the doctor could ascertain, she was as well as any woman he had ever met. There was not the least degree of pain on examination, and the introduction of the probe into the uterus, which she could not tolerate previously, and which indeed at one time almost lighted up a cellulitis, was borne with perfect impunity. There was no tenderness over the ovaries, and there was no point of tenderness to be elicited anywhere, and nothing to indicate that there could be, by any possibility, any disease whatever of the pelvic organs.

This case, undoubtedly, was one not at all uncommon among widows—simply one of reflex irritation consequent upon ungratified sexual appetite. The lady herself, who was a very intelligent woman, did not hesitate to join the doctor in this his last diagnosis of her condition.

Another of the cases to which reference had been made, and which would seem to call for Battey’s or Tait’s operation, was that of a woman who had been a mistress, but who was now under a certain religious restraint. She had changed her sexual relations, her pelvic symptoms had developed, and she had hystero-spielepsy in addition to pains referable to the pelvis and ovarian regions. No enlargement of the tubes had been demonstrated in her case, but all her other sexual organs, so far as they could be examined, were in a highly hyperesthetic condition, and at times apparently almost in a state of inflammation. In the opinion of the speaker, this case was almost identical in many of its features with the other. The patient had formerly indulged in sexual excesses. She had been seen by several physicians, and it was a question with them whether an operation for the removal of the ovaries or tubes was justifiable or not.

These cases were either or both of them typical of cases heretofore operated upon according to Battey’s method, and there could be no question, probably, that, if the operation of Battey had been performed, and the ovaries removed, all pelvic symptoms might have disappeared as a matter of supposed natural consequence; but the fact that one of them had been cured by the resumption of a normal function was very interesting; and probably in many instances we ought to pause before recommending this operation to young or unmarried women on this account. He knew that reflex irritation from the male sexual organs produced strange phenomena, and the late Dr. Van Buren had attributed many of the nervous conditions and perturbations of men to ungratified sexual desire. There could be no question about it, that this ungratified sexual appetite created a most unfortunate series of phenomena in both sexes, and more particularly in the female than in the male; consequently it must always be estimated in considering such a serious operation as Battey’s or Tait’s. The modesty and native secretiveness of women would rarely assist us in such cases by a direct avowal or confession, and we ought in all cases to use every effort to determine the exact psychological state of unmarried women who were willing to submit to the severest surgical alternative that can be presented to them for a relief from pelvic pain or distress.

Dr. Mundé remarked that, since in Dr. Gillette’s case the patient recovered after marriage without treatment, it was an indication that the condition calling for Tait’s operation did not exist.

Dr. Gillette remarked that he did not make a positive diagnosis of salpingitis; he simply stated that there were all the subjective symptoms of that condition. He should agree with Dr. Mundé that, if with these subjective symptoms enlargement of the tubes could be recognized with certainty, Tait’s operation should be performed as soon as the patient’s consent could be obtained.

The President thought that, in justice to Mr. Tait, it should be said he did not advocate the removal of the tubes or of the ovaries in cases simply of a neuralgic or hysterical character; that his advice to do the operation was restricted to cases in which a physical change in the structure of the tubes could be recognized on examination. In such cases greater benefit had been derived from laparotomy than from any other means, and he resorted to the operation boldly. On the other hand, Dr. Battey, of Georgia, he believed, removed the ovaries largely for dysmenorrhoea, without reference to structural change or enlargement, and he did not doubt that it was to the too great tendency which had been shown by some to resort to Battey’s operation in cases of neuralgia of an hysterical character, and not to Tait’s operation, which was applicable to cases in which a structural change could be recognized, that exception had been taken. He recalled a case in which an operation for removal of the ovaries was done in the case of a patient suffering from pelvic pains and hysterical symptoms, and after the operation, although the pelvic pains ceased entirely, the mental symptoms at once became worse, and finally the patient had to be sent to an asylum for the insane.

Fibroid Tumor of the Uterus Removed by the Galvanic Cautery and by Excision.—Dr. Blanche McC. Emment presented the specimen. The patient from whom it was removed had suffered from hemorrhage and partial inversion of the uterus. Before the operation, however, the organ resumed its natural position spontaneously. After some days of preparatory treatment, with the assistance of Dr. Dawson, the galvanic-cautery wire was placed around the tumor as high up as possible, and the capsule was cut through. An attempt was then made to apply the wire still higher, and, while doing so, traction was made, as indeed it had been throughout, and the tumor unexpectedly became eucelated and was removed entire. This excellent result, although accidental, Dr. Emment believed could not have been obtained as conveniently by the use of the scissors. Enucleation was far more advantageous than excision, inasmuch as there was less danger of its being followed by haemorrhage, septiciemia, or a return of the growth.

Dr. B. F. Dawson thought that in this case the accidental result following traction upon the tumor after division of its
capsule by the galvanic-cautery wire suggested a method of operating which could be adopted in the future in similar cases. With regard to the President's statement, that he had found Thomas's scoop an excellent instrument with which to divide the capsule, the galvanic-cautery wire possessed the advantage of leaving a charred surface, from which hemorrhage and septic absorption were less liable to take place, and of leaving less of the capsule behind.

HENRY J. GAERGUES, M. D.,
B. F. DAWSON, M. D.,
FRANK P. FOSTER, M. D., ex-officio,
Committee on Publication.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held February 1, 1883, the President, Dr. R. A. Cleemann, in the chair.

ANALYSIS OF TWENTY-SEVEN OPERATIONS FOR THE RESTORATION OF THE LACERATED CERVIX UTERI, WITH SPECIAL REFERENCE TO THE EFFECT ON STERILITY AND LABOR.—DR. B. F. BAER

read the following paper:

In the discussion which followed the reading of Dr. Playfair's paper on "Trachelorrhaphy, or Emmet's Operation," before the Obstetrical Society of London, on March 1, 1882, Dr. Herman, in the course of his remarks, said that "the American literature on the subject consisted mostly of general statements. Few writers had published cases, and the cases were mostly complicated ones." There is some force in these words. But, to avoid a monotonous repetition, it is desirable only to publish such as are strongly illustrative of the class to which they belong, or such as bear directly upon any point which may be under discussion.

In the "American Journal of Obstetrics" for January, 1883, Dr. P. J. Murphy, of Washington, D. C., makes some "Observations on the Effects of Trachelorrhaphy on Fertility and Parturition," and comes to the conclusion "that repair of laceration of the cervix uteri is usually followed by sterility." Now, there is no doubt of the truth of this statement so far as it goes, but I think he ought rather to have said that, in those cases in which sterility followed the operation, that condition also preceded the repair of the cervix in the majority of instances, either as a result of the laceration itself, or of its effects on the uterus and its appendages, and that the operation was not the cause of the sterility, but that it simply failed to cure it.

The only way to arrive at anything like a correct conclusion on this subject is to take a number of cases (it need not be large) and analyze them, and this I purpose doing with mine.

Of the twenty-seven patients upon whom I have done the operation, six were either widows, or had reached or passed the menopause, and must therefore be excluded from the analysis. This leaves twenty-one cases to be reported upon in this inquiry. Of the twenty-one patients, thirteen had been sterile from five to sixteen years previous to the operation, and I think, for reasons which I will give farther on, that they ought also to be classed as beyond the probability of becoming pregnant. In the remaining eight cases, pregnancy had occurred within five years, but had resulted in abortion in five. In twelve of the twenty-one cases, from one to five abortions had occurred in each subsequently to the occurrence of the laceration. This gives abundant proof of the ill effects of the lesion and its results—subinvolution, chronic hypertrophy, cellulitis, oedema, etc.—on fertility.

Is the assertion, that sterility usually follows as a result of the operation, correct? I do not think so; provided, of course, that the operation was properly done, that the os was not made too small, and that immediate union followed the coaptation of the parts, so that there was left the minimum amount of cicatricial tissue to interfere with the normal resiliency of the cervix.

The former abortion occurs, as a rule, the greater and more persistent will be the histological changes in the uterus and its appendages, which finally result in sterility.

The majority of cases in which the operation has been done have been of long standing, because the operation is new, and there were many old cases of so-called "ulceration" with chronic hypertrophy, waiting ready to be experimented upon with this as they had been before with many other old and new remedies.

Is this last new remedy followed by any greater success than the old in the reduction of the size of a large uterine body which has become hard and fibrous from connective-tissue hyperplasia? I think not; and hence its failure to cure sterility of long standing from this cause. But, for the cure of certain cases of hypertrophy of the cervix, inflammation, ectropion, and abrasion of the mucous membrane, with their local and remote symptoms, and possibly, even probably, preventing epithelium, and in the more recent cases for the cure of subinvolution, abortion, and sterility, the operation is an immense stride in advance of the old way of destroying the tissues of the cervix by amputation, or by the application of the hot iron or the potential cauteries. It is an advance, because it restores the cervix instead of destroying it.

The following case proves, I think, that abortion may result from laceration of the cervix, although none of the usual inflammatory consequences of the lesion are present.

CASE I.—Mrs. M. L., aged thirty, consulted me in January, 1881. She was delivered of her first child two years previously. The labor was rapid. The child was fully developed and vigorous. There was nothing unusual in the puerperal period, and she seemed to be well. Ten months after the birth of the first child she became pregnant again. Between the second and third months of gestation the product of conception was expelled with little pain, but it was followed by severe hemorrhage. Within three months she was again pregnant, and aborted at about the same time and in the same manner as previously. This was followed within six months afterward by a third pregnancy, and abortion under similar circumstances. The last occurred about two months before she consulted me. She had absolutely no symptoms of uterine disease, such as leukorrhoea, menorrhagia, and the pain which always results from congestion and hypertrophy of the uterus; and expressed herself as feeling as well as ever she had in her life. There was no evidence whatever of syphilitic infection, either in the patient herself or in her husband. They are both robust and well developed.

EXAMINATION.—The perineum and vagina were normal. The uterus was in normal position; it was neither congested nor enlarged; but the cervix was lacerated on the left side to a point beyond the vaginal attachment. Apparently approaching and involving the fibers of the internal os. On the right side there was a mere fissure only. There was no hypertrophy, eversion, or abrasion of the mucous membrane. The sound passed to a depth of two inches and a half. I expressed the opinion that the lacerated cervix and the abortions stood in the relation of cause and effect; and I advised an operation for the restoration of the torn cervix.

On March 10, 1881, I demaded the surfaces, being careful to remove very little tissue, and to freshen the edges as far up toward the internal os as possible. I then placed six carbolized cautier sutures, and clamped them with a shot. I used the gut suture here in preference to the silver wire, because, as the cervix was not large, and the tear principally unilateral, there
would not be much tension, and for the additional reason that I especially did not want any cutting of the tissues by the sutures, which is more apt to occur when wire is used. Another advantage of gut suture is that the line of union need not be disturbed by the removal of the stitches. On the seventh day after the operation I inspected the cervix through Sims's speculum, and found the sutures all in situ, though they were partially absorbed. Union was perfect. Two days afterward the shot were lying loose in the vagina. There had not been the slightest discharge from the united surfaces since the operation.

On June 3, 1881, the patient reported that she had not menstruated for seven weeks, and there was every indication that she was pregnant. A week later I was requested to visit her. I was much chagrined to find, when I arrived, that she had aborted. This was very discouraging, but I found some comfort in the character of this abortion. More pain attended the expulsion, and less haemorrhage followed it than on the previous occasions. This I ascribed to the restoration of the symmetry of the cervix and its better retractive power.

On October 9, 1881, she reported that she was about two months pregnant, and feeling well; and on May 7, 1882, she was delivered at full term of a fully developed, healthy boy, after a perfectly normal labor of six hours' duration. Examination two months afterward revealed not the slightest laceration of the cervix. The mother and child are both well.

Case II.—Mrs. M. R., aged twenty-one years, consulted me in May, 1878. She had been delivered eight months before of her first child; the labor, being tedious, was terminated with the aid of the forceps. The puerperal period was also tedious, and she had ever since been troubled with pain in the hypogastric and lumbar regions, together with a profuse leucorrhoea. Coition was painful, and followed by slight haemorrhage. She was anaemic, and had lost flesh.

Physical Exploration.—The perineum was slightly lacerated and the vagina relaxed. The cervix uteri was pressing low down on the pelvic floor, and lacerated bilaterally, but to a greater degree on the left than on the right side. The tissues were soft from engorgement, and the mucous lining of the cervical canal greatly hypertrophied, everted, and abraded of its epithelial covering, so that it bled on the slightest touch. The uterine body was likewise congested and tender. The sound gave a measurement of less than three inches.

I treated this patient locally and constitutionally for almost a year, with marked general improvement, and, although the local condition would improve, the benefit was only temporary. On April 30, 1879, I did the operation for lacerated cervix, placing seven silver sutures. Perfect union resulted. Three months after the operation she became pregnant, and was delivered spontaneously at full term. The labor was so easy that delivery occurred before the arrival of the physician. Two months after the labor she called at my office, at my request, and I found the cervix healthy, although there was a very slight fissure on the left side. She stated that she had been well since the operation.

Case III.—Mrs. A. B., aged thirty-four years, was sent to me in July, 1880. She had had eight children, the youngest of which was six months of age. She stated that she always menstruated during lactation, and became pregnant when her children were about eight months old. Since the birth of the last child she had had metrorrhagia every three weeks, lasting one week, and a profuse leucorrhoea for years. She complained of pain in the lumbar region, with a heavy dragging sensation in the pelvis and on the top of the head. She was emaciated, and so pale that she appeared bloodless. She had become hysterical.

Touch.—The perineum and vagina were very much relaxed. The cervix uteri was far back, and presented a nodular surface, the result of three deep rents in its tissue, one of them extending through the center of the anterior lip, flush with the vaginal junction. There was marked ectropion of the mucous membrane, with abrasion. The body of the uterus was anteverted, and only slightly larger than normal.

I placed this patient upon the "rest treatment" of Dr. S. B. Weir Mitchell (modified somewhat to suit the circumstances), in addition to the necessary local treatment. Her improvement was very marked, and, on October 10, 1880, three months after she first came under my care, I operated for the laceration, and secured immediate union.

Under the date of October 27, 1881, a year from the date of the operation, I find this note in my case-book: "Returns today, at my request, for examination. She has improved so much in appearance that I scarcely knew her, and she states that she has been well since a short time after the operation. The cervix is perfectly normal, and gives no evidence that an operation has been made,"

I recently received from my friend, Dr. William L. Taylor, the following note concerning this lady:

"Dear Doctor: In answer to your inquiry regarding Mrs. B., I will state that she was confined six weeks ago. The labor was natural, and, if it differed in any way from her former labors, it was more rapid. I examined the cervix to-day, and found the external os patent, but no laceration."
REPORTS ON THE PROGRESS OF MEDICINE. [ N. Y. MED. JOUR.

CASE V.—Mrs. M. R., aged thirty-nine, consulted me in the fall of 1880. She had had six children, the last one thirteen years before. Her labors were all normal, so far as she knew, except the last. This was complicated by a malposition. The forceps was applied two hours before the delivery of the head, and great traction effort was necessary. The child was so injured by the forceps that it died on the third day after delivery. The patient was unable to be out of bed for nearly three months afterward, and the bloody lochia continued during two months. She had suffered from menorrhagia ever since, and recently from metrorrhagia every two weeks, at times amounting to "almost a flooding." In the intervals between the hemor-

rhagies she had a constant and profuse mucous leucorrhea. She complained of a deep-seated pain in the pelvis, "saving" in character, with pain in the sacral and lumbar regions and across the shoulders. Covilion could not be tolerated, because of the pain it induced and the hemorrhaiges which resulted.

Examination.—The perineum showed an old laceration of slight extent, and within an inch of the vaginal orifice the finger came upon a large mass of tissue which filled and distended the tube. It was hard and nodular around its border, but softer and rather friable in its center; and it bled on the slightest touch. It gave me, at first, an impression of epithelioma, and I could readily detect that the cervix was bilaterally lacerated down to the vaginal attachment. The body of the uterus was hypertrophied, indurated, retroverted, and slightly fixed from contraction of the broad ligaments. Through the specimen the cervix was seen to be lacerated, as the finger had indicated, and it was seen also that the softer tissue, which occupied the space between the separated lips, was redundant mucous membrane, which seemed to have united from side to side, leaving a very small opening in the center, corresponding to the external os. This tissue was dotted all over its surface with whitish spots—Nabothian cysts. The sound passed to a depth of less than four inches, and showed the uterine cavity to be rugous—vegetations of the endometrium. I now punctured the retention eyst, and found that the redundant tissue between the torn and separated lips was riddled with them. So much hemorrhaige resulted from the scarification that, to check it, I was finally compelled to tampon the vagina. On the next day I removed the tampon, and found the mucous membrane much reduced and less con-

gested.

I treated this lady during a number of months for the purpose of relieving symptoms and preparing the parts for an operation on the cervix. The hypertrophy and congestion of the mucous membrane of the cervix and uterine cavity were considerably reduced, the metrorrhagia and leucorrhea diminished. The uterus became more mobile, and tenderness subsided; but the parenchyma of the cervix and body of the uterus remained sclerotic and unreduced in size.

On February 10, 1881, I closed the rent after denuding the surfaces and dissecting away a large amount of ciliated tissue from the sides and angles. I placed eleven silver sutures. Considerable difficulty was experienced in passing the needles through the dense and tough cervix, and I broke and bent several before I succeeded in placing all the stitches. The surfaces did not unite as readily in this instance as is desirable, but union was finally established by granulation, resulting in the formation of a good cervix.

This patient has been entirely relieved of the leucorrhea and pain of which she complained, but she still has an occasional menorrhagia, and the body of the uterus remains large and hard, the sound entering three inches and a half. As was to be expected under these circumstances, she has remained sterile, but certainly not as a result of the operation.

Dr. Murphy further says: "I fear I shall never arrive at

that perfection where it will be given to me to appreciate why a laceration of the cervix, by being repaired, will probably prevent cancer of the womb."

I do not wish to discuss this subject here, as I am preparing a special paper upon it, but I would like to say that, if we believe that cancer may develop in consequence of the changes in the circulation and nutrition, which necessarily follow when the cervix is torn—and it seems to me that one need not have arrived at perfection in the art of appreciation to believe that cancer might develop in a field such as was presented in Case IV previous to the operation—then restoration of the organ ought to prevent cancer.

He also concludes "that the character of the labor is unusually severe and protracted, and that, in a large percentage, laceration occurs a second time."

That this statement is too sweeping is abundantly proved by the cases I have record. I can believe, where pregnancy has happily followed the operation in a case of long standing, in which the cervix is sclerotic from connective-tissue hyperplasia, and cicatrical from non-occurrence of immediate union, that the first stage of labor might be tedious, and that laceration might take place. But, suppose laceration does occur in some cases, is that sufficient reason to deprive the patient of the benefits which usually accrue from the operation independent of pregnancy?

Not long ago I did the operation for the restoration of a laceration of the perineum, which extended full an inch and a half up the recto-vaginal septum, on the person of a lady fifty-one years of age. The laceration occurred twenty-six years before with a severe forceps labor. She had been debarred from the society of her friends, and made lonesome to her husband as well as to herself all these best years of her life. In answer to my inquiry why she had not sought relief long before, she replied that she had done so, but that she had been advised to wait until after the menopause, for fear that, in the event of another parturition, the parts would relaxate! Comment on such argument as that is unnecessary.

The comfort which this lady has enjoyed since the rectum and perineum have been restored causes her to feel far from kindly toward the gentlemen who advised such conservatism.

I have recently delivered two ladies on whom the operation for lacerated perineum was done about three years ago, one by Dr. Goodell, and the other by myself. Relaxation did not occur in either.

(To be concluded.)

OPHTHALMOLOGY AND OTOTOLOGY.

BY CHARLES STEEDMAN BULL, M. D.

LECTURER ON OPHTHALMOLOGY AND OTOTOLOGY IN THE BELLEVUE HOSPITAL MEDICAL COLLEGE; SURGEON TO THE NEW YORK EYE AND EAR INFIRMARY; OPHTHALMIC SURGEON TO ST. MARY'S FREE HOSPITAL FOR CHILDREN, AND TO THE NURSERY AND CHILD'S HOSPITAL.

OPHTHALMOLOGY.

(Concluded from page 25.)

INTRAOCULAR TENSION IN THE WHITES, HALF-BREEDS, NEGROES, AND NATIVE INDIANS OF SOUTH AMERICA.—Moira-Brazil ("Annales d'Oculistique," March-April, 1883) presents a preliminary note of his investigations into this subject. In the black race, the hydrostatic pressure of the eyeball, in the physiological state, is greater than in the half-breeds, and still greater
than in the white race. In the latter, the first degree of glaucomatous tension, in general, corresponds to the physiological tension in the negro race. Thus, when the increased tension (T + 1) is from 10 to 15 per cent, in the white race, it is from 45 to 60 per cent, among half-breeds, and from 45 to 90 per cent, among blacks. The observations upon Indians were confined exclusively to persons under thirty-five years of age, who were all hypermetropic.

One of the striking facts developed in these observations was the greater extent of the visual field for colors, especially for green, in these same individuals. The field for green often coincided with the field for red. The excess of tension here spoken of is, up to a certain point, without functional injury; but note the lesion would be unmasking a predisposition to glaucoma, or even as being the prodromal period, which may be prolonged more or less, according to age and race, without it being possible to establish a line of demarkation between this stage and a true glaucomatous one.

On the Value of Eye Symptoms in the Localization of Cerebral Disease.—Nettleship ("British Medical Journal," Dec. 2, 1882), in a paper read before the Ophthalmological Section of the British Medical Association, offers some interesting points for general discussion. Under the head of visual and ocu-lo-sensory disturbances he states that double optic neuritis very seldom helps us to decide where a brain lesion is. The occurrence of optic neuritis with meningitis points to the meningitis being basal; it is rare in meningitis of the convexity. Unilateral papillitis sometimes occurs in cases of coarse brain disease, and has some localizing value, generally coming on, so far as recorded cases tell, in the eye opposite to the lesion. It is of importance that all cases should be carefully observed and recorded; and it would be well to include, as possibly bearing on the subject, cases in which the papillitis, though eventually double, takes place in one eye long before, or much more severely than, in the other; also cases of double and equal papillitis, where sight is much more affected in one eye than in the other. In the present state of knowledge it would be seen, from what has been said, that papillitis, with other symptoms of brain disease, tells us something of the seat of the brain lesion if it be single, if the second eye do not suffer until after a considerable interval, or if papillitis in one eye be accompanied by failure of sight without immediate change in the disc of the other. Nettleship believes that atrophy following pressure on the chiasm, whether by tumor or by fluid distension of the third ventricle, presents nothing pathognomonic either in its course or appearance. It is certainly possible in some, though by no means in all, cases of atrophy not preceded by papillitis, to distinguish between spinal atrophy, where the disc is often opaque and grayish, and the lamina cribrosa concealed, and atrophy secondary to injury, pressure, or destructive inflammation far above the eye, in which the lamina cribrosa is often exposed, the disc somewhat cupped, and its color less gray than yellowish. But these differences are far from constant, and give no aid in localization of brain disease. Nor is it always possible to say whether atrophy has been preceded by papillitis or not. Color-blindness does not seem to occur in any constant relation, either to loss of vision or loss of visual field, in optic atrophy. Some cases have recently been recorded which seem to point to the consciousness of color depending rather on the special endowment of some part of the brain than on any differentiation of the retinal or optic neural structures. Color-blindness is nearly always very marked in optic atrophy associated with ataxy, yet it is probable that in these cases the changes begin at the ocular end of the nerve. Failure of color-perception, in its bearing on cerebral localization, needs further study.

In regard to those cases of pseudo-glcoma with brain symptoms in children, it is very desirable to know what changes, if any, occur within the skull. If meningitis occur, is there anything unusual in its seat or nature, and why does the child show this peculiar eye disease instead of suffering from double optic neuritis? The questions of pyemia and of cerebral thrombosis have also to be considered in connection with such cases.

In regard to temporal hemianopia, the symptom has in rare cases been proved to be due to tumor at the anterior part of the chiasm. The fact that homonymous hemianopia occurs from destructive lesion of one optic tract demonstrates the semi-decussation of the optic nerves at the chiasm in man. Several cases in which the lesion has involved the region of the corpora geniculata and the posterior part of the optic thalami are also on record. It has been shown further, in several cases, that lesions of the cortical or subcortical structures in the region of the angular gyrus and occipital lobe may produce homonymous hemianopia. Ferrier suggests that in tract hemianopia the loss of field may be expected to come quite to the fixation point, while in cerebral hemianopia it may be expected to stop short of the fixation-point by several degrees, leaving thus a smaller area of central vision perfect.

In homonymous hemianopia it is not uncommon to find also some peripheral restriction of the remaining half of each field; this may be greater in one eye than in the other, but it does not seem that the eye with the greater restriction always bears the same relation to the lesion. The hemianopic loss of field, moreover, is by no means always equal in the two eyes; and this inequality, like the peripheral limitation mentioned, does not seem to stand in any constant relation to the site of the lesion. The rarity of decided atrophic changes at the optic discs, in cases of homonymous hemianopia, even of long standing, points strongly against the tract being the seat of the lesion. Pathological evidence is beginning to accumulate in favor of a cortical visual center, and of its being seated in or about the occipital lobe. Nettleship considers it very important, in reference to localization, to note the state of the pupils in all cases of damage or loss of sight from brain disease. Loss of reflex pupillary action indicates damage not higher up than the corpora quadrigemina, while blindness with active pupils points to disease in the cortex or subcortical structures.

Ophthalmometric Researches on the Astigmatism of the Cornea in Scholars from Seven to Twenty Years of Age.—Nordenson ("Annales d'oculistique," March-April, 1883) has made a careful study of this subject, his report being illustrated by numerous tables. He formulates his conclusions as follows: 1. In eyes free from astigmatism the radius of curvature of the cornea is the same for both eyes; the difference is not generally measurable; and this is in accord with the writings of Donders, Mahtner, and others. 2. In children who are free from astigmatism, the visual acuity is, as a general rule, greater than the normal by one and a half time. 3. In emmetropes, nine out of ten present a measurable amount of astigmatism. The proportion of astigmatic persons is greater among hypermetropes, and still greater among myopes. 4. Among the whole number of children (two hundred and twenty-six), sixty-nine had an astigmatism of at least one dioptre in one eye, which Nordenson thinks is sufficient to bring to the notice of the relations of the children, so that the children might be sent at once to an oculist as soon as symptoms of myopia and asthenopia manifested themselves. 5. Four of the two hundred and twenty-six children had an astigmatism greater than D. 1-50, and should be provided with spectacles at once. 6. The normal acuteness of vision is compatible with a corneal astigmatism of at least a dioptre and a half (D. 1-50). 7. As a general rule in young people, the crystalline lens plays a part in the correction of astigmatism. 8. These observations seem to confirm the statement of Javal that astigmatism predisposes to myopia. Among the
nine scholars that were free from astigmatism, there was not a single myope; while among the thirty-two myopes none were free from astigmatism, and two thirds of them had an astigmatism of at least half a dioptre (D. 0·50).

Abscess of the Frontal Sinus; Cure.—Notta ("Rec. d'ophtal.," March, 1883) reports a case of this nature in a woman aged sixty-four. She was first seen on November 1, 1882, having applied for surgical interference for a small tumor at the inner angle of one eye. She had been subject to catarrhal colds in the head for fifteen years, and of late the discharge from the pituitary membrane had had a fetid odor. She had occasional pain in the forehead, especially just over the left eye. On examination, a tumor was seen, just above the inner canthus of the left eye, as large as a pigeon's egg. Pressure on this tumor caused it to disappear, while a stream of fetid and greenish pus flowed either from the left nostril anteriorly, or from the posterior nares into the mouth. An examination of the supra-orbital arch on the left side shows a depression at the site of the tumor, due to the absorption of the anterior wall of the frontal sinus. An incision about fifteen min. long was made parallel to the orbital margin and just above it, and the internal wall of the frontal sinus was scraped with a rasp. The cavity was then stuffed with charpie with a solution of zinc chloride, and over this was placed a carbonized dressing. At the end of two days the charpie was removed, and twice a day the cavity was injected with carbonized solutions. By the last of December the wound had completely closed.

Two New Cases of Cavernous Angiomata of the Orbit, with Remarks.—Panas ("Archives d'ophthalmologie," Jan.–Feb., 1883) reports two cases of cavernous angiomata of the orbit, one in a young woman of twenty-three, and another in a boy of ten. The first case corroborated the views held of the intranursular seat of the tumor in the funnel formed by the recti muscles. In this case it was rendered indubitable by the abnormal insertion of the ocular muscles on the surface of the tumor. The eyeball was pushed away, and disorganized by the tumor insinuating itself between the globe and the muscles and closely surrounding the former. The frequent coexistence of a simple periorbital angiomata with angiomata of the orbit is also confirmed by both cases. The presence of pigmented elements, mentioned by Horner, is also confirmed by the first case.

Paralysis of the Associated Movements of the Eyes. —Lavineau ("Archives de neurologie," v. 14, March, 1883) in his paper has studied the paralyses of: 1. Horizontal parallel movements; 2. Vertical parallel movements; 3. Movements of convergence; 4. Movements of divergence. He finds that associated paralyses are frequent in disseminate sclerosis of the brain substance and spinal cord, but that they are usually incomplete. One reason why they are easily overlooked is that diplopia is very often absent, and that it hardly ever exists when the paralysis is old. In disseminate sclerosis, conjugate paralysis is almost always accompanied by nystagmus. In the majority of cases the latter, even when connected with infantile amblyopia, is caused by a lesion of the nuclei of the gray substance which precede over binocular associated movements. Hence it is not surprising that the nystagmus coincides with paralysis of these movements. When the lateral conjugate paralysis is slight, its diagnosis is sometimes difficult. The diplopia is not characteristic, and the ocular movements are sometimes but very slightly modified. When nystagmus is present, the oscillations have no very great significance when they are developed in the line of action of the paralyzed muscles; but, when they exist in the contrary direction, they are of greater significance. The presence of a hemiparesis of the muscles of the opposite side, and especially of an alternate paralysis of the face and limbs, would call attention to the conjugate paralysis. The paralysis of parallel vertical movements is not so complex as would at first appear. If it were confined to one eye, it might be explained by a partial lesion of the nucleus of the third pair, involving all the muscles of the eye innervated by this nerve, except the levator palpebrae and the iris. According to the observations of Hensen and Volkers, this lesion should be in the posterior part of the nucleus, near the superior angle of the fourth ventricle. The absence of paralysis of the internal recti for lateral movements is explained by the existence of the filament sent from the nucleus of the sixth nerve to this muscle; and in this fact is found the confirmation of the double innervation of the internal recti (sixth pair for lateral or external motion, third pair for movements of convergence).

The paralysis of movements of divergence is essentially characterized by a slight homonymous diplopia, existing in all directions, without notable modification of the separation of the double images for a corresponding distance. The persistence of the diplopia in all parts of the visual field, and especially in its upper part, and the absence of obliquity of the double images, ought to prevent a diagnosis of paralysis of the fourth nerve, although the error is frequently made. In considering its etiology, we should include among the causes a lesion of the two nuclei of the sixth pair. This form of diplopia seems to be habitually connected with a condition of vertigo. Recent works seem to render almost certain the existence of a special nerve, called the nerve of space, annexed to the auditory nerve, lesion of which produces the vertigo of Ménière. Our ideas of space are gained not only by hearing, but also, and especially, by sight. We acquire the idea of a third dimension, to which that of space is closely allied, by the movements of convergence of the eyes. These considerations of physiological order favor the existence of a center of co-ordination of the movements of the eyes for convergence of the axes, located in the cerebellum.

Erectile Tumor of the Eyelids.—Richet ("Rec. d'ophtal.," Jan., 1883) reports a case of this kind in a child eight months old. The tumor was as large as a filbert, and occupied two thirds of the upper lid, extending as far as the oculo-palpebral furrow. It involved both skin and mucous membrane. It increased in size when over the child cried. It diminished under pressure of the fingers, but increased in size as soon as the pressure was relieved. Richet determined to treat the case by coagulating injections of the perihelum of iron, using an absolutely neutral solution and diluted seven or eight degrees, in order to produce simple coagulation. There is no record of the ultimate result.

The Treatment of Trachoma of the Conjunctiva.—Unterharnscheidt ("Klin. Monatsschr. f. Augenheilk.," Feb., 1883), is looking round for some means of relieving, if not of curing, cases of chronic conjunctival trachoma, after having run through the entire armamentarium of the ophthalmic surgeon, has, in a sort of despair, sought relief in the galvano-caustic method for those cases of papillary granular proliferations. He thinks the danger of injury by this operation is much less than by the use of the sharp spoon or knife, for with the loss of substance a slough is also simultaneously produced, which completely covers the loss of substance and protects it from external noxious agencies. The application of the heated plate is easy, causes but trilling and momentary pain, and renders anesthesia unnecessary. The agent acts rapidly, and destroys more surely than any other method the micrococci, which have been demonstrated to exist in trachomatous conjunctiva, and which by contact will produce trachoma in a healthy conjunctiva. Unterharnscheidt has hitherto used the cautery only upon the conjunctiva of the upper lid.

Four Cases of Dermoid Tumor of the Eye. —Vassaux ("Archives d'ophalmologique," Jan.-Feb., 1883) reports four
cases of dermoid tumor in the region of the conjunctivo-ornear limbus, and, from an examination, draws the following conclusions: 1. The dermoid tumor has all the histological characteristics of true skin. 2. A dermoid tumor is produced by an invasion of the eyelid at some point of the conjunctiva, ocular or palpebral. 3. The cause of this invasion is a preliminary and temporary adhesion between the annular and the ocular vessels.

**Myxo-fibroma of the Optic Nerve.** — Véron ("Rec. d'ophtal.," Jan., 1888) reports a case of this nature in a young man of eighteen years, which had existed for three years. The eye was protruded for about three quarters of its antero-posterior diameter from the orbit, and the eyelids were widely distended. The exophthalmus was outward as well as forward, and the mobility of the eye was limited, especially inward and upward. The media were clear, the pupil sensitive. There was a high degree of hypermetropia, and atrophy of the optic disc. On examining the orbit, a tumor could be felt deep under the suprachiliary border, which seemed to be cylindrical and to surround the optic nerve. It was resistant, smooth, movable with the eyeball, and not adherent to the orbital walls. There was neither bruit nor pulsation. The eyeball and tumor were excised together, and an examination confirmed the diagnosis as to its being a tumor of the optic nerve. Its nature proved to be myxofibromatous.

**Neurasthenia Asthenopia and so-called Anesthesia Retinæ.** — Wilbrand (Archiv. für Augenheilkunde, xii, 2) in this paper proposes to show: 1. That in neurasthenic patients, in addition to asthenic troubles, there will also be found all the grades or varieties of signs pointing to so-called retinal anæsthesia. 2. That these appearances in the nervous apparatus of vision may all be explained in the same way as the great number of all the other analogous symptoms in other parts of the body of the same patient. 3. That, consequently, it is perfectly untenable and troublesome for the comprehension of the so-called retinal anæsthesia to regard it as a pathological appearance existing in and alone for itself.

**A Rare Case of Unilateral Retinitis Albiníntochra observed in a Patient with but one Kidney, situated on the Corresponding Side, and the Seat of Parenchymatous Neuritis.** — Véron ("Rec. d'ophtal," March, 1888) reports the following rare case in a Spaniard, aged forty-three, who had had most of the subjective and objective symptoms of parenchymatous neuritis, and in whom the right eye remained absolutely intact throughout the entire course of the disease. In the left eye there were the usual yellowish-white masses of exudation in the retina, beneath the disc in the region of the macula, and between the latter and the disc. There were numerous punctate hemorrhages, and some larger extravasations. Vision was not much affected when the patient first came under observation, but subsequently was almost entirely lost. After he had been under treatment about six weeks, the vision improved almost to the normal standard, and there was a considerable diminution of the retinal exudation. He subsequently, however, grew very much worse, the vision was again nearly lost, and the patient died in about ten weeks from the time that he first came under observation. At the autopsy the right kidney was found to be entirely absent, there being not a trace of kidney, artery, vein, or ureter, though the super-renal capsule was present in its accustomed place, and was of normal size. The place ordinarily filled by the kidney was occupied by a portion of the right lobe of the liver, enormously hypertrophied. The left kidney was in its normal position, was considerably hypertrophied, and presented the characteristics of the large, white, parenchymatous neuritis.

**Otoology.**

Results of the Division of the Acoustic Nerve, with a Discussion of the Significance of the Semicircular Canals for the Bodily Equilibrium.—Beechrow ("Archiv. für die gesamten Physiologie," xxx, 7 and 8) publishes the results of his investigations upon the above subject in a long and interesting article. He draws the following conclusions: 1. Unilateral division of the acoustic nerve in dogs produces forced movements in the form of revolutions round the longitudinal axis of the body toward the operated side, with the same characteristic peculiarities (deviation of the eyes, nystagmus, rotation of the head and trunk, etc.) as occur with unilateral destruction of the olivary bodies, or injury of the central gray matter in the postero-lateral part of the third ventricle, or by division of the cerebellar peduncles. 2. These forced movements of rotation appearing after division of the acoustic nerve, as in all other cases, are maintained almost uninterrupted only for a limited time immediately after the operation; later they appear paroxysmally, the paroxysms being interrupted by periods of rest, during which the animal lies in a forced position on the side corresponding to the lesion. In time the rotatory movements cease, being replaced by circular movements, generally toward the operated side, which are accompanied by distinct disturbances of equilibrium, which are manifested by the continual tendency of the animal to fall toward the side of the lesion. 3. All these symptoms must be regarded as reflex, since they are also met with in animals in which the cerebral hemispheres have either been destroyed, or have been rendered functionally incapable by narcosis. 4. There is, however, no doubt that the presence and the unimpaired condition of the cerebral hemispheres exert a certain influence upon the symptoms occurring after division of the acoustic nerve, since the involuntary movements are thus increased and excited. Only in this way can be explained the perceptible diminution of the characteristic movements of the animals after destruction of the cerebral hemispheres. 5. In the higher animals a simple destruction or removal of the frontal or parietal lobe for a considerable extent suffices to attain the desired effect. 6. After bilateral division of the acoustic nerves the animals show great disturbances of equilibrium, which are seen in the absolute inability to walk or stand, with entire absence of paralysis of the extremities. 7. The symptoms which appear after division of the acoustic or of the destruction of the semicircular canals are directly connected with each other, as from the loss of function of the operated canals, as also by the uninterrupted normal irritation of the uninjured canals, which continues to give rise to certain impressions, and to transfer these by reflex action to the motor tracts. The lack of harmony thereby resulting in the impressions proceeding from the destroyed and the uninjured canals extends to the centers of consciousness, and produces there a powerful reaction in the form of a feeling of vertigo, which acts in a manner to increase the motor disturbances, and is probably one of the important factors in exciting the involuntary movements. 8. This view can also be extended to the origin of those disturbances of motility which appear after injury of one of the three peripheral organs which are connected with the maintenance of the equilibrium—the semicircular canals, the central gray matter of the third ventricle, and the olivary bodies of the medulla oblongata. 9. Golz's hypothesis in regard to the variation in pressure of the endolymph explains sufficiently the functional exercise of the canals as a peripheral organ, which is directly connected with the maintenance of equilibrium, although it as yet needs positive demonstration. 10. The semicircular canals are organs which not only aid in maintaining the equilibrium of the head, but of the entire body. At the same
time they stand in very close functional connection with the function of the ear. 11. The influence of sound impressions upon the movements and the condition of equilibration of the body is probably exerted through the medium of the semicircular canals.

**Perforated Bone Growth in the External Auditory Canal, the Result of Long-continued Subjection to Removal by Snare: Microscopic Examination.**—Cocks and Minor ("Arch. of Otology," xii, 1) report a case of this nature in a man, aged twenty-eight, following an otterhorne of twelve years' duration. Two bony tumors were removed by the snare. The larger one was an irregular cylindrical mass, with a convex upper surface of comparative smoothness, an irregular, nodulated surface, and a roundish outer extremity, and a smooth articulart concavity on its inner end. It measured 15 mm. long, 10 mm. wide, and 7 mm. thick. The smaller tumor was an irregular prismatic mass, on the outer surface of which was a smooth, convex articulart surface, corresponding to the concavity of the larger bone. It measured, transversely, 6.5 mm.; longitudinally, 3.5 mm.; vertically, 4.5 mm. Both tumors were hard, and covered by a dense periosteum, which adhered closely to the smooth surface. The entire mass consisted of perfectly formed bone-tissue with beautifully marked Haversian systems. These osteomata undoubtedly arose from masses of granulation tissue, associated with inflammation of the middle ear. Osteoblasts from denuded bone, falling upon granulations, found a nidus for growth and reproduction. Minor offers, in explanation of the separate bones with articulating surfaces, the theory of the ossification of two contiguous granulation masses, motion between which was furnished by the movements of the canal, incident upon motion at the temporo-mastoid articulation.

The Influence Exercised by the Treatment of One Ear upon the Other Ear.—Eitelberg ("Zeitschrift für Ohrenheilkunde," xii, 2 and 3) formulates his conclusions upon the above subject as follows: 1. In many cases the treatment of one ear causes an improvement in the hearing power of the other ear, which has not been treated, while a diminution of the hearing power is very rarely produced. 2. The greatest difference in favor of the improvement of hearing in the ear not treated occurred in cases of one-sided acute or chronic otitis media purulenta, with defective hearing in the other side. 3. In disease of both ears, when only one ear was treated, an improvement very often appeared in the other ear, not only in respect of the hearing power, but also in respect of the existing subjective noises. 4. In many cases an improvement, and even complete restoration, of the hearing power appeared in the ear not treated, not immediately upon the treatment of the other ear, but some time after. 5. In some cases, after a certain time had elapsed, the improvement in the hearing subsided and the ear returned to its former condition.

**The Examination of Ears by Means of the Tuning-Fork.**—Emerson ("Arch. of Otology," xii, 1), after an examination of a large number of persons with normal hearing, draws the following conclusions: 1. Reliance on the statements of patients in regard to the loudness of tuning-forks, as a test in ear troubles, will lead to error, unless account is taken of the fork used. As a rule, in normal ears high notes are heard louder through aerial conduction, and low notes louder through bone-conduction. This is true also, to a limited extent, in diseased ears. 2. The relative duration of aerial and bone-conduction is a better test. In normal ears, in all cases, the tuning-fork is heard longer through air than through bone, the proportion being greater for high than lowest notes; and for the middle C (c') it should be heard about twice as long through air as through bone. Any marked departure from this indicates disease. 3. In external- or middle-ear disease this proportion is reduced, and in well-marked cases, the average bone-conduction remaining the same or being increased, the aerial conduction will be reduced until it becomes equal to or much less than bone-conduction. 4. When the bone-conduction is longer than aerial conduction, and yet much less than the average duration of bone-conduction for normal ears, it is an indication not only of middle-ear trouble, but that the nervous apparatus is involved. 5. If the proportion between bone and air remain the same, and the hearing power be much lowered, it is probably an indication of disease of the internal ear. Air-conduction markedly exceeding bone-conduction, the bone-conduction may be entirely lost, and yet air-conduction continue to a limited extent.

**The Action of Quinine upon the Ear.**—Green ("Boston Med. and Surg. Jour," March 8, 1883) has an interesting and timely paper upon the above subject, and formulates his conclusions as follows: 1. Clinical experience the world over is that quinine occasionally produces serious injury to the ears. 2. From our present knowledge, both clinical and experimental, we are justified in asserting that the action of quinine upon the ears is to produce congestion of the labyrinth and tympanum, and sometimes distinct inflammation, with permanent tissue changes. 3. The action of the drug upon the ears should always be considered in prescribing it, and changes in the ears, due to existing or previous inflammation of those organs, constitute a contraindication to the medicine in large doses or for a long time, except under urgent circumstances. 4. Where large and continuous doses are absolutely necessary, an occasional internism of the administration is desirable, if possible, to diminish the risk to the ears.

**Case of Fracture of the Petrous Bone.**—Jacquemart ("Ann. des mal. de l'oreille et du larynx," March, 1883) reports an interesting case of this kind occurring in a physician, from a fall from a wagon upon the left side of his body and face. There was an immediate hemorrhage from the left auditory canal, loss of consciousness for half an hour, and vomiting. He again became unconscious for twenty-four hours. After this he gradually returned to his normal condition. There was never any loss of hearing power. About eighteen months after the accident he became conscious of a bruit and a beating in the left ear, isochronous with the pulse and heart movements. When Jacquemart saw him, three years after the accident, he recognized the following condition of affairs: On the left membrana tympani were two white points, one in front and the other behind the handle of the hammer, resembling cicatricial tissue; these were probably the points at which the membrane was injured at the time of the accident. The hearing power was intact. Speech was somewhat slow, owing to sluggish action of the tongue. On the mastoid there was recognized, under pressure, an arterial pulsation synchronous with the pulse, and with the stethoscope there was recognized a murmur, which ceased to be perceived by the patient after the pressure had been continued for some time. The wound in the tympanic membrane might have been occasioned by the direct effect of the concussion of a column of air, or by a fracture of the petrous bone extending into the cavity of the tympanum and involving the drum-head; it was probably due to the latter. Jacquemart thought that there had been an incomplete fracture of the petrous bone, a fissure of the external portion, near the union of the mastoid process with the body of the bone, involving the mastoid as far as the canal of the facial nerve behind, but extending forward across the entire auditory canal, thus tearing the drum-head. The hemorrhage at the time of the accident came from one or more vessels of the membrana tympani. He thought that the pulsation and the bruit were of purely nervous origin.
Anatomical Researches on the Deviations of the Nasal Septum.—Lowenberg ("Arch. of Oto-laryngology," xii, 1) has been making some investigations into the anatomy of the nose, with a view to the solution of the three following problems: 1. Where is the septal and what is the nature of the obstacles which so frequently arrest the catheter during its passage through the nose? 2. What is their role in this operation and in the therapeutics of the nasal fossa? 3. How can we recognize the existence of these obstacles and avoid them in a rational and scientific manner? Anterior rhinoscopy of many cases has led the author to believe that, in the cases in which the catheter encounters an obstacle in the nasal fossa, this is not in the turbinate bones, but in the septum; and it forms there the protuberances or spurs which he has described in a previous article in the "Union médicale" for July 28, 1881. Lowenberg's researches are based on the dissection of more than one hundred fresh heads, and upon an examination of many skulls in museums. In only about one case in seven was the septum found absolutely straight in all its parts. He found that the pathological deviations must be divided into several groups, which he calls vertical deviations and horizontal deviations, the latter being divided into superior and inferior horizontal deviations. Lowenberg calls the lateral deformity of the lower part of the septum the inferior horizontal deviation. It proceeds from the fact that the bony part on the one hand and the cartilaginous part on the other are not in the same vertical plane, but join under a dihedral angle projecting toward one side. In the majority of cases Lowenberg found that the inferior deviation forms the reverse of the superior deviation—that is to say, that the convexity of the one is turned in the opposite direction to that of the other. In certain persons the arrangement is still more irregular; it is like a kind of torsion or undulation of the septum from top to bottom, by means of which the groove of the vomer and the crest of the maxillaries do not participate in the curve of the lower deviation, but deviate in their front part in the same way as the superior deviation. In the minority of cases the convexities of the two horizontal deviations face the same way. Deviations in the vertical direction are not, like the preceding, horizontal or slightly ascending projections, but folds extending from top to bottom along the septum narium in its front part, consequently pertaining especially to the cartilage of the septum. These folds present a convexity toward one side, and a concavity toward the other. To facilitate catheterization under these circumstances, the point is to get round the obstacle and not to remove it. The author rejects any bloody operation, such as the ablation of the deviated portion of the septum. The obstacle may be avoided by catheterization through the opposite nostril in cases where, protuberances do not exist on both sides of the septum. But the method which the author prefers is catheterization guided by simultaneous anterior rhinoscopy. He lays down the very important principle, which every experienced aurist will recognize and indorse, that, in every case requiring our attention for an affection of the ear, the nasal fossa should always be carefully explored, unless the disease be manifestly confined to the external ear or to the auditory meatus. He has devised a speculum for this special purpose, which consists of a metallic tube, shaped like a truncated cone, at the large end of which a sort of handle or palette is implanted almost perpendicularly to the axis of the cone. A rather wide slit extends the length of the speculum on the side opposite that which holds the palette. The instrument, having thin sides, is much lighter than ordinary specula, and its contact with the catheter would not displace the latter so painful a manner to the patient as the ordinary heavy and cumbersome instruments do. After having introduced this speculum into the entrance of the nasal fossa, the palette being above, it is held there by slightly pressing the latter with the thumb of the left hand, the fingers of which are placed against the back of the nose. The slit is in this way directed downward and horizontally, so as to leave the passage free for the introduction of the catheter. When the catheter has passed the narrowed part, the speculum is taken off by turning the slit upward; it then drops off of itself, the slit making room for the stem of the catheter.

A New Theory as to the Functions of the Semicircular Canals.—McBride ("Journ. of Anat. and Phys.," Jan., 1883) thinks that the explanation hitherto advanced as to the functions of the semicircular canals, though probably correct as far as it goes, is quite inadequate to account for all the facts connected with their physiology. If the canals were concerned in equilibrium alone, then, on general principles, it is fair to assume that they would be placed in a position as safe as is consistent with the proper fulfillment of their function. The function of equilibrium could probably be carried on just as well if they were altogether shut off from the auditory apparatus. McBride, therefore, assumes that they have another part to play in the animal economy. It seems probable that this other function is to produce, through the ampullar nerves, reflex rotation of the head and eyes toward the point from which a sound proceeds, and that, further, the afferent impulse may, in the lower animals co-ordinate and brace the muscles necessary for escaping from a danger of which sound is the first indication. The most probable explanation of the exposed condition of the semicircular canals is that, while sonorous vibrations are conveyed by the cochlear nerve to the true auditory center, an afferent impulse is at the same time sent to various motor centers through the ampullar nerves.

Disease of the Ear occurring during the Course of Parotitis.—Rosen ("Arch. of Oto-laryngology," xii, 1) gives an analysis of ten cases carefully reported, and draws the following conclusions: 1. An acute catarrh of the middle ear may occur during the course of mumps, and be attended by fever and vomiting. 2. This catarrh may extend from the parotid gland through the auditory canal and outer layer of the drum-head, or through the mastoid process. 3. An affection of the labyrinth may occur simultaneously, or by extension from the middle ear. 4. It is probable that there are cases where the disease is transferred to the labyrinth in the same manner that an inflammation sometimes occurs in the testes and the breasts during the course of mumps, but this cannot be considered as proved until more detailed experience is furnished of cases observed a few hours after the impairment of hearing occurs. The cases which Rosen has seen have convinced him that any hope of retaining the hearing power must depend upon the prompt use of local anti-ophthalmic means. If the labyrinth is invaded, it is doubtful if the cases are not incurable, even if seen at the instant the hearing becomes affected.

The Filiform Fungi Aspergillus Flavus, Niger, and Fumigatus; Eucytium Cepaea and Aspergillus Glacius, and their Relation to Otophyssis Aspergillina.—Siebenmann ("Zeitschrift für Ohrenheilkunde," xii, 2 and 3) writes at considerable length of the various forms of mycosis aspergillosis of the human ear, with their history, symptoms, pathology and pathology, prognosis and treatment, but this paper contains very little that has not been said before. His conclusions are that in the human ear aspergillus is very rarely located as a membrane upon the epidermis; and, when it is met with here, it is always of the "fumigatus" variety. Aspergillus nigre and flavus is always situated upon the surface of the free rete or upon the corium, without, however, penetrating into the latter. Hence the mycelia of the deeper thallus layers may be surrounded and overgrown by the cells of the rete Malpighii.
Letters to the Editor.

THE PLEDGE EXACTED AT CLEVELAND.

NEW YORK, July 3, 1883.

To the Editor of the New York Medical Journal:

Sir: In my last I was, perhaps, somewhat severe upon the American Medical Association for its choice of its presiding officer, but I am glad that, in one respect at least, I can heartily commend its action. I refer to the pledge, exacted of all those admitted to a share in its deliberations, that they would defend its code of ethics, without change or amendment. I am convinced that nothing which the Association could have done would have shown so clearly the rock of conservatism upon which it stands, and the dignity of its position. Numbers who, after traveling perhaps hundreds of miles, found the door shut in their faces until they should signify their loyalty to its time-honored policy, will learn therefrom a lesson of respect for the power they attempted to ignore.

Dr. Sjoibbs has shown that, in Brooklyn at least, the irregular "legal practitioners" are about equal in number to the regular. They were only a handful when we "drew the line" thirty or forty years ago. That they should have increased in such startling measure shows but too plainly how lax we have been in our repressive action. More of the spirit shown at Cleveland would have cowed them, and prevented the growth of the heresy which it is even now too late to crush out. Stronger measures are the need of the hour, and, in inaugurating them, the Association has taken a step in the right direction, which all but the fanatics of "progress" will applaud.

Yours sincerely,

Boccio.

Miscellany.

THE TRI-STATE MEDICAL ASSOCIATION.—The ninth annual meeting will be held in Indianapolis, September 18th, 19th, and 20th. The work is already far advanced, and the title of each paper should be sent in at once. The reading of each paper must not exceed twenty-five minutes. It is also the rule that each physician who registers must be a member of a local or State society is good reprint. All such are invited. Notice of papers or essays to be presented may be sent to the chairman of the committee on programme, Dr. J. L. Thompson, Indianapolis, to the secretary, Dr. G. W. Burton, Mitchell, Ind., or to the president, Dr. William Porter, St. Louis.

THE WATER-CRESS AS A DRUG AND AS AN ARTICLE OF FOOD.—At a recent meeting of the Paris Société de thérapeutique (Gaz. hebdom. de méd. et de chir.) a note was read from M. Grellety relative to the dietetic and therapeutic qualities of the water-cress. The author maintained that the cress was not so wholesome as was commonly supposed, but that it was difficult of digestion, and that, containing a sulphur, nitrogenous oil with allyl for its base, together with a bitter extractive, iodine, iron, and phosphorus, it might a priori be accounted an irritant.

These views do not seem to have met with much favor at the meeting, judging from the discussion that followed, in which M. Gueneau de Mussy, M. Constantin Paul, M. Dujardin-Beaumetz, and several other gentlemen took part. The idea was accepted that the stems of the cress were possibly difficult of digestion, and it was conceded that the plant ought always to be washed very thoroughly before being served, although no weight was allowed to the popular notion that the cress was rendered irritating and noxious by the accident of a frog's having sprawled upon it.

Considered as a drug, several gentlemen testified to the beneficial action of the cress in certain chronic diseases, especially obstinate eczema and ulceration. The official syrup was regarded as a bad preparation, due, it was thought, to its being clarified with the aid of heat, the effect of which was to give it a disagreeable sulphuraceous odor. The fresh juice, squeezed out with a little press, was recommended by M. Gueneau de Mussy; it left something of an acid taste in the mouth, but this was readily allayed by a little syrup of bitter orange-peel.

CONTROVERSY OF THE BRAIN AND SPINAL CORD.—Dr. John A. lidell, late surgeon to Bellevue Hospital, New York, in an elaborate practical paper on this subject in the July number of the American Journal of the Medical Sciences, discusses the clinical history, diagnosis, prognosis, and treatment of this large and very important class of injuries. While much is said in our text-books on the subject of cerebral concussion—of its dangers and of its importance—but small if any mention is made of the contusions of the brain which so very often complicate the contusions, and impart to them whatever of gravity, if not much, if not little, that they may chance to possess. And still less mention is made of the contusions of the spinal cord. No wonder, then, that bruises of the brain-structure and of the spinal-cord substance occur much more frequently than is generally supposed, that the relationship which exists between these injuries and contusions is not well understood, and that the bruises of these organs often escape even all suspicion during life. That slight or even moderate contusions of the brain sometimes, perhaps not infrequently, occur without being complicated with contusions of the brain, Dr. Lidell does not doubt. Con traction of the brain is, therefore, he believes, not synonymous with concussion of the brain; but, at the same time, all the evidence now collected tends to prove that the severe instances of cerebral concussion are always complicated with cerebral contusion. Concussion of the brain, however, derives its chief importance from the fact that it is very often associated with contusion of the brain; and, in examining a case of cerebral concussion, the question of most importance for the surgeon to decide is whether or not cerebral contusion is also present.

These are points of doctrine which practically have much interest for patients as well as practitioners, because of the influence they are likely to exert in the direction of procuring a correct diagnosis and, consequently, a wise treatment; for, in the disorders of no other parts of the body is it more true that an accurate diagnosis begets a wise plan of treatment than in those of the brain and spinal cord.

POWDERED MEAT IN THE TREATMENT OF PHTHISIA.—M. Deboeuf (Gaz. hebdom. de méd. et de chir.) employs the following method of rendering his poudre de viande palatable: Two spoonfuls of the powder are stirred with cold water in a bowl until the meat seems to be thoroughly dissolved. Two spoonfuls of syrup and an equal amount of sugar are then added. The mixture, after being heated, is given in quantities of six spoonfuls of the powder daily, remarkable results have been produced in the treatment of consumptives.

ARMY INTELLIGENCE.—Official List of Changes of Officers of the Medical Department, United States Army, from June 30, 1883, to July 7, 1883.—IGERS, A., Major and Surgeon. Relieved from the further operation of paragraph 9, S. O. 53, C. S., Department of Texas, and will return to his station, Fort Clark, Texas. Par. 2, S. O. 69, Department of Texas, June 25, 1883, ——— HAYARD, VALANT, Captain and Assistant Surgeon. Assigned to duty with expedition to complete the survey of the country west of the Rio Pecos, Texas. Par. S. O. 63, Department of Texas, June 22, 1883, ——— RAYMOND, HENRY L, First Lieutenant and Assistant Surgeon. Granted leave of absence from July 14, 1883, to September 1, 1883, with permission to go beyond seas, and resignation accepted, to take effect September 1, 1883. S. O. 150, A. G. O., June 30, 1883.

NAVAL INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy for the week ending July 7, 1883.—Medical Inspector A. C. Rhodes detached from the Naval Academy, Annapolis, Md., and ordered to the United States steamer Tennessee, and as Fleet Surgeon of the North Atlantic Station, vice Medical Inspector T. W. Leach, detached and placed on sick leave.

SOCIETY MEETINGS FOR THE COMING WEEK.—Tuesday, July 17th: American Ophthalmological Society (Catskill, N. Y.); Medical Society of the County of Otsego, N. Y. (Cooperstown—annual); Ogdensburg Medical Association. Wednesday, July 18th: American Ophthalmological Society (Catskill, N. Y.).
Lectures and Addresses.

A CLINICAL LECTURE IN GYNÆCOLOGY.

DELIVERED AT THE NEW YORK POLYCLINIC.

By JAMES B. HUNTER, M.D.,

PROFESSOR OF GYNÆCOLOGY.

Fibroid Tumor of the Uterus; Prolapsus.—Anteflexion of the Uterus.—Subacute Endometritis.—Laceration of the Cervix Uteri with Retroversio.—Carcinoma of the Cervix Uteri.—Laceration of the Cervix Uteri.—Anteflexion accompanied by Sterility.—Abscess of the Vulvo-vaginal Gland.—Laceration of the Cervix Uteri.—Long, Conical Cervix; Sterility.

CASE I. Fibroid Tumor of the Uterus; Prolapsus.—Gentlemen: This woman, who has passed the menopause a few years, presents a prolapsus of the uterus almost in the third degree; the organ lies almost completely outside the vulva. It was replaced last week, and a cup pessary was introduced, but, as some distress followed, the patient removed the pessary herself. You will observe, however, that no erosion has followed its use, and doubtless when a larger one is applied it will support the organ perfectly without causing discomfort. Why should the prolapsus in the case of this patient, whose perineum has not been extensively lacerated, and whose uterus is only of moderate size, exist in so severe a degree? You will remember that last week we spoke of certain other conditions complicating these cases, and tending to aggravate the degree of prolapsus, among which was fibroid tumor of the uterus. The gentleman who inserted the pessary last week failed to detect such a tumor, one of considerable size, which exists in the present case. The patient's health, however, being in other respects in a very fair condition, doubtless we shall be able to introduce a pessary that will support the organ, and give her material relief so long as she continues to wear it, without causing much discomfort. This hope is further sustained by the fact that the patient has passed the menopause, and the tumor from henceforward will decrease rather than increase in size. Such being the case, it answers the question which one of you asks, Should the tumor not be removed by an operation? This is altogether unjustifiable, for the prolapsus, of which the tumor is one of the causes, can be corrected by a pessary, and within a few years the tumor itself will doubtless have contracted very greatly, and may finally disappear almost completely. Being subperitoneal, as I believe it to be, it could probably be removed with comparative safety by laparotomy, but the operation is not necessary. The tumor no doubt has been growing for many years, and only within a short time of the menopause reached considerable dimensions, so as to aid materially in aggravating the prolapsus of the uterus, which probably first started in a laceration of the cervix and of the perineum.

In answer to your inquiry, May it not be of a malignant form? I would say that the growth has too regular and smooth an outline for a malignant growth, the latter usually presenting distinctly irregular and even jagged outlines, easily recognizable and very suggestive of its character to the experienced surgeon. Moreover, the patient's general condition is comparatively good, and not in the least indicative of a constitutional affection.

[It may here be remarked that the examination and the application of the treatment of each one of the patients were by the members of the class, under the immediate direction of the speaker.—Reporter.]

CASE II. Anteflexion of the Uterus.—This is a patient, an unmarried woman, suffering from extreme anteflexion of the uterus, who presented herself at the clinic a week ago, at which time we passed sounds for the purpose of dilating the uterine canal and straightening the organ, beginning with a small instrument and gradually increasing the size. As her home was somewhat distant, we could not carry the dilatation on a single occasion to the extent that we might have done had she been in a hospital. A slight amount of pain was caused at the time of the introduction of the instruments, which, however, soon passed away, and left no evil result. We find to-day, however, that recontraction has taken place, and we are unable to go further with the dilatation than on the former occasion on account of the degree of tenderness that she complains of. This patient's case belongs to that rare class of anteflexion of the uterus unaccompanied by dysmenorrhcea. The pain which usually accompanies the condition just before the monthly period is due to the accumulation of the menstrual fluid in the uterine canal because of its inability to escape through the bent and constricted internal and, possibly, external os. Where the patient escapes such pain it is probably to be accounted for, in some instances, by the fact that when the fluid begins to accumulate it so far raises the uterus and straightens its canal that it escapes before accumulating in large quantity. I once treated a patient in whom the anteflexion was so extreme that the uterus presented the form of a fish-hook; yet the patient did not suffer from dysmenorrhcea. These cases are always troublesome to treat, and complete cure can never be promised. They are usually congenital, as is doubtless true in the present case. The treatment consists in dilatation of the cervical canal with graded dilators, at the same time tending more or less to straighten the uterus, and in retaining the organ in its improved position by means of a pessary.

CASE III. Subacute Endometritis.—The next patient is thirty-two years of age, and was here last week, when we recognized profuse leucorrhcea, due to subacute endome tritis. The patient was very sensitive to the passage of the sound. No other abnormal condition whatever could be discovered. Churchill's tincture of iodine was applied to the uterine canal by means of an applicator wrapped with cotton, of which, I may here remark, you should ever have a number on your table, ready for use, for they cost but little, and one alone may not answer your purpose. It is true, as you suggest, that sometimes it is with difficulty that the iodine, the carbolic solution, the nitrate of silver, or other application which you may desire to use, is applied
throughout the entire uterine canal; that it is more or less neutralized in certain cases by the secretions within the cervix before it reaches the fundus; but this may be more or less effectually guarded against by carefully wiping the canal dry with cotton before the solution is introduced. The uterine sound is not usually of much assistance in making the applications. An instrument has lately been invented by means of which, on turning a screw, the solution contained within a syringe may be projected upon the cotton applicator after it has been introduced through the cervical canal up to the fundus of the uterus. You will observe that the patient makes no resistance to the passage of the instrument until the internal os is reached, when she flinches, showing considerable sensitiveness at that point, which is not infrequently the case in endometritis, and which is an indication that great care should be taken in the management of the case. The application should not be made oftener than twice a week, and, if the patient afterward complains of considerable pain, she should be allowed a longer interval for rest. Having made the application, a wad of cotton with a string attached is introduced and rests against the cervix, and may be removed with perfect ease by the patient. The application should not be made two or three days before nor directly after a menstrual period.

Case IV. Laceration of the Cervix Uteri with Retroversion.—This patient was here at a previous clinic, at which time we discovered a severe laceration of the cervix uteri, with a strong degree of retroversion of the organ; the retroversion, indeed, almost assumes the form of a retroflexion. The patient complained of great tenderness on pressure against Douglas's cul-de-sac, so much so that it was considered unwise to attempt to restore the uterus to its normal position, which it would require a little violence to accomplish. We therefore simply made an application of the tincture of iodine to the raw surface of the cervix, and gave the patient general directions with regard to her health, and as to washing out the vagina. The uterus can not be replaced immediately, which would require considerable violence, but it must be done gradually, and the treatment, before it can be said to be successful, will have proved somewhat tedious. There are some small cysts which have sprung up within the cervix that will require to be removed with the scissors in order to effect their permanent cure; it can not be done with any application, although, where an operation would not be allowed, material relief might be obtained by such means.

Case V. Carcinoma of the Cervix Uteri.—In examining this patient, please to introduce your finger into the vagina with great care, as the diagnosis is at present very easily made, and careless manipulation might cause haemorrhage and give the patient unnecessary pain. This woman presented herself at the clinic about a month ago, when we found laceration of the cervix, and a peculiar hard feeling—a feeling as of a whiplord around the wounded portion, which was very suggestive to the experienced gynæcologist. The diagnosis was made of epithelioma of the cervix, and, although in the minds of some there may have been a doubt regarding the case, we felt so positive in our diagnosis that amputation of the cervix was advised, but at that time there was no vacant room in the hospital, and the operation had to be postponed. You see the appearance which the disease has taken on since that time. It has rapidly advanced, the cervical tissues have begun to break down, and the odor is very disagreeable, peculiar to malignant disease. As in many cases, the disease here has developed at the seat of laceration. The statement has been made by some, and denied by others, that frequent pregnancies favor the development of cancer of the uterus. This case might be considered as corroborative of that statement: the patient has had nineteen pregnancies. The only treatment which could be adopted, besides palliative measures, is amputation of the diseased tissue, and it is questionable whether the disease has not advanced too far to justify such operative interference.

Case VI. Laceration of the Cervix Uteri.—This patient I show you to-day in order that you may see the result of the operation performed recently for laceration of the cervix uteri. You will remember that the uterus was retroverted, and that the cervix presented the usual appearance present in such cases, and the patient was suffering from the usual train of symptoms. The cervix now, you will observe, presents almost a perfectly normal appearance, and the uterus has resumed its normal position and remains there. The patient is making use of injections of hot water daily, and doubtless still greater improvement in her symptoms will be manifest within a few days. In answer to your question, I would state that, aside from certain exceptional cases, it is unnecessary to have a patient coming to your office every day; twice or three times a week is often enough for almost every case where the patient’s condition admits of her visiting you at your office; to have a patient come every day of the week, as is required by at least one physician of this city, an irregular, is simply the trick of an impostor. The uterine canal here, as shown by the sound, is not a perfectly typical one, but pursues a somewhat irregular course, as not infrequently happens, and yet it can not be said to be abnormal.

Case VII. Anteflexion accompanied by Sterility. —This patient is twenty years of age; has been married two years; has never been pregnant, although she says she desires to bear children. She suffers from dysmenorrhoea, and pain is particularly severe two days before the flow. Upon examination, we find marked anteflexion, although not in so extreme a degree as in the case before presented, and we shall hope therefore that this patient may receive some benefit from treatment; that she may be so far benefited as to be able to bear children, although it is never well in these cases to promise the patient a positive cure. She has not menstruated for six weeks, and it is not safe, therefore, to pass a sound, notwithstanding the probabilities are altogether against the existence of the pregnant state. Should the method before mentioned prove ineffectual in straightening the uterus, resort might be had to the operation for straightening the canal by cutting a piece out from the external and the internal os, correcting to some extent the acute flexion of the canal which exists near the internal os at present, and thus admitting of a freer exit of the menstrual fluid.
A CLINICAL LECTURE ON EXOPHTHALMIC GOITRE (giving the further progress of the case described in a former lecture*).

DELIVERED AT THE HOSPITAL OF THE UNIVERSITY OF PENNSYLVANIA.

By WILLIAM PEPPER, M.D., LL.D., PROFESSOR AND PROFESSOR OF CLINICAL MEDICINE.

Gentlemen: It is with great regret that I have to tell you that the patient whom you saw a few weeks ago, suffering with a marked degree of exophthalmic goitre, gradually sank despite all that we could do for him, and died on the 15th of this month (February). I have here the specimens removed at the autopsy, and, as I have not yet examined them, I shall ask your attention to the report of the post-mortem examination.

You will remember that when he was admitted to the hospital he was suffering from an enormous goitre, with violent pulsation and rapid action of the heart (the pulse rate reaching 150 a minute under the least excitement), and there was a marked thrill on palpation. A more careful examination of the heart than had been made at the time he was before you revealed a systolic blowing murmur over the body of the organ. There was no albumin in the urine. The blood was not much altered in its corpuscular elements, but was reduced in its total bulk—that is to say, the quantity of the blood was greatly lessened, but the quality was not much impaired. There had been a great loss of flesh. Three months before admission he had weighed one hundred and seventy-five pounds, on admission his weight was one hundred and thirty-eight pounds, and on February 1st it was one hundred and ten pounds. The disease from which he was suffering had apparently been brought on by over-work, great exposure, and the impairment of nutrition resulting from chronic diarrhoea. This diarrhoea continued in an obstinate form after his admission, and was doubtless one cause of the rapid loss of flesh. Although the crisis of the blood, as determined by counting the corpuscles, did not appear to be much impaired, yet, after he had been in the house for some time, he began to suffer from epistaxis, not severe, but frequently recurring. The diarrhoea, as I have said, proved exceedingly difficult to check. Remedies controlled it for a few days, and then it would return again. The same was true of changes in the diet.

A note made on February 8th says: "The liver is enlarged; the gall-bladder is distended; the edge of the liver is thickened and rounded; the tongue is dry and glazed; the pulse is growing more rapid (152 in the recumbent position); the murmurs are becoming more intense, and the dullness over the heart is increasing." There were also observed some signs of engorgement of the lungs and of pleurisy over the base of the left lung; severe attacks of diarrhoea came on every few days; the matters discharged are described as looking like green grass chewed up and spit out. About the 1st of this month a fullness and hardness appeared in the right iliac fossa. An examination of the blood, made by Dr. W. E. Hughes at this time, showed evidences of deterioration. In a cubic millimetre there were but 2,000,000 red blood globules, while the number of the white globules had increased until there was one white to every fifteen red corpuscles. The pulmonary symptoms gradually became more marked, the diarrhoea continued, the pulse became very rapid, and he began to have evening fever. The eyelids no longer covered the eyeballs, but when he was asleep there was a portion, at least one fourth of an inch in width, exposed. As a result of this, there was some conjunctival inflammation. Typhoid symptoms supervened; the teeth were covered with sordes; the tongue was coated with a thick brown fur; the heart beat so violently that it moved the entire body; the fullness in the right iliac fossa remained the same, and the cardiac dullness slightly increased. No albumin appeared in

* See vol. xxxvii, p. 141.
the urine. Thus the case ran on to a fatal termination, apparently from failure of the heart. The rapidity of the heart's action toward death became phenomenal. As counted over the heart, it was 230, 218, and 195 a minute, while the pulse, as nearly as it could be counted, was 140, 160, and 180 a minute, showing that, although the pulse was extremely rapid, it did not keep pace with the excessive frequency of the cardiac action.

The way in which exophthalmic goitre proves fatal is usually by a continued deterioration of the blood, which becomes more and more watery, leading to hemmorhages and dropsy; by greater and greater impairment of the digestive apparatus; and by increasing prostration of the nervous system; the violent heart action continuing, but its force growing weaker and the organ evidently becoming dilated, flabby, and less and less able to maintain the circulation.

I shall now read the report of Dr. Hughes of the conditions found after death.

**Post-mortem made shortly after death.**—Body much emaciated and generally pale, but upper part of chest, neck, and face somewhat congested. Eyelids covered the eyes. Skin slightly exoriated over the back.

**Head.**—Scalp congested. A large quantity of dark blood exuded on section. The pericystum stripped from the skull with remarkalde ease. There were numerous points in the bone from which dark blood flowed. The bones were normal and of the proper thickness. Dura mater adhered tightly to the skull, but was not thickened. The sinuses, veins, and arteries were filled with dark fluid blood. More than a pint in all escaped. No serum in the arachnoid sac. Brain apparently normal, with the exception of perhaps a little congestion. Brain weighed 1,560 grammes. Veins and sinuses of the spinal cord filled with dark fluid blood. The cord and membranes normal.

**Lungs.**—Six ounces of fluid serum were found in the pleural cavity. On the left side numerous firm white bands of adhesions passed between the lung and the lower part of the chest wall and the diaphragm. There were also adhesions between the lobes. On the right side there were only a few adhesions between the lobes and none to the chest wall. In the visceral pleura on the right side there were numerous small bodies resembling tubercles. These have not yet been examined microscopically. They were most marked between the lobes. There were none in the left pleura. The lungs were slightly congested hypostatically. Their structure was normal, with the exception of a small fibrous nodule at the left apex. The bronchial glands were dark and somewhat enlarged.

**Heart.**—The right side of the heart was dilated and filled with dark fluid blood. A slender chicken fat clot extended into the pulmonary artery. The left side was firm and contracted, and the walls were thickened. The valves of the right side were competent; those of the left side were incompetent, the leaflets being slightly thickened but not rigid. The left auricular appendage was rather larger than normal, touching the chest wall. The heart weighed 420 grammes. Both the pulmonary artery and the aorta were dilated, but the lining membrane was normal.

The **thyroid gland** was larger than normal, and hard.

**Thyroid gland.**—This body was of a pinkish-purple color. It was enlarged, the hypertrophy being most marked in the left lobe. On section, it was firm, and evidently contained an overgrowth of fibrous tissue, and numerous small cysts were scattered throughout its substance. The arteries were apparently not enlarged. The gland weighed 255 grammes.

**Liver.**—Weight, 1,540 grammes. It was thick and firm. Externally, it was of a mottled red and gray color. On section, there were found in the right lobe, especially toward its convexity, irregular masses of a purplish brown color, with white spots and streaks scattered through them. No appearance of aicin. Deeper, there was very little of this purplish tissue, but the liver was almost uniformly of a bright yellow, with dark clots of liver tissue in the center of the acini. In the left lobe there was less of this new purplish tissue, and more white, which was scattered through the whole of the lobe, apparently developed around the venules and surrounded by bright liver tissue. The veins were dilated. There were numerous adhesions between neighboring parts and the gall-bladder, which was filled with bile. Some bile also exuded from the section of the liver.

**Pancreas.**—This was of normal size, but very hard, apparently from a development of fibrous tissue. It was more tightly adherent to the surrounding structures than normal. The arteries stood out prominently, and their walls were thickened.

**Spleen.**—The spleen was tightly adherent to the adjacent structures. There was a depression on its convex surface, which appeared to be the result of inflammation. The Malpighian bodies were increased in size. Otherwise the appearance was normal. The spleen weighed 320 grammes.

**Kidneys.**—These weighed, respectively, 210 and 220 grammes. They were congested. The cortical substance was increased and slightly granular. The arteries stood out prominently. The stellate veins on the surface were injected. The capsule was too adherent. On the surface were scattered numerous small cysts. The lower extremity of the right kidney was tilted forward until it was on a level with the anterior surface of the spinal column.

The **abdominal lymphatic glands** were enlarged and purplish.

The **stomach and intestines** were dark, but otherwise normal.

The **esophagus** was enlarged, the superior ganglia were markedly so, but normal in color and consistence. The semilunar ganglion was somewhat enlarged.

The **supra-renal capsules** were small, but otherwise normal.

There was a marked increase of adipose tissue behind the eyeballs, but no discernable dilatation of the arteries.

The report of the **microscopical examination**, made by Dr. Henry F. Fornd, reads as follows:

**Thyroid gland.**—Sections taken from both lobes and from the interior as well as from the periphery showed that the enlargement was due to a uniform glandular hypertrophy. There was nothing abnormal histologically. The acini were not larger and showed no more cystic change than is observed normally. Colloidal material, which was also found normally, was proportionally not in excess. The connective tissue was, however, somewhat increased in some places, and slight extravasations of blood from the capillaries were noted. The condition of the gland can be described as one of numerical hypertrophy.

**Heart.**—Cardiac muscle, taken from both the right and the left side of the organ, showed some fatty change, the fibers showing striation very indistinctly, and being infested by fat granules. The connective tissue was decidedly in excess.

**Liver.**—This organ showed in many places distinct evidences of red atrophy in a slight degree, the changes being expressed by fatty degeneration of the liver cells in the center of some of the lobules and around the smaller branches of the hepatic veins. At the periphery of the individual acini, a few fatty-infiltrated liver cells were seen in the portal zone. The hepatic veins were strongly congested; the portal vessels were empty but normal. In a few places a cataract condition of the gall-ducts was ob-
served, together with some bile infarctions. The condition of the liver expressed an early stage of red atrophy, although it may be said that the usual blood pigment around the hepatic veins was absent.

Kidneys.—These showed evidences of subacute catarrhal nephritis. The renal disease, although well expressed, was of recent origin, as the interstitial changes were only moderately marked, and the epithelium, which was swollen and large and degenerating, showed very little fatty change. There was in several places slight cystic change in the cortical substance. The blood-vessels, particularly the veins, were congested, and the Malpighian bodies were gorged with blood and prominent.

Spleen.—This organ showed the evidences of leucemia. The Malpighian bodies were enormously enlarged, and the cells of the pulp also showed active proliferation.

How unsatisfactory is this examination in many respects! We find very extensive lesions, but some of them are evidently of recent origin, as, for instance, the engorgement of the lungs, the pleural adhesions, and the changes in the kidney. These must, therefore, be regarded as intercurrent affections. The changes in the spleen are more serious. We should have expected to find it greatly enlarged where there was as marked cardiac failure as was here present; but there are also leucemiac changes in the Malpighian corpuscles, and we note that toward the close of life evidences of leucemia were found in the blood. Changes were found in the heart: The mitral valve was incompetent, and there was some fatty degeneration with dilatation, but not sufficient in degree to cause the troublesome symptoms from which this man suffered. It is clear, therefore, that, as usual, we are to find the essence of this disease in a morbid condition of the vaso-motor ganglia.

A point to which I wish particularly to draw your attention is the long-continued diarrhoea, which could not be arrested by diet, strict rest in bed, or any medication we could employ, either by the mouth or by the rectum. As you have heard from the report of the autopsy, no lesion was found in the stomach or intestines. There appears to have been nothing wrong with the mucous lining of the bowel, which was examined throughout its entire extent. It is not improbable, in view of the apparently normal condition of the mucous membrane, that the excessive secretion from the intestinal walls was dependent upon partial paralysis of the nervous filaments going from the solar plexus to the vessels of the intestine. The control which the sympathetic ganglia exercise over intestinal secretion is very positive. Section of the nerve filaments passing from the solar plexus to the intestine will be followed by choleric discharges. It is certain that in cholera infantum and in Asiatic cholera a morbid condition of the abdominal sympathetic has a great deal to do with the intestinal discharges and with the symptoms of profound nervous prostration which attend these diseases. In the present case, the persistent diarrhoea, without ulceration, appears to me to indicate that there must have been a great change in the action of these ganglia. I connect it with the marked disturbance of the vessels controlled by the upper ganglia of the sympathetic, which gave rise to the symptoms of Graves's disease.

It is many years since I have seen the post-mortem results in a case of exophthalmic goitre before. By far the larger proportion of patients can be greatly benefited and even cured by treatment. It is only when the disease of the heart, or of the kidneys, or of the vaso-motor nerves, is organic and deeply seated, or when the secondary changes in the liver, spleen, and kidneys develop to a marked extent, that an unfavorable termination may be expected.

March 3d.—Gentlemen, I have to-day the report of Dr. William E. Hughes, who made the microscopical examination of the sympathetic ganglia in the case of exophthalmic goitre to which I have called your attention on several occasions. It reads as follows:

The cervical ganglia were to the naked eye enlarged and grayish, but not hard. On microscopical examination, they were found densely infiltrated with small round cells, which pushed the nervous elements apart and pressed upon them. The tubules were compressed, distorted, and in some places destroyed. In some places they were infiltrated with a pseudomembrane of small-round cells, looking as though there might have been a slight inflammation of the tubules. The cells were in places indistinct, shriveled, and compressed, their nuclei not discernible; in other places they were granular, with indistinct nuclei; in other places they were crowded with brown pigment cells and granules; and, finally, some of them had entirely disappeared. The walls of the arterioles were thickened. The lymph spaces were dilated.

In the semilunar ganglia the cells were indistinct, taking staining very poorly, and some of them seemed to have undergone a slight amount of peculiar hyaline change. The nuclei and nucleoli took staining well, and were perfectly distinct. The structure was otherwise normal. There was no infiltration of cells, nor any enlargement of the vessels.

The supra-renal capsules were normal.

These changes are far more marked than have hitherto been noted in exophthalmic goitre. It certainly appears probable that they were not merely due to an atrophy of the ganglionic cells, dependent on parenchymatous inflammation of the ganglia. In addition to serious lesions of the ganglionic cells, there were extensive interstitial changes. It is clear that this was one of those cases of exophthalmic goitre where, the lesions of the ganglia being organic, the symptoms were necessarily intractable. The lesions in the semilunar ganglia are not so advanced as those in the cervical sympathetic. At the same time these lesions connect themselves very definitely with the excessive and intractable secretion from the intestinal mucous membrane, and, I have no doubt, constituted, in large part, the essential cause of the diarrhoea which was so prominent a symptom. The changes in the cervical sympathetic ganglia are wholly adequate to explain the marked symptoms connected with the circulation, the thyroid gland, and the eyeballs, and also the failure of all treatment to control those symptoms.

G newal Average of the American Anesthetic Society gives the following formula:

Divide into twenty pills. From four to six to be given in the course of twenty-four hours.
The dislocation of either extremity of the clavicle, although not so excessively rare as that of the cartilages of the ribs, is, nevertheless, to be reckoned among the more infrequent injuries. In the Middlesex Hospital during sixteen years, ending June 30, 1867, dislocation of the clavicle occurred sixteen times among 521 dislocations of the upper extremity, or 3.07 per cent. of all such dislocations. During the same time, 2,705 cases of fracture of the upper extremity were treated at the same institution, or, in all, 3,226 traumatic lesions affecting the bones of the upper extremity presented themselves for treatment at this hospital in which the dislocation of one or the other articulating surface of the clavicle occurred sixteen times, or 49 per cent. of all these injuries. Of these sixteen cases, thirteen were males and three were females. The time of life in which this accident most frequently occurs is between the years of fifteen and thirty, one fourth of the whole number of cases occurring within this period.

From the fact that the only articulation of the upper extremity to the remainder of the skeleton is by means of the claviculo-sternal joint, this is properly regarded as the first point at which a luxation of any of the bones of the upper limb can take place. The extreme rarity of dislocation of the clavicle in comparison with the fracture of this bone has occasioned much surprise. The radius is the only bone in the upper extremity which is more frequently the seat of fracture than the clavicle, while the acromion is the only known dislocation of this limb which is less frequent than that of the clavicle.

The dislocations of the sternal end of the clavicle have been described as forward, backward, and upward. The dislocation forward is generally produced by some violence which pushes the outer end of the clavicle forcibly backward, such as a blow or fall on the front of the shoulder, or in children by pulling the arm. The head of the bone is easily felt beneath the skin, leaving no doubt as to the nature of the injury. According to Richet and Després, forward displacements of the internal extremity of the clavicle are very seldom observed, on account of the character of the articulation with the scapula, and the powerful muscular attachments which support the outer extremity of the bone. According to all those who have observed this accident, it has uniformly resulted from violence which had for its effect a powerful backward movement of the shoulder, thus producing rupture of the ligaments of the sterno-clavicular articulation. Boyer saw one case in which the luxation was produced by a dancing-master who forcibly thrust the shoulders of a pupil backward in order to correct a faulty position. Desault observed a case in a porter who met with this accident while carrying a heavy basket by means of a strap over the shoulder. The weight of the basket pulled the shoulder backward with sufficient force to cause a dislocation of the sternal end of the clavicle. Moliére reported a case in which a dislocation of the sternal extremity of the clavicle was produced in a child who was caught by one arm while falling from a coach. Professor F. H. Hamilton has recorded the case of a man, aged forty-five years, who was thrown from a horse and suffered a fracture of one leg, and a forward dislocation of the left clavicle at the sternal end. The case occurred in the practice of Professor White, of Buffalo. No mechanical treatment was of any benefit, and at the end of two years the position of the head of the bone was unchanged. Movement of the shoulder forward or backward was accompanied by a corresponding movement of the sternal end of the clavicle. The injured arm was not quite so strong as the other, and its freedom of motion was somewhat impaired.

Professor Hamilton also mentions the case of a lad, twelve years old, who fell into a cellar, August 20, 1855, and adds: “On the fifth day I found the bone displaced.” The result is not mentioned, and there is no further description to identify the case or locate the injury. Another case mentioned by the same author occurred in a boy who was treated at the Buffalo Hospital, and was seen by Professor Hamilton, who said: “Five days after, I found the bone out and quite movable.” Treatment did not reduce the deformity, though function of the limb is said to have been restored. In all the other known cases of this dislocation, the accident has been caused by falling upon the shoulder, and in all cases the injury has resulted from an exaggeration of a physiological movement. It is certainly surprising that a gentleman like Professor Hamilton should have neglected to make a careful statement of cases of this rare injury which have come under his personal observation. In two of the cases which he reports in his work as having himself seen, he does not state the location of the head of the bone, nor even the side of the body upon which the injury was sustained. The omission of such essential particulars has caused the greatest confusion in the collection of similar cases, and materially lessens or quite destroys their value for statistical reference.

Concerning the backward dislocation of the clavicle, Richet and Després speak thus: “The backward dislocation has been observed a certain number of times, and is the least rare of the dislocations of the clavicle except that beneath the acromion. It is most frequently produced by some force which has the effect of carrying the shoulder forcibly forward (Sir Astley Cooper). It has been known to occur from a fall, driving the clavicle toward the middle line of the body by pressure upon the shoulder, or by exercising direct backward pressure upon the internal end of the clavicle (Spanda, Pellieux). A case is reported in which the sternal end of the clavicle was dislocated

* “Fractures and Dislocations,” 1871, p. 562.
backward by the kick of a horse, the blow being received upon the front of the chest in the clavicular region. Richet and Desprès state that "in this lesion the ligaments of articulation and the tendon of the sterno-clido-mastoid are torn from their attachments to the sternum, and the internal end of the clavicle is found behind the supra-sternal notch, and usually more or less above or below; but it is only very rarely that the end of the bone disappears behind the body of the sternum." One case is reported by Sir Astley Cooper of gradual displacement of the clavicle backward in a patient with rabies, in which pressure upon the oesophagus ensued requiring resection of the end of the bone, which was performed by Mr. Davie. A case is reported by Mr. Holmes, from the practice of Mr. Dr Morgan in 1892, in which a girl ten years old was knocked down by a carriage and was thought to have been trodden upon by one of the horses. There was dyspnea, and where the head of the right clavicle should be was a depression into which the finger might be thrust, and the articular surface of the sternum could be plainly felt, while the head of the clavicle was evidently behind it. The treatment was by a splint behind the shoulders, with a pad between it and the spine, by which the shoulders were drawn backward. The dislocation was immediately reduced, the treatment was continued for four weeks, when the articulation was quite firm and the arm could be moved without causing pain.

The dislocation upward appears to be the least frequent of all, and has only recently been recognized as a distinct surgical lesion. Five cases of this injury are recorded in Europe, and Professor Hamilton has added one in America. The recorded causation is interesting, and corresponds almost exactly with that in our patient. Mr. Flower says: "They seem all to have been occasioned by a violent force which carried the shoulder downward and inward." The head of the bone is felt above the upper border of the sternum, in one recorded case lying between the sterno-mastoid and sterno-hyoid muscles. Reduction is easily effected, but it is well-nigh impossible to retain the head of the bone in position, and I am not able to find the record of a case in which this was accomplished. There is generally considerable permanent displacement of the end of the bone, and always more or less impairment of certain functions of the corresponding arm. In one recorded case the patient was unable to lift weights above the head with the arm of the injured side, and our patient is prevented from executing some of the common movements of the arm on that side.

Dr. Hamilton states that "this injury seems to have been produced in all cases, so far as can be ascertained, by a force operating upon the end and top of the shoulder, in consequence of which the head of the clavicle is pushed and at the same time lifted, as it were, from its socket, tearing not only its capsule, with the ligaments which immediately invest the capsule, but also, in some instances, the costo-clavicular ligament, with some fibers of the subclavian muscle. The sternal end of the clavicle is found riding on the top of the sternum, its head being placed between the sternal fasciculus of the sterno-clido-mastoid muscle on the one hand and the sterno-hyoid on the other."

To quote again from Richet and Desprès: "The dislocation upward is very rare. Thus far but two cases are known. The dislocation is produced, so far as known, only by violence acting forcibly downward upon the extremity of the shoulder. The only two reported cases were observed by Sédillot and Baraduc, in one of which the end of the clavicle was easily felt above the supra-sternal notch, and a triangular depression existed beneath it at the seat of the sterno-clavicular articulation, while in Baraduc's case the extremity of the bone seemed to be situated between the bodies of the sterno-mastoid and the sterno-hyoid muscles. In certainly one of these cases there was permanent displacement of the internal end of the clavicle, and the patient never fully recovered the motions of the injured arm." Dr. Carl Eimmert, in his great work, "Lehrbuch der Chirurgie," agrees entirely with what has already been presented from other authors concerning dislocations of the sternal end of the clavicle, and adds the notes of an American case which I have not found elsewhere mentioned in continental literature, but which is probably that reported by Professor Hamilton,* as follows: "J. M., aged forty-four, August 28, 1858, while seated upon a load of wood, was caught under the bar of a gateway and violently crushed, the right shoulder being forced downward and a little backward.... The sternal extremity of the right clavicle was thrown upward so far as to rest upon the front of the thyroid cartilage, occasioning considerable pain, difficulty of respiration, and loss of speech." Permanent deformity, consisting of an upward projection of the head of the clavicle to the extent of half an inch, and an inward displacement of the head of the bone toward the median line, together with protrusion forward, remained. There was inability in the arm when executing movements above the head.†

Professor Hamilton also mentions another case of this accident in a woman of fifty, whom he saw nine weeks after a fall, but he has given no description of the injury, not even designating the side of the body upon which the

---

† Since finishing this paper, the notes of the following additional case have kindly been placed at my service by Dr. Marcy, the attending surgeon:

**BOSTON, MAY 18, 1883.**

**DEAR DR. BLODGETT:**

In March, 1872, I saw, soon after the accident, Mrs. Charles Wood, then living on Lincoln Street, Cambridgeport, who had fallen down a flight of stairs and struck the left shoulder against the wall. The chief injury was the dislocation of the sternal end of the clavicle inward and upward. It seemed almost entirely free from its attachment to the sternum. The sterno-clido-mastoid, in certain movements of the head, lifted the clavicle, and, of course, such movements were attended with pain. The attempt was made to keep the shoulder up, out, and back, which movement readily reduced the dislocation, but the result was not satisfactory. When last seen, quite a period after the injury—months—the sternal end remained about half an inch nearer the median line than its fellow, and higher by about the thickness of the bone. The mobility of the arm was very nearly perfect, and not seriously impaired in its usefulness, although the end of the sternum moved quite a little with certain movements of the shoulder. I should have reported the case, but came in just as you completed your paper, and thought it, therefore, wise to remain silent.

Very truly,

H. O. Marcy.
dislocation existed, so that this case is not available for statistical purposes.

Bryant, in his work on surgery, mentions the case of a woman, aged twenty, whom he saw two years after the injury, in which both clavicles had been dislocated, and were found resting upon the top of the sternum. They could be easily returned to their proper position, but, on removing the pressure, the displacement immediately returned. He also records a case of backward dislocation in a man aged fifty-two, who was injured by falling bricks. In neither of these cases is contained any accurate description of the injuries or the treatment, and they must be regarded with a certain amount of distrust, from the absence of most essential particulars. Mr. Hutchinson reports the case of a young man who was caught between a locomotive and a platform, and was "rolled round and round like a ninepin," by which a dislocation of both extremities of one clavicle was produced. There is no record of treatment or of the result, which would certainly have been possible with proper care on the part of the surgeon; and this important omission, especially when the extraordinary character of the injury is considered. throws grave doubts upon the authenticity of the case. Dr. Col, in the "Gazette des hôpitaux," reports the same injury in a girl aged seventeen, who was caught between the shaft of a wagon and a wall. The left clavicle was dislocated at both ends, the entire bone being displaced forward, and projecting at both ends. The treatment lasted two months, and resulted in a restoration of function, so that the girl resumed her former occupation.

Dr. J. F. South gives an account of a case of compound dislocation of the clavicle backward, which he says he saw in St. Thomas’s Hospital in September, 1833. The patient was a man who had been buried by a slip of earth while excavating for a railway, and was injured by the sharp end of a pickaxe which had been driven into his chest. There was emphysema of the right side of the chest, and the right clavicle was separated from its sternal attachment and dislocated backward, so that it lay upon the right anterior aspect of the windpipe, and somewhat interfered with respiration and deglutition. The dislocation was reduced by drawing the shoulders backward and confining them in that position, the elbow being brought forward and fastened to the side. The wound was covered with sticking-plaster. The patient left his bed at the end of three weeks, and in six weeks was discharged. The sternal end of the clavicle was still a little backward, and more movable than natural.

An analysis of the reported cases of dislocation of the costal cartilages shows a lamentable want of care in the description of the injury, in some cases neither the age nor sex of the patient, nor location of the injury, being mentioned, and no indication being afforded by which the same case might be recognized if included in the tables of other observers. The same patients are to some extent quoted by different writers, the number of cases thus appearing larger than is actually the fact.

By comparing the descriptions of the cases enumerated in this paper, we must conclude that the five reported by Mr. Poland are also contained in the list of M. Chaussier, who is much more explicit in the details of each case. Mr. Poland’s first case, in which the injury was caused by dumb-bells, is evidently the same case which Chaussier reports as a dislocation of a cartilage in a young man produced by violently throwing the arm backward.

The second case, resulting from a drunken fall, is certainly the same individual whom M. Chaussier mentions as sustaining a dislocation of one of the cartilages while drunk. The third of Mr. Poland’s cases, affecting a baker, may be either the third or fourth of M. Chaussier’s list of dislocation of the ribs upon the cartilages, and, finally, the case which Mr. Poland describes as a dislocation of the fourth, the third, and sixth ribs upon the cartilages is probably the same which M. Chaussier describes as a dislocation of most of the ribs upon the cartilages. The remaining undescribed case is also probably included in M. Chaussier’s list. Mr. Poland’s entire list of five cases, therefore, probably corresponds to identical cases reported by M. Chaussier. The case reported by Professor Gross is lacking in details, and the symptoms he enumerates are not those which we should expect from dislocation of the cartilages, but belong to fractures of osseous tissues. This interesting case, therefore, is not included in the analysis of cases, as will be evident from a glance at the following table presenting the cases collected by each of these distinguished writers.

Note.—The latest important surgical work, the colossal "Hand- |
buch" of Eulenberg, which is at present in the press, contains the |
statement that the forward dislocation of the clavicle has been ob- |
served nineteen times, the backward dislocation sixteen times, and |
the upward dislocation nine times; and that simultaneous dislocation |
of both ends of the clavicle has been observed three times. No cases or |
data are given, and no classification of causation, or the sex of the |
individuals, is mentioned.

Malgaige, in his work on dislocations, collected twenty seven cases of |
forward dislocation of the clavicle, of which fourteen were in men and |
six in women. The cases are not identified, nor the lesions described. |
He also presents eleven cases of backward dislocation of the clavicle, |
of whom ten were in men and one was in a woman. He states that upward |
dislocation of the clavicle has occurred in five cases, of whom four were in men and one was in a woman.

For the reasons alluded to on a previous page, as well as the ab- |
scence of accurate description and identification of individual cases, the |
foregoing statements of the number of observed instances of these |
recent injuries is thought to be liable to error, and these figures are not |
included in any of the results here presented. It is certainly not |
demanding too much if we require a description of such excessively rare |
and curious injuries as shall enable the reader to determine posi- |
tively whether the same cases are included in the tables of different |
authorities. The absence of any means of knowing this in the state- |
ments contained in Eulenberg’s work, and in that of Malgaige, leads
COE: SARCOMA OF THE UTERUS.

65

can not avoid the inference that it is less rare than is generally supposed. But, while it is doubtless true, as the latter writer suggests, that many sarcomatous growths are overlooked, being regarded as fibrous or cancerous in their nature, it is equally certain that the diagnosis of diffuse sarcoma of the uterine mucous membrane is often hastily made in cases of simple endometritis fungosa.* It is not the purpose of this article to generalize upon this form of malignant disease, which has been so thoroughly discussed by Gussarov† (to whose work the reader should refer for the literature of the subject), but to mention briefly the following cases, which seemed to be illustrative. The patients were all in the Woman's Hospital since the beginning of the present year, and remained under observation during periods varying from a fortnight to two months. The three who survived were all heard from a few days since, so that there is no doubt as to their present condition.

Case I.—Mrs. B., aged forty-one, married twenty-five years had three children and three miscarriages. She was admitted to the hospital December 18, 1882, with a history of profuse menstruation since her last miscarriage, ten years previously. During the six months before entrance she had been able to walk with difficulty, owing to the presence of shooting pains in the back and groins. The pain in the back was sometimes unbearable and extended down both limbs. Menorrhagia excessive. There was no mention of an offensive discharge from the vagina during the inter-menstrual period. Patient's general condition poor. Examination showed that the uterus was enlarged and antverted, with a depth of three and a half inches. The os was not dilated, so that it was necessary to employ laminea uteri tents before the dull-wire curette could be introduced. A quantity of soft, cauliflower-like material was scraped away, which was, unfortunately, not examined microscopically, the inference being that the case was one of ordinary fungosities.‡ Subsequent to the operation the vaginal discharge became so offensive that intrauterine injections were used. A month later the os remained patulous, the foul discharge persisted, and the pelvic pains were rather increased in severity. The curette, passed within the uterine cavity, encountered a soft, spongy mucous membrane. Small bits of tissue were detached from time to time and examined under the microscope, but with a negative result; the sections could not be distinguished from those which the writer had so often made in specimens of hyperplastic endometritis. But here was a case in which the clinical history came to the aid of the microscope. The patient's health rapidly depreciated, her bad symptoms continued, and the diagnosis of malignant disease was inevitable. She was discharged two months after entering the hospital, and is still declining steadily, without hope of recovery.

Case II.—Mrs. J., aged fifty, entered the hospital September 15, 1883, for the removal of a large ovarian cyst. The case was reported at length in a former number of this journal,* and will not be repeated here. Suffice it to say that, after several accidents, she recovered from ovariotomy, to have a uterine polypus removed two months later. The tumor was easily detached, as the pedicle had already begun to slough; but this simple operation was followed by a profuse, watery, foul-smelling discharge, accompanied by darting pains in the groins and lower part of the abdomen. The woman's convalescence was retarded, and her health failed rapidly. A surprising
local change occurred, within a week after the removal of the innocent growth (an unmistakable fibroid), the posterior lip of the cervix had almost entirely disappeared by a necrotic process, which took its origin at the site of the former pedicle, the fornix vaginae was firm and resisting to the touch, and the entire cervix was fixed—in short, there was every evidence of the invasion of malignant disease. The finger introduced within the patulous os impinged against a soft, fungoid mass, which was evidently breaking down.

As stated in the writer's previous report, the characteristic appearances of sarcoma were not noted in the sloughy masses scraped from the uterine cavity on several occasions, so that he expressed considerable doubt as to the correctness of the diagnosis of sarcoma.* The patient was discharged January 14th, and since then has been under constant observation. Her general health has improved since leaving the hospital, so that she has actually gained in weight; there has been no hemorrhage or foul discharge; the pain is still present, though less severe. Locally, there has been but little change during the last four months. The uterus is still enlarged, and contains a mass of spongy material, the cervix is immovable, but there is no evidence of any extension of the disease; still, all doubt as to its character has been removed, because the writer has obtained bits of tissue with the curette which show on section typical small-round-celled sarcoma. The operation of extirpation of the uterus has been advised, and seems to offer a fair prospect of success.

Case III.—Miss S., aged thirty-eight, admitted March 3, 1883. Menstruation always irregular, with profuse flow. One year ago she began to have severe dragging pains in the pelvis, attended with frequent attacks of metrorrhagia, which had persisted up to the time of entrance. There was a constant watery discharge from the vagina of foul odor. She was much emaciated, with a well-marked cachexia.

Examination showed a uterus enlarged and tender on palpation. Through the gaping as a dull-wire curette was easily introduced and a large mass of soft brain-like material removed, the operation not being attended with either pain or hemorrhage. A careful examination of the growth proved it to be sarcoma of the large-round-celled variety. The patient had an increase of pain after the curetting, and the discharge increased in amount and offensiveness, while her general condition became very bad. She improved under treatment so as to be discharged a month after entrance, somewhat better than when she came in. When seen a week ago, she was so much stronger that she had returned to her work.

Case IV.—Mrs. S., aged forty, entered the hospital May 5, 1883. She had been married seventeen years, and had one child. Her menstrual history had been normal until six months previously, when she began to flow profusely at her periods, which recurred every two or three weeks. During the intervals there had been a constant sanguineous discharge, not especially offensive, and severe pains in the left groin and hypogastrum. When admitted she was blanched, very weak, and had no appetite. Required opiates to relieve pain, and was tamponed repeatedly because of recurring hemorrhages. Vaginal examination disclosed a uterus enlarged to the size of the gravid organ between the third and fourth months, sensitive on pressure above the symphysis. With a widely dilated os, which was filled with a smooth, round tumor, apparently a fibroid. The cervix was incised bilaterally and the tumor removed piecemeal with the spoon-saw, as it was too friable to come away en masse. The fragments (weighing nearly a pound) were of softer consistence than those of a fibrous growth, and the tumor was apparently without a capsule. Hardened sections presented all the appearances of spinule-celled sarcoma—a condition which had been suspected early in the operation. There was no hemorrhage of any consequence. On the morning of the second day after operation the temperature rose to 105° F. (the rise not being preceded by a premonitory chill), while the pulse ranged from 140 to 150, the patient at the same time complaining of severe pain over the fundus uteri. As there was a foul-smelling discharge from the uterus, the cavity was syringed out with warm carbolic water at intervals of three hours, and this was continued during the next six days. Seventy-five grains of quinine and the continuous use of the abdominal ice-coil (which has replaced the cold douche as an antipyretic at the hospital) failed to control the temperature, which did not fall below 104° until the following night. In spite of every endeavor, the patient gradually sank as the symptoms of septic absorption became more marked, and succumbed on the eighth day succeeding the operation. Though an autopsy could not be obtained, there remained no doubt as to the character of the uterine tumor, and the ultimate cause of death.

It is not possible, from such a small number of cases, to make any general deductions which could be of value. The writer can only add that he has been able to verify the statements of Dr. Thomas in his clear and concise paper before alluded to, and has been impressed with the necessity of collecting all of the evidence—both anatomical and clinical—before deciding upon the existence of sarcomatous disease of the uterus. But there will be cases in which a positive diagnosis is impossible, except after months of observation. The subject of fungous endometritis is too wide for discussion here, and Guissow has summed up the main clinical points of difference between this condition and that of the malignant growth which it so closely simulates. Yet even he acknowledges his inability to draw a sharp line of distinction anatomically.

"The microscopic examination," he says, "of single isolated masses does not lead to a very definite conclusion; we often meet with bits of sarcomatous tissue which are made up of perfectly healthy mucous membrane, and, on the contrary, in cases of simple hypertrophy, with pieces which resemble small-celled sarcoma."

Book Notices.

As stated in the preface, the aim of this little book is to enable the beginner to gain a thorough knowledge of the anatomy of the bird, the domestic pigeon being selected as a typical subject. One hundred and twenty pages are devoted to osteology, because of the characteristic nature of the bird's skeleton, the dissection of the muscles, nerves, and special organs occupying the remaining fifty pages. The student of biology will find the
arrangement of the volume similar to that of the hand-books so ably edited by Huxley. We can not too highly commend the modern method of teaching comparative anatomy, wherein the beginner is taught to master the details of a single subject, instead of endeavoring to gain a wider, but superficial knowledge of several. It is only by such work as this that true science can be advanced.

This will undoubtedly be a useful work of reference to the manufacturing chemist, though we can hardly conceive that it “supplies a want” of the medical public.

The book can not lay claim to much originality, is uneven in character, and fairly bristles with ponderous and useless chemical formulae. While we agree with the authors, in the preface to their first edition, as to the “increasing obligations of the pharmacist and the physician,” and the need of higher scientific attainments, this volume does not commend itself to us as a practical aid to the latter. The present edition has been enlarged and revised, special attention being given to the sections on toxicology. There are nearly two hundred illustrations, principally of well-known chemical apparatus.

We question the need of another hand-book upon this subject, since the literature quoted in the introduction to this monograph is already so extensive.

Following a few practical hints on the different solutions for hypodermic injection, varieties of syringes, etc., is a list of drugs, arranged conveniently in alphabetical order. Of these we conceive that the reader will employ very few. A section upon phenic acid will be read with interest, also a short paragraph on the hypodermic injection of water. The most extended chapters are those on mercury, morphine, quinine, and strychnine.

The book is compact in its general arrangement, the information it contains being presented in the most condensed form.

The subject of this work is one which has received little special notice, if we except chloral, opium, and hashish. Dr. Lewin mentions every important drug in the pharmacopoeia, and devotes special attention to quinine, salicylic acid, pilocarpine, and other drugs which have been much discussed of late. The book is full of valuable information, and should be in the library of every practicing physician.

This work is intended as a practical guide for students, and the effort is made everywhere to put everything in the simplest form. The important points in each article are abundantly emphasized, and diagrams and illustrations are frequently resorted to by way of explanation. To a student who has not time to read much, such a work as this would be very convenient as a manual. The style is good, and in not a few instances the author has succeeded in making descriptions much more intelligible and striking than those of the same subjects in other books.

Electricity in Medicine and Surgery. By GEORGE C. FITZ, M. D., Professor of the Theory and Practice of Medicine in the American Medical College of St. Louis, St. Louis, 1883. Pp. 83. [Price, $1.]

This work is very short and simple, and seems to be intended for those who have never studied electricity, and who wish merely to learn enough about it to employ them to some extent in practice. The larger part of the work is taken up in describing different forms of electrical apparatus, and how to use them. A short summary is appended of diseases which are likely to be benefited by the use of electricity. A few cases are also detailed as illustrating results which may be expected to follow treatment with electricity.

DySPLASIA FROM THE USE OF SALICYLIC ACID—Dr. Louvain, of Liège, has met with several cases in which difficulty of breathing was due to the administration of moderate doses of salicylic acid; the breathing was labored and rapid.—Boston Med. and Surg. Jour.
THE NEW YORK MEDICAL JOURNAL,
A Weekly Review of Medicine.

NEW YORK, SATURDAY, JULY 21, 1883.

THE "DOC."

Anthropologists have sadly neglected one of the most interesting types of the medical man, namely, the "doc." So marked are his characteristics, nevertheless, that he may be said to constitute a species, and one of great importance to a correct shaping of our notions of development. Ontogenists and phylogenists may contend as they like over the origin of species in general, but in the case of the "doc," a positive statement may be made showing what is at once the key to his character and the determining cause of his differentiation as a species. That statement is this: Most medical men have on one occasion or another been addressed as "doc." Such a salutation always comes from the vulgar. The ordinary man is annoyed, and feels half-inclined to show resentment, when so addressed; but, reflecting that no insult is intended, but that the term is rather meant as one expressive of a degree of familiarity to which the speaker aspires to be admitted, and one by which he is feeling his way, as it were, the individual to whom the title is applied tempers his anger to toleration, but frowns unmistakably upon his interlocutor's advances. Not so the "doc."; he positively relishes the appellation, and by showing his gusto not only evinces that he has been fittingly addressed, but proclaims himself possessed of the characteristics that make it impossible for him to be anything but a "doc."

The "doc." bears the same relation to the doctor that the "gent." bears to the gentleman. Neither of these diminutives is ever applied with the faintest approach to propriety to an individual at all above shabby gentility, and as a general thing they stand for characteristics much lower in the scale, attaching to persons hovering on the outskirts of respectability. We might, indeed, adopt "gent." as a generic term, the genius to include the medical species.

Shut out as the "doc." is from refined society, he betakes himself to haunts and devices peculiarly his own. Ostensibly living by the practice of medicine, and really trying in his feeble but offensive way to make that pursuit bring in something to aid in sustaining his valuable life, his necessities are actually met by shifts for which he is better fitted, and for which he seems to have a decided bent. But, little as medicine counts for among the "doc.'s" resources, it is with the manner in which he handles it that we are interested, rather than with what else pertains to his course of life.

"Docs." are of high and of low degree. Some specimens succeed in keeping up appearances fairly, while occasionally one is met with so put to it as to have his office "under his hat." The "doc." is proud of belonging to the profession, and never loses an opportunity of letting his light shine before men, penny-dip that it is. He usually has a diploma, and he is careful to hang it conspicuously in his office. Let a chance remark be made in his hearing concerning some case of sickness, and he will at once, and without waiting for the formality of an introduction, proceed to deliver himself of any number of wise comments, all going to give the impression that it would be well to secure his connection with the case. If he happens to meet a stranger afflicted with some visible infirmity, he makes the matter the subject of conversation, apparently unconscious that he is taking a liberty. A wen or a fatty tumor is to him a veritable bonne bouche; he has no hesitation in handling it, and makes no pretense of concealing his eagerness to relieve the afflicted individual. These overtures, it is true, rarely end in anything to his advantage, but there are occasions on which he fairly hits the bull's-eye; any street accident, for instance, gives him an opportunity to play the oracle before the motley group that soon gathers, to hand his card to the newspaper reporters, and possibly to collect at least one fee.

The "doc." is obstreperous and loud-spoken, and apt to be both profane and obscene. Hence it is in the highest degree annoying to a doctor to be accosted by him in any public place, for the "doc." is sure to broach medical matters, and that, too, with a mixture of coarseness and levity peculiarly trying to the person addressed, who can not shake off a certain nervous dread lest the strangers present, who have heard him called by name, and have pricked up their ears out of morbid curiosity concerning the topic touched upon, should, in spite of all the dignity and reserve he can call to his aid, judge him by the company he keeps. A street-car is a favorite place for the "doc." thus to torture his victim. There is no possibility of escape, short of breaking the continuity of one's journey, involving, perhaps, failure to keep an appointment.

There are other unlovely features about the "doc." but in the main he is a harmless being. His existence is none the less an opprobrium, however, and it is to be hoped that the day is not far distant when a State examination, or some equivalent obstacle to the indiscriminate equipment of human beings with the degree of doctor in medicine, shall gradually put an end to the species.

THE MEETING OF THE BRITISH MEDICAL ASSOCIATION.

At the annual meeting of the British Medical Association, to be held in Liverpool on the 31st of this month and the 1st, 2d, and 3d of August, worthy addresses will doubtless be given in the various leading branches of medicine, but, judging from the list of papers that have been promised, we fear that as a whole the meeting will scarcely be as interesting as usual. Perhaps the unattractiveness of Liverpool counts for something in the matter.

There is no doubt, however, that some of the papers will be well worth listening to. In that category we should place a paper on Spastic Paralysis, by Dr. A. Hughes Bennett; a note on the Mechanism of the Cheyne-Stokes Respiration, by Dr. Byron Bramwell; a paper on Headache, by Dr. T. Lauder Brunton; one on Early Tapping in Cases of Ascites, by Dr.
LEADING ARTICLES.

Austin Flint, of New York; one by Dr. William Strange, on Sporadic Septicemia; one on Roux's Amputation at the Ankle, by Mr. T. H. Bartlesee; one on Amputation by Oblique Circular Incision, by Mr. James Hardie; one on Plaster-of-Paris Bandages in the Treatment of Recent Fractures, by Mr. Christopher Heath; one on Osteotomy, by Dr. Rabaghiati; one on Shortening of the Round Ligaments for the Cure of Some Forms of Uterine Displacement, by Dr. William Alexander; one entitled Are Diseases of the Ovary (especially Cystoma) on the Increase? by Mr. Lawson Tait; one on Diseases and Injuries to Health attributed to Vaccination, by Mr. M. D. Makuna; one on Hospital Construction, by Captain Galtón; a note on Congenital Aortic Bands, by Dr. R. S. Archer; a paper on the Chemical Constituents of the Brain, by Dr. J. L. W. Thudichum; one on Ulcers of the Cornea, by Mr. G. A. Crichtett; one on the Transference of Conjunctiva from the Rabbit to the Human Subject for the Cure of Symblepharon, by Dr. John R. Wolfe; one on the Alliance of Rheumatism and Chorea, by Dr. O. Sturges; and one on the Prognosis of Chronic Non-suppurative Inflammation of the Middle Ear, by Dr. P. McBride.

Moreover, several important discussions are announced, including one on Aphasia, to be opened by Professor Gairdner, of Glasgow; one on the Causes and Consequences of Abnormal Tension in the Arteries, to be opened by Dr. Broadbent; one on the Nature of Purpura, to be opened by Dr. Stephen Mackenzie; one on the Surgery of the Kidney, to be opened by Mr. Clement Lucas; one on the Treatment of Intestinal Obstruction; one on Total and Partial Removal of the Uterus for Malignant Disease, to be introduced by papers by Professor Schroeder, of Berlin, and Dr. Wallace; one on the Operative Treatment of Fibrous Tumors of the Uterus, to be introduced by papers by Dr. Keith, Mr. Knowles Thornton, and Mr. Lawson Tait; one on "Metria," to be introduced by a paper by Dr. Atthill; one on Micro-organisms in Disease, to be opened by Dr. Dreschfeld; one on Cerebral Localization in Relation to Psychological Medicine, to be opened by Mr. Bevan Lewis; and one on the Etiology and Pathology of Summer Diarrhoea, to be opened by Dr. Ballard.

If, with such an array of papers and discussions that are likely to prove noteworthy—and the list here given does not by any means include all that promise to be profitable—we have ventured to question whether the meeting will come quite up to the standard, that very doubt shows our recognition of the superlative excellence of the association's annual meetings as a general thing. The least interesting of them, indeed, looking back upon them for many years past, have been of a character to do credit to the profession in any country.

THE MORAL ASPECT OF ENFORCED STERILITY.

Elsewhere in this issue the reader will find a letter from Dr. Q. Cincinnatus Smith, of Austin, Texas, which seems to call for some notice, inasmuch as the writer charges this journal with inconsistency. Referring to the number for June 30th, he says: "On page 715 . . . we are told what a terribly wicked thing it is to prevent conception, etc.; then, again, on page 728, we are told that a certain 'unfortunate woman became pregnant again, although warned of the danger,' etc.

In the editorial article from which Dr. Smith makes his first quotation the view was put forward that the prevention of conception was morally on a par with the production of abortion; the article containing the passage next quoted by him was taken from the "British Medical Journal," and credited to that journal. In the editorial article in question it was not thought necessary to state in so many words that it was to the prevention of conception for other than medical reasons that reference was intended, for certainly no careful reader could fail to see that such was the case; in the "British Medical Journal" article, on the other hand, the author evidently "warned" his patient in order that she might escape the grave infection of albuminuric retinitis. The two cases are in no wise parallel; there is a vast difference between the conduct of a medical man who convives at a cold-blooded series of outrages on nature, simply to suit the wishes or the fancied necessities of those who would dance without paying the fiddler, and the course to which a physician's own conscience impels him, in order to save his patient from serious bodily harm, although the act may be the same in both instances. The contrast is as great as between the careful performance of paracentesis pericardii for sufficient cause and the indiscriminate stabbing of men in the heart. Such being the case, it is not easy to see how any inconsistency has been shown on the part of this journal; but of that our readers are abundantly able to judge.

Our correspondent's allusions to "priestcraft" and "homilies" seem to warrant the interpretation that he seeks for no light on the moral aspect of the question at issue, having decided that for himself. That he was at perfect liberty to do, of course, and, were this journal published solely for his edification, the relations of morality to the practice of medicine would never again be touched upon in its columns. Such does not happen to be the case, however; and, since there is good reason to believe that, with very few exceptions, the members of our profession entertain the most settled purpose to make their practice conform to the requirements of a conscientious sense of duty, the journal, while not seeking to control any man's conscience, and still less to decry him into the toils of "priestcraft," feels itself perfectly warranted in dealing with medical matters in their moral as well as their material bearings, even at the risk of finding its observations treated as "homilies and anathemus."

There is one thing, however, that we shall not do: and that is, to give information as to the ways and means of preventing conception, however many women there may be who "bear children more frequently than is for the good of any and all parties concerned." Neither shall we suffer the journal to be drawn into any discussion of the matter on the basis laid down by our correspondent.

THE MEDICAL STUDENT'S SUMMER WORK.

In view of the work still before them, in order that they may acquit themselves with credit when they come up for examination, it is scarcely to be supposed that many of our medi-
MINOR PARAGRAPHS.

CHOLERA.

During the week that has elapsed since the account given in our last issue was prepared, the disease has spread in a number of directions in Egypt, but the mortality at Danteia, the scene of its first outbreak, has rather diminished. It has reached Cairo, and a few doubtful cases are reported from Alexandria, which latter place the sanitary officials decline to isolate, perhaps because a number of the cordons already established have become infected and therefore practically useless. The Spanish government seems to have entered on the policy toward England that was alluded to last week, having, it is announced, instituted a system of compulsory sanitary inspection of all vessels arriving at Spanish ports from England. The Turkish government has revived the regulations enforced in 1867, quarantining all vessels from Egypt arriving at Smyrna and Beirut, and absolutely closing all other Turkish Mediterranean ports to them. At Gibraltar a quarantine of twenty-one days on all arrivals from Egypt is in force.

At San Francisco a strict enforcement of quarantine has been ordered against all vessels that have cleared from or touched at ports infected with cholera, small-pox, or yellow fever. A bark from Egypt, laden with rags, is reported to have proceeded to New Haven, Conn., after having been discharged from quarantine at New York. The New Haven authorities prohibited any communication between the vessel and the shore for a time.

M. Pasteur has proposed an organized investigation of the nature and origin of the outbreak in Egypt, and has asked the British Foreign Secretary for facilities in carrying out the plan.

YELLOW FEVER.

It turns out that the steamship City of Mexico, which has arrived at this port from Havana, had had no cases of yellow fever on board, as it was supposed she had. The health authorities of the port of New York have been informed by the Surgeon-General of the Marine-Hospital Service that the steamship City of Alexandria was bound here from Vera Cruz, after touching at Havana on Saturday, and leaving three patients with the disease there, the vessel was subjected to a rigid examination on her arrival, but it was found that there had been no cases of the disease on board during the trip from Havana. The cargo is being discharged at Upper Quarantine, and the vessel will then be cleansed and fumigated.

GLANDERS IN ILLINOIS.

It will be a source of great regret if the report proves true that the State Veterinarian of Illinois is meeting with legal opposition to his energetic and enlightened manner of dealing with the epidemic. By the efforts of the State Board of Health he had been clothed with powers that were thought to be equal to the occasion, namely, an extension of the provisions of the Pleuro-pneumonia Act to cover the matter of glanders; and a sufficient appropriation had been placed at his disposal. As the disease is said to exist in nineteen counties, no factsious opposition to its prompt suppression ought to be tolerated.

MAGICAL MEDICINE IN MICHIGAN.

An inquest held on the body of a child that was lately found dead in Michigan brought out the following story of the way in which a quack had undertaken to cure the child of epilepsy:

"He put something in a jug, kept it in the stove over nine
days, and, after wiring the cork in the jug, sunk it in the river. He also wrote two pages of note-paper full, folded it in a three-cornered shape, representing, as he said, the Trinity, sewed it in a three-cornered bag, and, attaching strings to it, tied the same around the child's neck, where it was kept 'till it died. His 'magic cure' was written in German, and the following is a literal translation: 'William John Warner will regain his health in the name of the Lord, God Father, God Son, and God Holy Ghost. Amen. ¶ ¶ ¶ N. I. 

(A translated Jesus of Nazareth, Nazarene Jesus.) Beelzebub and all the bad spirits, I forbid you my bedstead, in the name of God, my house, and also my yard; I forbid you, in the name of the Holy Trinity, my blood and flesh, my body and soul. I forbid you as many times as we have nail-holes in my house, as many times as drops in the water, as many times as leaves on the trees, as many times as stars in the heavens, until the last days of judgment arrives, and Mary, the mother of God, gives birth to her second son. In the name of God Father, God Son, and God Holy Ghost. Amen. Thou art fiend, thou has taken hold of our William John. Get thee hence. Let the worms go out of your body, and your marrow and bones are [sic] again. I beseech you, for the sake of the five wounds of Jesus Christ, get out this very hour.'

A CHINESE DISEASE IN BRITISH COLUMBIA.

A report from Victoria, B. C., states that many Chinamen were lately landed there suffering from a strange and specially fatal form of disease, 'the result,' says the dispatch, somewhat dogmatically, 'of an almost exclusive consumption of decomposed vegetable food.' The onset is said to be characterized by pain and loss of power in the feet. The paralytic condition creeps up to the trunk, blebs appear about the mouth, and symptoms of blood poisoning ensue.

FEES FOR CORONERS' AUTOPSIES.

On Tuesday of this week an inquest on the body of a child that had died in Paterson, N. J., from opium poisoning, it was thought, was brought to a standstill by the coroner's inability to find a physician who was willing to make the autopsy for ten dollars. It seems that the Board of Freeholders will pay no more than that sum. The suspected poisoning is attributed to an apothecary's error in renewing a lot of powders that had been prescribed by Dr. E. J. Marsh.

BRUTALITY IN A LUNATIC ASYLUM.

The asylum at Norristown, Pa., was lately the scene, according to the newspapers, of an unusually brutal assault committed upon a patient by an attendant. Two accounts of the affair are given, the superintendent alleging that the patient first struck the attendant. Be this as it may, it is difficult to understand why no steps were taken to secure the attendant's legal punishment instead of simply dismissing him.

AN OUTBREAK OF ANTI-VIVISECTION BIGOTRY IN PARIS.

According to our Paris exchanges, a scene took place on the 22d of May at Professor Brown-Séquard's amphitheatre at the College of France. Toward the close of his practical course, M. Brown-Séquard had begun a series of experimental demonstrations to illustrate the new facts of which he had previously spoken. It is well known that he has discovered that general analgesia, without loss of tactile sensibility, may be produced by irritating the laryngeal mucous membrane with carbonic acid or the vapor of chloroform, certain precautions being taken to prevent the entrance of these substances into the lungs. He was preparing to test the sensibility in a little monkey that had been subjected to an experiment of this sort three days before. A few minutes before the lecture, he was about to cut the sutures in a wound near the larynx in this monkey, when a young woman gave him a blow on the fingers with her umbrella. Being asked to withdraw, the girl refused to do so, declaring that by virtue of the Grammont law she had the right to prevent any cruelty to an animal in a public place. M. Brown-Séquard resumed his manipulation, and the woman tried to strike him again, but this time her umbrella was wrested from her before she could give the blow. A policeman was called, and took her before the commissioner of the locality, where a complaint was entered against her by two witnesses of the scene.

The story got into the newspapers that M. Brown-Séquard was intending to cut the vocal cords, "to prevent the poor beast's frightful cries," whereas that was the last thing he would have thought of doing, since to assure himself whether the monkey could feel pain was the very object he had in view. Moreover, the monkey had not cried at all, although its sensibility had been regained.

As a counterpart to this incident, the following Tuesday, M. Brown-Séquard having taken the utility of vivisections as the subject of his lecture, the amphitheatre proved too small to hold his hearers, and he unrolled his theme before a select audience, the only interruptions being those occasioned by repeated applause and evident marks of the most active sympathy.

THE LYMPHATIC RADICLES AND THE CAPILLARY BLOOD-VESSELS.

The well-known anatomist, M. Sappey, lately made a most interesting communication to the French Academy of Sciences in which he described a method of investigation that he had resorted to in studying the question of a communication between the capillary blood-vessels and the radicles of the lymphatic system. We find the following abstract of M. Sappey's note in the "Gazette hebdomadaire de médecine et de chirurgie": The process consists in imparting a straw-color to the transparent walls of the "capillitules" and the lacuna, so as to make them plainly visible. This is accomplished by filling their cavities with a multitude of organisms belonging to the lowest class of cryptogams. If microsia proliferate rapidly in the lymph plasma, they proliferate no less rapidly and abundantly in the blood plasma. To make their presence answer the purpose, it was important that they should show themselves in the lymphatic capillaries exclusively, and not at all in the capillary blood-vessels. This result was secured by injecting an acidulated liquid into the blood-vessels, in sufficient quantity to drive out their contents; in other words, a solution in which microphytes cannot proliferate was substituted for the blood plasma so favorable for their development. Under these conditions no trace of a microzyma is observed in the capillary blood-vessels. On the other hand, the lymphatic radicles, filled with colored cells, appear alone in the field, and they are shown with such nicety that it becomes easy to study them collectively, in their minutest details, and in all their infinite varieties. Studying the question in this way, M. Sappey reaches the conclusion that we cannot admit a communication between the two sets of vessels, but that the lymphatics are everywhere closed at their origin, any penetration of blood plasma into the lymphatic radicles being the mere result of transudation or of capillarity, with some slight modifications.
THE COMMITMENT OF LUNATICS.

The carefully prepared bills on lunacy legislation, which were brought before the Legislatures of New York and Pennsylvania during last winter, show how aroused public sentiment has become to the need of a change in the present modes of commitment and discharge. The fact that neither the lunacy reform bill nor that relating to the coroner's office passed the Legislature of this State does not show any weakness in the bills themselves, but merely demonstrates the unwillingness of politicians to carry through measures which are absolutely non-partisan and from which no pecuniary gain can be made. It is noticeable that in France there is at present an agitation in favor of a change in the mode of commitments of the insane. Since 1838 it has been possible to confine any person in an asylum on the simple certificate of a physician. This easy mode of disposing of persons objectionable for any reason to their friends or relatives has naturally led to abuses. The Minister of the Interior has now recommended changes in the law so that such a commitment can only last until the proper legal officer has examined into the case. When the commitment is made, the physician must furnish a full report of the case, detailing the symptoms and progress of the malady. This report, together with a further one made by the Superintendent of the Asylum, is to be forwarded to the Prefect of the Department and to the Procureur de la République for the Arrondissement where the patient resides. This official, assisted by a physician chosen by himself, must within three days make a personal examination of the person said to be insane, and his written order is the warrant for the further detention of the patient or for his discharge. The whole proceeding must be completed within a month, so that, if the patient is declared to be sane, he shall not be deprived of his liberty for any length of time.

PARALYSIS IN CONNECTION WITH THE LOSS OF A LIMB.

M. BocKdon, of Paris, has devoted a good deal of study to the question of the effects of total cessation of functional activity of a part, as exemplified in cases of the loss of a limb by amputation, on the motor zone of the cerebral cortex. At a recent meeting of the Académie de médecine he added another observation to the six that he had previously embodied in a memoir on the subject, all going to show that atrophy of the superior part of the motor zone may be the result. In this seventh case, that of a person who had lost an arm, there was paralysis of the leg on the same side. The paralysis was slow in its development, and was not accompanied by any cerebral symptom, whereas M. Bourdon suggests that it may have been due to an extension of the atrophic process. Such a feature was not observed in the six other cases, and, as the patient was advanced in years, it was remarked that cerebral atrophy, an affection somewhat common in old people, might have development without any connection with the loss of the limb.

THE RESPONSIBILITY OF INSANE CRIMINALS.

Attaching all due weight to the doctrine of moral insanity as affecting responsibility for criminal acts, and utterly denying the justice of the old legal test of a knowledge of right and wrong, many reflecting persons are coming more and more to look upon the majority of the insane as to some extent responsible for their conduct, since they are manifestly controlled in some measure by ordinary impulses acting in opposition to their insane propensities. We are glad to see that such considerations as these were brought forward by Dr. Everts, of Cincinnati, in a paper read before the recent meeting of the American Association of Medical Superintendents of Asylums for the Insane, held in Providence. The knotty point to be settled in individual instances is as to the degree of responsibility. No greater field of usefulness seems to us to open before our alienists than the investigation of this problem.

A NEW JOURNAL OF PEDIATRICS.

The new "Revue mensuelle des maladies de l'enfance," the issue of which was begun this year, constitutes a most important addition to our periodical literature of the specialties. Its scope includes hygiene, medicine, surgery, and orthopedics. It is published by M. Laurenweyer, of Paris, and edited by M. Cadet de Gassicourt and M. de Saint-Germain, assisted by MM. Abadie, Archambault, Balzer, Bergeron, Blache, Desrozilles, D'Heilly, Fienzal, Guéniot, Labrie, Lannelongue, Moizard, Quimus, Sevestre, Jules Simon, and Tarnier, M. Pierre J. Mercier acting as secretary of the staff. Each monthly number consists of forty-eight octavo pages.

The July number contains an article on feeding by means of the stomach-tube after tracheotomy, a paper on the diagnosis of retro-pharyngeal and congestive abscesses, and a report of the nursery department of the Hôpital de la Conception at Marseille. Besides these formal contributions, there are several important abstracts. The "Revue" makes a handsome appearance, and can scarcely fail, we should think, to find favor with the profession in France.

NEWS ITEMS.

A SUSPECTED CHARITY.—An organization styled the New York Medical Aid and Relief Society for Destitute and Sick Women and Children, of which an eclectic practitioner, one Dr. W. J. Bryan, seems to be the active official, is likely to be subjected to a rigid investigation by the State Board of Charities. The most noteworthy "irregularity" alleged against the concern is that of using men's names in its list of trustees without authority.

AN ALLEGED ABORTIONIST.—Dr. Charles A. Heintze, of Philadelphia, against whom his wife has brought charges of desertion and adultery, is also charged by her with having led the career of a criminal abortionist. He is said to be a graduate of the University of Berlin, and also of a homoeopathic college in this country.

AN AMATEUR ABORTIONIST.—A man now under arrest at Waterbury, Conn., charged with having caused the death of his sister by malpractice, is described as "a peddler with a fondness for medical reading."

THE UNIVERSITY OF MARYLAND.—According to the "Maryland Medical Journal," Dr. L. Ernest Nele has been appointed Demonstrator of Obstetrics.

A MALIGNANT OUTBREAK OF MEASLES is reported as having appeared at St. Mary's Industrial School for Boys, near Baltimore, causing the death of ten of the four hundred and twenty inmates in the course of five days.

THE AMERICAN OPHTALMOLOGICAL SOCIETY.—At the annual meeting, held at the Hotel Kauterskill, at the Catskill Mountains, on Tuesday, the 17th inst., the following-named gentlemen were elected officers for the ensuing year: President, Dr. Charles H. Burnett, of Philadelphia; Vice-President, Dr. J. S. Prout, of Brooklyn; Secretary and Treasurer, Dr. J. J. B. Verryme, of New Bedford, Mass.; Committee on Membership, Dr. John Green, of St. Louis; Dr. H. G. Miller, of Providence; and Dr. Arthur Mathewson, of Brooklyn.
July 21, 1883.] PROCEEDINGS OF SOCIETIES. 73

St. Peter's Hospital, Albany.—We learn from the "Medical Annals" that Dr. George S. Munson has been appointed one of the ophthalmic and aural surgeons to the hospital.

MEMENTOS OF JOSEPH PRIESTLEY.—The astronomical, philosophical, and chemical apparatus used by Dr. Priestley have been given to the Smithsonian Institution at Washington.

CHINESE MEDICAL STUDENTS.—The "British Medical Journal" states that the Emperor of China has received the permission of the government of India to send a certain number of youths to India with a view to their studying European medicine and surgery at the medical colleges.

The Staten Island Epidemic of Pseudo-pneumonia is said to have killed over two hundred cattle during the last three weeks.

The Harvard Veterinary Hospital, in Boston, will probably be completed about the 1st of August.

The Registrar of the Royal College of Physicians, Dr. H. A. Pitman, is reported to have been knighted.

OBITUARY NOTES.

The Rev. Charles W., Calhoun, M. D., of Syria.—Dr. Calhoun, a graduate of Bellevue Hospital Medical College, and a medical missionary under the Presbyterian Board of Foreign Missions, has just died at Shevafat, Mount Lebanon, Syria. About a year since, the Turkish authorities at Tripoli pulled down the sign over his office, and since then he has practiced mainly among the villages in the surrounding country. The American Minister at Constantinople has demanded redress for the insult, and the news of this action came almost at the same moment with the tidings of Dr. Calhoun's death. Being a native of Syria, Dr. Calhoun had an intimate acquaintance with the language and habits of the people, so that he had very easy access to their homes. He was much beloved by his associates among the missionaries, and it will be hard to fill his place.

Benjamin Musser, M. D., of Strasburg, Pa.—Dr. Musser died last Saturday, in his sixty-third year. His progenitors, for several generations back, were physicians, and a son of his is now a well-known practitioner in Philadelphia. The deceased gentleman was a member of the Medical Society of the State of Pennsylvania.

Thomas F. Scott, M. D., of Petersburg, Va.—Dr. Scott died at his home in Petersburg on Wednesday, the 11th inst., at the age of eighty. He was a nephew of General Winfield Scott, a member of the Virginia State Medical Society, and a man of reputation beyond the limits of his State.

Proceedings of Societies.

NEW YORK SOCIETY OF GERMAN PHYSICIANS.

A stated meeting was held March 24, 1882, Dr. Emil Gruening in the chair.

OSTEOPLASTIC EXCISION OF THE SUPERIOR MAXILLA.—Dr. Gerster introduced an elderly woman, on whom he had performed this operation for infra-orbital neuralgia. The patient complained frequently of pain in different parts of the body, but the left infra-orbital region was the site of her chief trouble.

At one time she had all her teeth extracted, but obtained no relief. On examination, the doctor found a fistula leading into the antrum; the mucous lining of this cavity appeared normal. With the exception of slight modifications, the operation was done in the same manner as the one reported in a recent number of these transactions.

The drainage-tube in the spheno-maxillary fossa was dispensed with and primary union secured.

The patient subsequently complained of pain in the right nostril.

Dr. A. Jacobi said that severe and persistent neuralgia might indicate a central lesion, infra-orbital neuralgia being occasionally the first symptom of disease of the cord.

An operation should not be resorted to in cases admitting of much doubt as to the peripheral or central origin of the pain.

Dr. G. W. Jacoby stated that he saw this patient at the German Dispensary, when she complained of neuralgia in both sides of the face, which he attributed to constitutional disease. He met her again after the operation, but did not find her improved, according to her statement.

FOREIGN BODY IN THE FOREARM.—Dr. Gerster introduced a young man who had received a stab with a knife in the volar aspect of the forearm near the carpus, in the autumn of 1880.

The wound healed in a short time, and gave no trouble until a week ago, when the arm became painful. An incision was made and a knife-blade 3" long removed, which the man, who was a laborer, had carried in his arm two years without his knowledge and without complaint. Dr. Gerster remarked that such cases proved to him the truth of the assertion that simple mechanical irritation of sound tissue would not produce inflammation. Irritation must always be accompanied by infection in order to produce inflammation.

Dr. Jacobi remarked that he was not prepared to accept this theory of inflammation. A foreign body, taking a position parallel to the fibers of the tissue in which it was imbedded, might not be a source of active inflammation, but, when introduced transversely, so as to irritate the tissues, an inflammatory reaction would ensue without the agency of infectious matter.

Dr. Gerster would explain these facts by assuming the presence of infectious matter in the body of some individuals.

Dr. Jacobi said he was familiar with this theory, and that no convincing testimony had yet been offered in its favor.

DIABETES.—Dr. B. Scharlat had had under his care a man, sixty years old, whose urine, in October, 1880, showed a specific gravity of 1.030, and contained a high percentage of sugar. The patient subsisted on a strict milk diet for six weeks, after which a specific gravity of 1.010 was noted, and not a trace of sugar found. From December 24, 1880, to March 12, 1882, on which day the last test was made, the urine was absolutely free from sugar, although the patient during that time had partaken liberally of all kinds of food and drink.

Dr. Jacobi also remembered two or three cases in which the sugar disappeared after a strict milk diet. No medicines were administered at the time.

LEPTOTHRIS IN TONSILLAR CONCRETIONS.—Dr. E. Gruening had recently cut into a swelling, located at the inner angle of the eye, in a girl fourteen years of age, and removed therefrom about ten small, hard stones, which contained numerous elements of leptothriss when examined under a microscope. He remembered having seen eight such cases in his practice.

Leptothrix could readily get into the eye with the saliva. The tonsils and pharyngeal mucous membrane frequently contained such concretions, consisting, according to the books, of epithelium, lime, and cholesterol.

Dr. Gruening examined a large number of these stones, taken from fifty different individuals, and in every specimen he
found the matrix and mycelium of leptothrix. He thought, therefore, that the follicular pharyngitis of Mackenzie, or the pharyngeal seborrhoea of Storck, was nothing more than an inva-
sion of leptothrix into the follicles of the mucous membrane.  
[For a complete account of these investigations, vide "Ar-
chives of Laryngology," April, 1882.]

Dr. Jacob said that stones were found in follicles which had been
inflamed, and the semi-solid contents of such a follicle gradu-
ally became hard. Such stones might contain the ele-
ments of leptothrix, but he did not think that their formation
was entirely due to this form of algae, and would refer to pre-
putial stones as a direct evidence of the contrary.

RENAL CALCULI IN THE NEW-BORN.—Reported by Dr. A. Ja-
com.—In one case the child was only ten days old when symp-
toms of difficult micturition were noticed, and in another case
an infant passed blood soon after birth—the first urine being
vomited forty-eight hours later—and a reddish, gritty mass was
found in the diapers. In both cases the bladder was examined
for stone, etc. The doctor stated that he had detected six cases
of congenital renal calculi in forty autopsies, and believed that
many cases of so-called intestinal colic occurring in children
were in truth cases of renal colic. The passage of a calculus
was frequently accompanied by haemorrhage and followed by
secondary nephritis.

A STATED meeting was held April 28, 1882, Dr. E. F. Schwed-
ler in the chair.

GOUT.—Dr. H. G. Klotz introduced a man, fifty-two years
old, whose fingers were studded with a number of tumors vary-
ing in size. The patient said he had been a moderate drinker,
and had never had syphilis. He remembered that he had been
severely sick with typhoid fever many years before, and in 1863
suffered from articular rheumatism, uncomplicated with cardiac
disease. During the past fifteen years he had been employed in
a gas-house, and he first noticed a swelling of the phalangeal
joints in 1873. At the present time the tumors varied in size
from that of a filbert to that of a walnut; they were soft to the
touch, and consisted of a firm capsule connected with the tendon
sheaths, surrounding a whitish, putty-like mass, which was
composed, as shown by the microscope, of fine needles and very
little fat. The patient's condition had not improved much un-
der the administration of colchicum, with potassium iodide and
sodium salicylate.

Dr. A. G. Gerster alluded to a similar intractable case, at
one time under his care, in the person of a man of twenty-six,
an immoderate beer drinker, whose parents had likewise suf-
fered from gout. He became first afflicted with articular rheu-
matism in 1851, and suffered much from effusion into the knee
and elbow joints. Even the tendon sheaths and muscular inser-
tions were involved, and occasionally all the smaller joints be-
came tamedd. No improvement followed the administration
of internal remedies. When mercurous iodide was given, the
severity of the symptoms seemed to increase; finally, the em-
ployment of baths and general massage was followed by slight
improvement, although the joints still continue to be trouble-
some.

LEAD PARALYSIS.—A patient was presented by Dr. Seeske.
He was a man of fifty. All the extensor muscles were in-
olved, the supinator muscles being free; there was marked
thenar atrophy. After two sittings with the faradalic current,
great improvement was noticed. Hitzig claimed to have found
intumesence of the blood-vessels in saturnine paralysis; the
muscles usually showed degenerative reaction in response to the
faradalic current, and in some cases degeneration of the large
cells in the anterior horn had been observed.

Table showing the difference between Lead Paralysis and kindred Nerv
ous Disorders.

case. |

Dr. H. J. Garrigues exhibited a specimen of Abnormal Dis-
position of the Placenta.

This case was described by Dr. Garrigues in "The New

A KOPROLITH was presented by Dr. A. Jacob. The speci-
men was passed from the bowels of a woman who had suffered
for about one year from chronic diarrhoea. She had frequent
attacks of colic, associated with a painful swelling in the region
of the gall-bladder and a yellow discoloration of the skin. Perihe-
patitis was suspected, and the patient was directed to abstain
for a time from all nourishment except milk and stimulants.
Finally the patient died, after having suffered numerous attacks
of chills with high temperature, probably due to hepatic ab-
scess. An autopsy was not made. The specimen presented was
as large as a champagne cork, very light and brittle; it was found
to be insoluble in alcohol and ether, slightly soluble in alkaline
liquids, and readily soluble in acids; it consisted of casein, salts,
very little fat, and no cholesterol, and was in all probability a
formation from the milk taken in large quantities by the pa-
tient.

A DETACHED FINGER AND TENDON.—Dr. Balsir showed a
finger, with the tendons of the flexor profundus and sublimis
attached, which was severed from the hand of a man who en-
davored to scale an iron gate and got caught on a projecting
point. The tendons were about 9" long. The wound was not
painful, and healed promptly. Billroth had reported such a case.

Dr. Kudlow referred to a similar injury, treated some years
ago at the Chambers Street Hospital.

FALSE NEUROMATA.—Dr. A. G. Gerster showed two such
tumors of small size. The one was removed from the lateral
aspect of the fossa poplitea, the other from the anterior aspect
of the thigh, a little above the patella—their microscopic struc-
ture being that of a fibroma. He also presented a papilloma of
the rectum, taken from a woman on whom he had operated for
haemorrhoidal tumors. The day after the operation the rectum
was cleansed with an injection of lukewarm water, whereupon
the growth made its exit and was removed by ligation and
knife. It was found to consist of connective tissue and cylin-
drated epithelium.

Dr. Jacob remarked that adenomata of the rectum were
often met with in children, and frequently overlooked, as they
produced little pain or haemorrhage.

URTICARIA FOLLOWING VACCINATION.—Dr. Mihaylov re-
ported the case of a child whom he had vaccinated, and who
subsequently became afflicted with urticaria, the eruption
making its appearance on the tenth day and persisting for four
days.

Another case was that of an elderly woman, with intermit-
tent urticaria and high fever, accompanied by profuse perspira-
tion. The patient had three such attacks, the second on the
third day, the last one on the sixth day, the disease being
probably checked by a large dose of quinine, which was given after the third attack. A similar seizure, some months later, was promptly relieved by a single dose of quinine.

Dr. Klotz, referring to a recent publication by Behrend, of Berlin, on cutaneous eruptions following vaccination, thought that they, as well as such forms of exanthema as followed the administration of certain drugs, might be explained by assuming an idiosyncrasy.

A. Caille, M. D.,
Secretary pro tem.

A stated meeting was held May 26, 1882, Dr. Balser in the chair.

Dr. H. S. Oppenheim introduced an old man who had suffered Dislocation of the Lens of the left eye fifteen years previously, and was now afflicted with acute glaucoma. The lens had found its way into the pupil, and was there held fast. The eye was painful and injected, intracranial pressure was increased, iritis was present, and perception of light was almost nil.

The patient declining all operative interference, Dr. Oppenheim simply applied atropine, whereupon the lens became free and floated into the vitreous. Some weeks later a similar attack was treated in the same manner. During the present and last attack atropine was instilled as before, and the patient directed to lie face downward, in which position the lens gravitated into the anterior chamber and was there retained by contracting the pupil with eserine, and extracted in the usual manner. After the wound had healed, the eye was found clear and free from pain; the patient was able to see 7-.

The ophtalmoscope revealed retinitis pigmentosa.

Dr. Greuning remarked that in this case atropine was indicated. By dilating the pupil, the lens would become free and cease to be a source of irritation.

Laryngeal Syphilis.—Dr. T. Taszyk described the larynx of a negro who cut his throat during an attack of severe dyspnoea in consequence of syphilitic necrosis of the interior of the larynx.

The autopsy showed perichondritis of the margin of the epiglottis, with ulceration of the cricoid and thyroid cartilages, and hypertrophy of the true and false vocal cords.

Dr. Jacott thought it was a case of acute chondritis, in which tracheotomy was indicated.

Foreign Bodies in the Intestines.—Dr. S. Korn reported the case of a melancholy female with symptoms of intestinal obstruction and general peritonitis. She improved under treatment, and subsequently suffered five similar attacks during the course of five weeks. After her last illness, she passed from her bowels three teaspooths which she had swallowed.

A similar case was reported some years ago by Mr. Poland, of London.

Elephantiasis Vulva.—Dr. F. Mendé exhibited this specimen, involving both labia and clitoris of a mulatto woman twenty-four years old. The patient first noticed a swelling after her second confinement, and after the birth of her third child the parts became ulcerated and painful to such a degree as to produce in the patient a tendency to synphomania.

The removal of hypertrophic labia might be accomplished by the thermo-cautery, the galvano-cautery, or the knife. Schröder reported a case in which he removed the mass from below and applied sutures immediately as he went along, without obtaining primary union, however.

In operating, Dr. Mendé transfixed the hypertrophic tissues with three large needles, underneath which he applied a firm elastic ligature. After removing the mass with a knife, he secured twelve vessels and applied twelve sutures. The woman was four months pregnant at the time of operation.

Elephantiasis vulve was not at all rare, but the patients did not readily submit to an operation, as the swelling did not, as a rule, interfere with parturition. Irritation from a chancroid sore had been accused of producing hypertrophy of the tissues.

Dr. Scharlaw said that he had a similar case under observation some years ago. The tumor was very large, but offered no impediment to the passage of a child.

Spinal Menigitis.—Dr. Jacott reported such a case in the person of an elderly lady who had suffered much anxiety and mental strain from domestic trouble. Some three weeks ago she received a message by telegraph which affected her very much, and, while walking on the street, became unconscious and fell to the ground. She was carried home, and remained in a state of great excitement for four days. She tore her hair, and became so violent as to require large doses of chloral hydrate and potassium bromide. She got better, but had no remembrance of the four days of severe sickness.

An examination at the present time showed the following conditions: Pupils of equal size; tongue and uvula not deflected; sensibility perfect throughout the body; mobility of the left arm normal; severe tremor of all other extremities. The patient complained of numbness in the feet, and pressure on the spinous processes was painful. The temperature was 101° F.

Dr. Jacott believed it to be a case of general spinal meningitis, induced, probably, by great mental excitement.

Dr. Szesssz made inquiry as to the presence of ankle clonus in this case.

Dr. Jacott replied that it was impossible for him to isolate this symptom, almost all the muscles of the body being in continual motion.

Dr. Szesssz remarked that the presence of ankle clonus, in connection with the symptoms stated above, would strongly indicate paralysis of the lateral cords.

Periodic Albuminuria.—Dr. Scharlaw gave the history of a woman, thirty-three years old, who, four years ago, was taken sick with diphtheria and rheumatic arthritis accompanied by albuminuria, and recovered, with slight insufficiency of the mitral valve and hypertrophy of the left ventricle.

This lady had given birth to three healthy children in the first years of her marriage, and subsequently became pregnant ten times, the fetus never again attaining maturity. About the second month of each pregnancy albumin appeared in the urine, remaining until some weeks after the premature birth of the dead and macerated child, which usually took place in seven or eight months. Of late, however, this patient's water always contained albumin, but no renal elements.

The woman was not syphilitic. The placenta and fetus were repeatedly examined, and nothing noteworthy was detected. Dr. Scharlaw, notwithstanding the most thorough examination, had not been able to determine the cause for the periodic albuminuria and interrupted pregnancy.

Reflex Neuroses.—Dr. Mendé reported two such cases. He examined a lady who had suffered for many years from severe headache, which had not yielded to the treatment of several of our best physicians. He found a bilateral fissure of the cervix uteri, together with an indurated and painful spot in the anterior wall of the vagina. He applied one pole of the constant battery to this place, and, after a few sittings, the tissues became soft and the patient's headache was gone. The second case was that of a woman of forty, whose headache was cured by the application of a suitable ointment to relieve a retrodissected wound.

Dr. Gaimouques stated that he had had a similar experience in his practice.

Dr. Greuning remarked that he had met with quite a number of neuroses in and about the eye ex causa uterina.

A. Caille, M. D.,
Secretary pro tem.
OBSTETRICAL SOCIETY OF PHILADELPHIA.

(Concluded from page 50.)

Dr. W. H. H. Githens stated that on June 18, 1878, Dr. Albert H. Smith had operated upon Mrs. M. for the restoration of a lacerated cervix; and on July 10th of the same year he performed perimorbilli, both operations proving successful. On June 19, 1879, a year and a day after the first operation, he (Dr. Githens) delivered her of a boy at full term, the labor being uneventful. In no case was there any fear of either cervix or perineum occurring.

Dr. E. E. Montgomery remarked that, as regarded the question of sterility resulting as a consequence of the restoration of a lacerated cervix, he had been operating since 1879, and five of the patients he had operated upon had since become pregnant. The first patient upon whom he operated became pregnant latently, but aborted; as she had desired not to become pregnant, and was anxious that an abortion should occur, he believed that it had been artificially induced. Another patient, operated upon in 1880, had been delivered in January, 1883, without accident. A patient operated upon in 1879 was now four months advanced in pregnancy; before the operation she had aborted at three months; this accident was apparently consequent on the existence of the laceration. Of these five cases, two were lacerations of long standing, and three were recent.

The President had operated in one case of nine years' standing. During the first two years of that time the patient had two miscarriages, and then remained sterile for seven years. The operation was performed eleven months ago, and she was now two months advanced in pregnancy.

Dr. Albert H. Smith had heard Dr. Baer's paper with pleasure. The general impression in this city was that sterility was a consequence of the injury, and a large proportion of the patients operated on by him had soon become pregnant after the operation. The fear of the recurrence of the accident prevented pregnancy in many cases, as means were used to avoid that condition. Improved general health and local comfort were a result in a majority of the cases, even where pregnancy did not occur. He would like to hear Dr. Baer's experience about the existence of obstinate nausea in pregnancies after operation in long-standing cases, accompanied with an enlarged and hardened condition of the cervix. It had been so with him. As regards the results of labor, there had been no tendency to re-laceration in the same position. He used inhalations of chloroform and hot-water douches in such cases, and did not rupture the membranes early; he also prevented the patient from bearing down, and by these means secured a slow and safe labor. He was sorry to hear that Dr. Baer had no confidence in the power of the operation to reduce the size of a hyperplastic uterus. He had seen cases of so-called subinvolution of the uterus in which, after the complete failure of local means—such as iodine, silver nitrate, etc.—the organ was reduced to one third of its bulk by operating upon a laceration of the cervix. The rapidity with which the ultimate result of reduction in size was reached was in proportion to the time that had elapsed since the injury.

When the cervix was much hypertrophied, and ectropion existed—such a cervix as would formerly have been called cancerous, and would have been anatumated—the stitches should be left in a long time. If they were removed too soon, there was a proneness to gaping, a sort of ectropion or sprouting. This would not happen if the sutures were allowed to remain thirty to forty days.

Dr. William Goodell regretted that he had been too late to hear Dr. Baer's paper. With reference to the question of the influence of the operation in causing sterility, he thought it did have such an influence. He had operated in one hundred and sixty-nine cases, and had only known of seven patients who had since become pregnant. There had probably been more, as the patients had passed away from his knowledge, and he had never heard of them again, for he did not practice obstetrics outside of the Preston Retreat. In two of the seven cases a second operation was required, but it was slight. In one case not the slightest change occurred in the form of the os. As regarded the effect of the operation in preventing cancer, he believed it fully, both from experience and from a priori reasoning. He had seen but two cases of epithelial cancer in women who had not borne children. In fact, his experience had been that the greater the number of children, the greater the liability to carcinomatous degeneration, and often the notch of a previous laceration was seen in the cancer. If carcinoma was, as we believed, a local disease at its beginning, what more probable cause could we have than such an irritating sore as a bad laceration of the cervix. In more than one case his principal reason for operating for the restoration of the cervix had been a history of cancer in the family.

Concerning the effect of the operation upon hyperplasia, he believed with both Dr. Smith and Dr. Baer. There was an element of passive congestion, the result of the irritation of the laceration, and, when the cause was removed by the operation, the effect passed away, and a great reduction in the size and weight of the uterus was secured. He believed that preliminary treatment in cases of enlargement with ectropion had a very great effect upon the results of the operation. Applications of iodine, glycerin, and tannin, the use of the very hot douche, and cross-hatching of the enlarged Nabothian glands, had a softening and calming effect. In such cases, if the hard, gristy triangle in the apex of the womb was carefully excised, the tension on the sutures was slight. He generally removed the sutures in about nine days after the operation; in one case, in consequence of circumstances affecting convenience, they were allowed to remain three weeks. When he could secure easy approximation and close coaptation, which was readily done by means of his guiding thread, perfect union was more probable than in any other plastic operation. For his sutures he used the finest possible silver wire; it was drawn to order.

As regarded the results of the operation on various symptoms that were supposed to arise from the presence of the injury, he had experienced the greatest success and great disappointments. In some, local treatment would have answered every purpose. The most expensive present he had ever received from a patient was from one on whom he had performed this operation and relieved, by it, a morbid mental condition that had lasted for years, with great local distress, and inability to walk any distance or to stoop over, as in packing a trunk.

Dr. Smith knew well the value of preliminary treatment, and employed it faithfully, but there was a limit to the endurance of a patient; she could not be kept too long upon her back; and it sometimes became necessary to operate before all that was possible had been accomplished. In some cases there was an unavoidable tension, and in others a friable condition of the tissue which was benefited by leaving the stitches in position. He allowed the patient to attend to her domestic duties with the sutures in situ. In his experience there had been no relation between the number of children and the tendency to carcinomatous degeneration. Such growths had been in women who had had but one or two children only. Cancer of the mammary gland was most common in sterile women, or when children had been few. He had rarely seen cancer in its early stages in an enlarged cervix with ectropion, but, on the contrary, in unnaturally small cervixes.

Dr. Wharton Sextler had three patients who had been
operated upon for lacerated cervix, one of them by Dr. Goodell. All of them had since become pregnant.

Dr. Montgomery remarked that one sixth of the patients he had operated upon (within four years) had since become pregnant. He thought Dr. Smith's suggestion an over true one. As the injury was the result of pregnancy, the risk must not be taken again. In the Philadelphia Hospital he had found cancer of the uterus most common after numerous labors. The same rule had held good in mammalian cancer; it had been most common after frequent nursing. Uterine hyperplasia was reduced by operating on the torn cervix. He had operated with this result in view in cases of so-called subinvolution. Dr. — divided the cervix and removed a wedge-shaped piece, reuniting the wound, as a remedy for this condition.

Dr. B. Bates had performed twenty-three operations, and had two pregnancies occur afterward. He had had under his care seven cases of uterine carcinoma, and in all of them cervical laceration coexisted. The number of children varied from one to several.

Dr. Baer, in closing the discussion, remarked that, in answer to a letter of inquiry to the husband of a patient upon whom he had operated to restore the cervix, he received one in which the idea of another pregnancy was scouted with disdain. He had not observed that more nausea was present in pregnancies following the operation, but he had not had a case of long standing in which pregnancy had occurred as yet. He thought Dr. Smith agreed with him fully regarding reduction in size of an old hyperplastic uterus, whose muscular element had been replaced by connective tissue, when he said that "the rapidity with which the ultimate result of reduction in size was reached is in proportion to the time that had elapsed since the injury." That was exactly the position he (Dr. Baer) had taken in his paper, but he believed the change in the parenchyma of a connective-tissue uterus to be exceedingly slow, if any. The reduction in size occurred in the mucous membrane and the tissues immediately under it, and in the cellular tissue around the organ. Sutures were removed in from eight to twelve days; he thought they ought to be removed as soon as union was solid, because he believed that they had an irritating action after that time. If that action was desired, then they might remain, but that was returning to the old idea of the seton, and, to a certain extent, the operation then ceased to be a plastic one.

W. H. H. Gitthens, M. D., Secretary.

NEW YORK MEDICAL AND SURGICAL SOCIETY.
A STATED MEETING was held February 10, 1888, Dr. T. Gaitland Thomas, President, in the chair.

RENAL CALCULUS.—Dr. H. F. Walker related a case as follows: The patient was a man, about forty-eight years of age, who had suffered periodically for at least ten years with attacks of pain in the left side in the region of the kidney, extending down toward the bladder, and with other symptoms of renal calculus. No calculus, however, had been passed in the urine. The attacks were preceded for two or three days by premonitory symptoms. Various kinds of treatment had been resorted to without much benefit. The last remedy administered was the fluid extract of hydrangea, in doses of a teaspoonful three times daily. After this had been taken for about two or three months the patient suffered from a specially severe attack of renal colic, which lasted for three days, being longer than ordinary, and the pain extended farther down the line of the ureter than usual. There was also nausea and vomiting. The attack was followed by the passage of a calculus about one third the size of a Java coffee-bean, and the patient had since expe-rienced complete relief. In reply to a question by Dr. Post, Dr. Walker said that hydrangea was moderately urticritic. He was led to use it in this case by an article in the "Medical Record," in which the writer stated that it was almost a specific for renal calculi.

The President remarked that he had at present two cases of supposed renal calculi under observation in which he intended to administer hydrangea as a possible means of diagnosis. The first patient, the wife of a physician, had been seen by a specialist in genito-urinary diseases, who had sent her to him on account of a tumor which was perceptible on palpation over the abdominal walls. She had been taken very suddenly with violent pain in the back, which extended down the course of the ureter and the crural nerve. Soon afterward the urine became bloody, and contained a large amount of pus and epithelium from the pelvis of the kidney and the ureter. There were no tube casts. At the time of the occurrence of the sudden attack of pain the patient, or her husband, upon passing the hand over the abdomen, discovered a tumor. The tumor was quite distinct when Dr. Thomas saw the patient, but it was only perceptible in the sitting posture, a fact which he had observed in certain cases of displaced kidney. The presence of blood in the urine in considerable quantity suggested cancer of the kidney, but, as the disease had lasted for two years, and the patient was healthy looking and growing stouter as the disease advanced, he thought malignant disease could be excluded. The affection in the second case had also lasted a long time, and gave a similar history.

Dr. A. C. Post remarked that a stone which had remained in the pelvis of the kidney for some time was usually too large to pass through the ureter.

The President remarked that it was astonishing how large a calculus might remain in the pelvis of the kidney for an indefinite period without giving rise to symptoms. Recently a physician, who died apparently with no other symptoms than gradual wasting away, was found at the autopsy to have a calculus in the pelvis of the kidney as long as the thumb, twice as large, and of the shape of an elephant.

Dr. A. R. Deans remarked that a man once brought to his office a handful of stones, some as large as the end of his finger, and stated that he had often passed them in his urine, and had not suffered in the least.

Dr. A. B. Ball reported further on the case of blood extravasation in the calf of the leg, narrated at a recent meeting of the society. He and Dr. Sands, who saw the case in consultation, had told the patient that the tumor would probably disappear within two weeks, and she would entirely recover. It had now been six weeks, and the patient had just got out of bed for the first time. The blood clot was probably more deeply situated than had been supposed, and, after having become hardened, was slowly undergoing absorption.

TORTICOLLIS.—Dr. Post stated that several years ago he reported a case of torticollis in which he divided the sternocleido-mastoid muscle by an open incision, division of the main bands of the muscle being followed by scarcely any relief whatever; the knife was then introduced more deeply, and the last layer of the muscle cut, with the effect of complete and permanent relief. He recently had a similar case in a girl who had suffered from torticollis in a marked degree from early infancy.

Senna Befida, Tallipes Calculcatus.—Dr. Post mentioned the case of a child, six weeks old, one of twins, that was brought to his clinic lately with a tumor of the spine about the size of a pigeon's egg, developed from the posterior wall of the spinal canal, fluctuating distinctly, which was recognized as spina bifida. The child was also found to have club feet, of the somewhat rare form in which sufficient contraction took place in the
comparatively weak peroneal muscles to flex the foot upon the leg. He directed treatment by manual extension of the foot, which method he had found efficient in a number of cases. If this proved ineffectual, other methods of treatment would be resorted to when the weather was less inclement.

Modified Diphtheria.—Dr. S. O. Van der Ploel lately attended a young man who, having been exposed to membranous group, was suddenly attacked violently at night with sore throat. The temperature rose to 104.5 Fahr., the fuses became reddened, and a large white patch was found upon the tonsils. The patch did not extend back of the tonsils, and was thinner and less highly colored than that usually seen in diphtheria. Fever continued about two days, the exudative patch began to hosen at its edges, and entirely disappeared within four days. There was no swelling of the external glands. The case in many respects resembled group more than diphtheria, and he asked if any of the members had met with such cases, and whether they regarded them as cases of true diphtheria.

Dr. Ball said he had seen a number of such cases—cases in which the throat affection was attended by a rapid and high elevation of the temperature. The exudation usually cleared off within from forty-eight to seventy-two hours. He did not regard them as cases of genuine diphtheria. They probably belonged to the class which the Germans designated as catarrhal diphtheria. So far as he was aware, they never terminated fatally.

Dr. Walker had observed that the color of the throat in these cases was less of a purple hue than belonged to genuine diphtheria; the fever usually commenced sharply, there was a slight chill, and often a headache which was so severe that the patient complained but little of the throat.

The President then read a paper on Intra-uterine Injections in the Treatment of Puerperal Septicemia.*

Complete Destruction of the Kidney by Cancerous Disease: Removal.—The other case to which the President would call attention was that of a patient residing in Connecticut, who gave the following history: She was a married woman, fifty years of age, the mother of six or seven children. She stated that she had attended her twenty-five years ago with Dr. Metalle, and that seven years ago she called at his office on account of a tumor situated on one side of the pelvis, and that he examined it and told her it was a fibrous tumor of the uterus. She had watched the tumor during these seven years, and it gave her no trouble until three months ago. It then began to increase in size, and continued to grow until it filled one half of the abdominal cavity. The patient emaciated and lost strength, and had not been able to leave her bed during the last three months. A great deal of doubt had been entertained by the physicians who had seen her with regard to the character of the tumor. An aspirator-needle had been passed, but no fluid was withdrawn. Dr. Thomas, found, upon examination, that the tumor was of large size, and he was unable to determine whether it was ovarian or whether it was uterine. If it were uterine, it was probably the original fibroid tumor which, according to the patient’s statement, he had diagnosed some years previously, and which had since taken on the character of a sarcoma. As the patient would certainly die within a short time if an operation were not performed, he proceeded to remove the tumor eleven days ago. The moment the abdominal cavity was opened he recognized the fact that the tumor could not be ovarian, for the intestines lay in front of it. The uterus was also found to be entirely disconnected with the tumor. The tumor was evidently deeply situated behind the intestines, and fastened by adhesions, but he was unable, after repeated trials, turning the patient from side to side, to remove the intestines from its surface. The gentlemen present were consulted with regard to the propriety of closing the abdominal wound and abandoning the operation, but the general feeling was that if this were done the patient was doomed to certain death, and, although it was also highly probable that death would take place after removal of the tumor, it was thought better to give the patient the chances of the operation. He then cut through the musculum with the scissors, passed the hand down upon the tumor, gradually swept it upward, came upon the pedicle, which he ligated, and removed the tumor as quickly as possible, the condition of the patient now being very unfavorable. At that time he felt satisfied that the tumor was the kidney. The condition of the patient did not allow of time to search for the other kidney. The cavity was cleaned out, the opening closed, a large drainage-tube inserted, and the patient put to bed. The specimen had been examined microscopically by Dr. Welch, who reported that the mass was composed of cancerous material, but he was unable to determine to what organ it belonged. He could only make out the renal capsule, which was also involved in the disease. Dr. Thomas felt certain, however, that the mass, which weighed six pounds, involved the kidney. The stitches were removed on the ninth day. The patient did very well for forty-eight hours. She then became noisily delirious, and at the end of fifty-six hours she was quite delirious, behaving very much like a person suffering from a low grade of puerperal mania. The pulse was between 160 and 185 before the operation; it had now fallen below 120. The urine had been secreted in amount from 24 to 26 ounces every day. There had been no tendency to suppuration, and no perilumbis, but there had evidently been some septicemic action, the temperature having kept up to 102 and 103, and to-day was 101.6. It had at no time gone above 103. The patient would probably recover from the operation.

Discussion on Dr. Thomas’s paper being in order, Dr. J. W. McLane said that his experience with washing out the uterus had been that, in those cases in which the absorption of the septic material had evidently taken place from within the uterus, the temperature could be reduced by injections into the cavity. But in some cases, undoubtedly septicemic in character, the rapidity of the absorption was very great; a general peritonitis was set up, which would seem, at the post-mortem examination, to have been the only affection from which the patient had suffered. The question arose in his mind whether washing out the uterus under such circumstances would save the life of the patient.

The President thought that such cases would probably terminate fatally, whether the uterus were washed out or not; that it was then too late for treatment. His experience had been that the sooner the injections were begun in a case of puerperal fever the more successful would be the result.

Dr. G. G. Walker remarked that he had seen meto-perito- nitis treated by washing out the uterine cavity with the result of not reducing the temperature in the least. The diagnosis had been confirmed by a post-mortem examination.

Dr. Walker remarked that he had made use of uterine injections a great deal, both in private and in hospital practice, and had produced much benefit with them, especially in cases of threatening septicemia.

The President remarked that Dr. Jones published a case several years ago, in which the injections were begun after the temperature had reached 107° and 108°, and the patient recovered.

Dr. Walker remarked that he had published a case in which the temperature rose to 108°, and injections were continued for
six weeks before the patient finally recovered. He did not think we should always expect to find an external lesion which would account for the absorption of septic material; he believed that it took place more frequently from the inner surface.

The President referred to a case to which Dr. J. B. Hunter was called in consultation in a neighboring city about eleven days ago. The patient had been delivered five weeks previously, and was suffering from septicaemia with a temperature of 103° F., the pulse 120. Her family physician, who was a competent man, and several others had given up all hopes of saving the patient's life. When Dr. Hunter saw her he proposed to wash out the uterus, but was met with the most stubborn opposition. Obtaining the husband's consent, however, he proceeded to make the injections, and in less than twelve hours the temperature and the pulse fell, and the patient was greatly relieved. The treatment was still being continued. In reply to a question by Dr. McBurney, the President said the strength of the solution which he used at the present time was 2½ per cent.

Dr. Wheelock remarked that at the Nursery and Child's Hospital, when the temperature rose to 103° F., and there was a discharge of foul odor, uterine injections were used, and always with the most favorable results.

Dr. J. G. Curbis asked whether the cause of the entrance of air into the circulation in the cases which had been reported could in every case be traced directly to the introduction of the catheter into a uterine sinus.

Letters to the Editor.

ETHICS AT SANDY HOOK, CONN.

197 WEST FORTIETH STREET, NEW YORK CITY, July 6, 1883.

To the Editor of the New York Medical Journal:

Sir: In your issue of June 30, 1883, is a note from "Old-Code Man," with copy or slip from the "Newtown Bee" of June 22d.

As I am the doctor to whom this slip and your correspondent allude, I crave the opportunity to say that this note—for such it has the appearance of being—was entirely unknown to and unnoticed by me, and I read it for the first time in your journal, although I returned from Sandy Hook late upon the evening of the 1st inst., where I had been spending a few days with my friend Dr. Smith, to get breath of country air and to perform an operation upon one of his patients. I was not aware that my advertisement had been thus heralded, and heartily regret its unprofessional appearance.

I am a strong believer in the fact that "good wine needs no bush," and have always been careful that no bush should ornament my door, and, from a long acquaintance with Dr. Smith, I am sure his views are equally as strong on this point as are mine, and I am confident that this matter crept into the columns of the "Bee" more as a subject of local news than by reason of any desire to herald my coming.

The ridiculousness of your correspondent's connecting this matter with the "New Code" is very apparent, and partakes largely of the nature of Sergeant Buzfuz's "Chops and Tomato Sauce."

I have the honor to be, sir, yours respectfully,

J. OSCOTT TANSLEY, M.D.

SANDY HOOK, CONN., July 9, 1883.

To the Editor of the New York Medical Journal:

Sir: In notice in your journal issued June 30th a comment, signed "Old-Code Man," upon an item printed in the "Newtown Bee." I would not notice the article did it not implicate my friend Dr. Tansley, but for his sake I trust you will allow me space to show his true position in the matter. During last year I invited Dr. Tansley to visit me, and while here I asked him to operate on a few of my patients who required special treatment, but who could not afford or who had not the disposition to visit the city to consult a specialist or confine themselves in a hospital for a stated time. His results were so satisfactory that, after his departure, I was asked as a favor to inform several parties when he would repeat his visit. I sent for him a few weeks ago to operate for me, and obtained his consent to come. Meeting the editor of the "Newtown Bee" shortly after, I told him of Dr. Tansley's intended visit, and asked him to note the fact in his paper, as I had been requested to notify a number of persons who desired to see him. Two of them lived out of town and were subscribers to the "Bee." The result was the item in question.

To the Editor of the New York Medical Journal:

Sir: In reference to the item regarding Dr. Tansley, of New York, which recently appeared in the "Newtown Bee," and on which your correspondent commented, I would say that Dr. Tansley knew nothing whatever of its insertion, and it was printed after a conversation between Dr. Smith and myself, in which Dr. Tansley's intended visit was referred to. There was no idea of making an advertisement of it, as it was not paid for; it was given as a matter of news to several interested in the doctor's visit.

Respectfully,

R. H. SMITH,

Publisher "Bee."

ETHICS IN VERMONT.

NEW YORK, June 30, 1883.

To the Editor of the New York Medical Journal:

Sir: The pinnacle upon which some of the State medical societies perch in the matter of the "Code Question," and from which every visitor with lofty disdain certain other societies, does not, in some instances, seem to be composed of the solid material which such structures ought to contain. Acts which they so loudly decry in others they permit in their very midst, and even wink at more gross violations of the code, thus straining at the gnats and swallowing the camel—bump and all. If my recollection serves me, the Vermont State Medical Society refused recognition to the delegates of the New York State Society, and in its action proclaimed itself an adherent to the Old Code, which (though no more stringent than the "New") forbids advertising of specialties or remedies.

In glancing over a paper published in that State, I was somewhat surprised to find over the name of one of the members of the Vermont State Medical Society an advertisement of a "Remedy" which gave not only "Relief," but offered "A possible cure" for a certain disease. And, not content with affixing the title "M. E.," the advertiser made use of the "Dr.," making it read "Dr. ——— M. D."

Perhaps the Vermont society takes advantage of that "mental reservation" which, in its assumed adherence to the national code, it may think itself entitled to make use of.

THE PREVENTION OF CONCEPTION.

AUSTIN, Texas, July 5, 1883.

To the Editor of the New York Medical Journal:

Sir: On page 715, vol. xxxvii, of the journal we are told what a terribly wicked thing it is to prevent conception, etc. Then, again, on
MISCELLANY.

page 728, we are told that a certain unfortunate woman became preg

ant again, "although warned of the danger," etc. Now, is there not a

plague of insincerity in these two statements? What could have

been stated or implied to say "an unfortunate woman"? What course

indeed, should she have pursued? We are not told how the warn

ing was worded. What do you usually tell women to do who you

should think be "warned" against again becoming pregnant?

Those and other germane questions should be answered, not merely
to myself, whom you may consider hypercritical, but to the public at
large. I frankly acknowledge that I am often at a loss as to what I
should tell those unfortunate women who need warning, or who apply
for advice for means to prevent too rapid childbirth. And that there
are many women who bear children more frequently than is for
the good of any and all the parties concerned, even the State itself, there
can be no successful denial. This being the case, what are doctors of
medicine to do? Should they continue to grope and grovel with the
ignorance-fostering priestcraft, as in the superstition-controlled past,
or should they lay aside these things, and exert themselves to devise
some practical solution of this warning problem? It will not now
avail us to endeavor to smear or evade this momentous question, for
it is one that is daily growing more clamorous for an intelligent hear-
ing. From time immemorial we have been "warned" that the dread
fully destructive practices of preventing conception, of abortion, and of
fericide would depopulate the earth. But, does not the history of the
past, covering any or all of its epochs, up to date, prove beyond doubt
the utter and entire fallacy of such warnings? Do you rec any danger
of there not being enough children born in this or any other country?
All history of the past goes to prove that laws that were intended to
effect, directly, the increase of births have been of no appreciable in-
fluence in promoting an increase of the number of children born in any
given country. The increase in the number of children born is not
directly subject to the influence of legislative enactments.

This subject is too vast and momentous to be treated of in a letter but
yet certainly behoves those who have the talent and opportunity to
enlighten the public, to give them something better than the baseless
homilies and anathemas that have from time immemorial been set be-
fore the public.

With respect and best wishes,
I remain yours fraternally,
Q. C. Smith.

Miscellany.

THE ANNUAL MEETING OF THE STATE BOARD OF HEALTH OF WEST VIRGINIA.—We are indebted to a member of the board for the follow-

ing account of the annual meeting:

The State Board of Health convened at Martinsburg, Wednesday, the 11th inst., in annual session. There were present at this meeting the follow-

ing members of the board: Dr. George B. Moffett, President, of Parkersburg; Dr. Lawrence Curt, of Charleston; Dr. George H. Carpenter, of Morgantown; Dr. C. T. Richardson, of Charleston; Dr. James F. Reeves, the Secretary, of Wheeling; and Dr. William M. Late, of Bridgeport.

The secretaries read the minutes of the previous meeting, which were

approved, and then followed his report of the business of his office dur-

ing the preceding six mouths. Copies of correspondence with R. A. Harrison, Esq., of Columbus, O., were read, and the action of the secre-
tary in relation thereto was fully indorsed. The visitation of small-

pox in the counties of Mercer, Monongah, and Wyoming was next re-

ferred to, and the action of the local health boards in those counties in

successfully stamping out the disease was shown to have been one of

the good results to the whole people of West Virginia of the passage

of the State Board of Health law. It seemed evident that, but for

the specific powers granted under the law, and its energetic administra-

tion both by the officers of the State and county boards of health, the

whole southern portion of the State would have been swept by small-
pox from the starting point in Mercer, at a cost both of life and prop-

erty which would have been impossible to estimate correctly. From

the office of the secretary of the State Board the fullest instructions

were sent to the local health officers in the sequestered district for the

successful fight against the small-pox, all of which received the com-

mendation of the State Board. The importance of the case was of great importance in reference to the establishment of local county boards of

health. Under the law of 1881 the manner of their creation was

first, the nomination of three persons for each county by the State

Board of Health. These nominations so made were either approved or

rejected by the county courts. Now, under the amended act of

1882, the manner of establishing county boards was exactly reversed:

the county courts nominated and the State Board confirmed or re

jected, as its wishes directed. The term of office (two years) of the pre-

sent county boards would expire with this month, and it would be in order

for county courts to make their nominations for such officers to the

State Board. That due notice might be given, Dr. Reeves, the secre-

tary, was instructed to bring the matter, by circular letter, to the at-

tention of the counties, and at the same time urge upon physicians full

compliance with the law in relation to the duty with which they were

charged of promptly reporting to presiding officers of county boards all

cases of acute contagious and infectious diseases under treatment.

Four applicants for medical certificates presented themselves for

evaluation, of which number Dr. Hoffman, of Keyser, was the only

gentleman whose examination warranted the granting of authority to

engage in the practice of medicine and surgery in West Virginia.

The nomination of the State Board of standing of several medical colleges was next considered, and to the list of medical schools whose diplomas the board had already refused to recognize was added the American Medical College, of St. Louis, Mo.

Our correspondent adds:

"In the board's proceedings you will find that we have pronounced against another diploma until—the American Medical College (cf. New York, and that his headquarters are at 162 Broadway)"

The man hailed, referred to, is the one whose experience in West Virginia we alluded to in our issue of June 30th, p. 716.

pagel's DISEASE OF THE NIPPLE.—Dr. Louis A. Dubbing reports, in the July number of the "American Journal of the Medical Sciences," two cases of Pagel's disease of the nipple, which he holds is not an ec-

zema, but a peculiar disease with a malignant tendency. It must be dis-

tinguished from eczema, which it resembles, and from ordinary cancer,

which it is altogether unlike in its earlier stages. It seems to occupy

a ground having the characteristics of both diseases. The report is in-

teresting as showing the natural history of the affection. This is pe-

culiar. The course of the process is emphatically chronic. In both

instances, moreover, the progress of the disease was insidious as well as

low. Nothing of a malignant nature was suspected until after the

length of five and ten years, respectively. The itching, which eventually

became such a marked symptom, was in both cases insignificant until the

affection had existed several years. It may be said not to have

manifested itself until after the process had been well established. In

this respect the disease differs decidedly from eczema, where itching is

one of the first signs noted. The circumstances, sharply defined out-

line of the lesion, and the slightly elevated border, are also symptoms

which do not obtain in eczema. The brilliant color of the lesion is

striking, and is more marked than in eczema. The absence of the

"eczematous surface," characterized by appreciable discharge or by

vesicles, pustules, or puncata, coming and going from time to time, and

the absence of exacerbations, so usual in eczema, may also be referred to.

A point to which attention may also be directed is the infiltration,

which is firm or even hard, but is not deep-seated. It is rather super-

ficial. In eczema, on the other hand, it is soft. The pains coming

tater in the course of the disease, and the indurated, lumpy, or knotted

lesions within the gland structure of course strongly to the ma-
The Texas Sanitary Cordon of Last Summer.—In an exceedingly instructive article on The Sanitary Control of Epidemic Diseases, contributed by the Surgeon General of the Marine-Hospital Service, Dr. John B. Hamilton, to "Appleton's Annual Cyclopaedia" for 1882, we find the following graphic account of the cordon established in Texas last summer:

"A serious epidemic of yellow fever broke out in Bagdad, Tampico, and Matamoros, Mexico, and soon spread to Brownsville, in the State of Texas. There were in a short time, out of a city of some 5,000 inhabitants, between five and six hundred persons sick of yellow fever. A general panic prevailed throughout southwestern Texas, and refugees were leaving that part of the State in great numbers, as it was believed the infection would spread rapidly and certainly extend to the surrounding country. In these circumstances, an appropriation of $100,000 having been placed at the disposal of the Treasury Department by the President, to prevent the spread of epidemics, the Governor of the State of Texas applied to the Secretary of the Treasury for assistance from the general Government; and, as the exact area of the infected region was undetermined, at my suggestion a cordon was immediately established from Corpus Christi, on the Gulf, to Laredo, on the Rio Grande, along the line of the Texas and Mexican Railway. No person was allowed to pass this cordon until after ten days' detention at some one of the quarantine stations (represented by flags upon the accompanying map), that length of time being considered necessary to determine whether or not the particular person would be attacked with yellow fever. Baggage was not allowed to cross the line upon any pretext. A hospital was established in the city of Brownsville, a dispensary opened, and experienced physicians and nurses sent there, who were constantly employed in the treatment of the poor, and all persons unable to pay were treated and cared for at the public expense. The physicians also aided the health authorities of the city in carrying out sanitary measures, including the fumigation of houses.

"As soon as practicable after opening the hospital, an inner protection cordon was established, thirty miles from Brownsville, the original cordon having been one hundred and eighty miles distant. Perfect liberty was allowed to the inhabitants of the infected city to leave at any time, and they were encouraged to scatter in camps; but they were not allowed to cross the cordon until after personal detention of ten days, and fumigation of their wearing-apparel; and, as in the case of the outer cordon, the crossing of baggage was positively interdicted. It was intended to remove the upper cordon between Laredo and Corpus Christi within ten days after the formation of the inner one, which extended from Santa Maria, on the Rio Grande, to the mouth of the Sal Colorado; but it was retained for several days longer, as certain of the refugees who had left Brownsville prior to the establishment of the Colorado cordon developed yellow fever. They were quarantined in the camps where they were, and their infected bedding and baggage burned. The fever continued its spread and devastation on the Mexican side of the Rio Grande, and Reynosa, Camargo, Mier, and Guerrero successively became infected. It was then found necessary to protect the entire line of the Rio Grande, from Laredo to Santa Maria, a distance of nearly five hundred miles, by a cordon. The upper cordon, from Laredo to Corpus Christi, was then removed, and the line re-established along the Rio Grande, and the crossing-places carefully guarded; and, although the towns in Mexico were greatly devastated by the disease, there was no extension of it in Texas: on the contrary, it was confined to the isolated district where it first appeared, bounded by the Colorado cordon on the one hand and the Gulf of Mexico upon the other. The Mexicans, seeing the good effects of the sanitary cordon in the United States, followed the example, and established quarantine stations in Mexico, guarding against the infected towns; and there, too, the quarantine proved successful, and arrested the spread of the disease. The Governor, the State Health Officer, and the State officers generally, assisted the work of the Government by all the means at their command. It was, however, opposed by the mayor of the city. In July, a few cases of yellow fever appeared in Pensacola, Fla., and later the disease became epidemic, and, in Texas,
due to the absence of a sufficient quantity of hippuric acid to decom-
pose it; since, in proportion as the diet partakes of a vegetable, and
more particularly of a cerelal character, the amount of hippuric acid
in the urine is increased, and that of uric acid decreased. The quantity
of hippurate of sodium necessary, in a dilute solution, to decompose
uric acid to hippuric in the proportion of twenty-five parts to one.
Similar results were obtained by the use of benzoate of sodium, the
benzolic acid uniting with glyccin, or gelatin sugar in the body, to form
hippuric acid. As the chalk stones of gout and gravel or calculi con-
sist of urates of sodium, Dr. Garrod theoretically concluded that hippuric
of sodium would be useful in such complaints, and, putting the theory
to the test in clinical practice, he found that great advantage
was derived by patients from the use of the hippurate and benzoate of
sodium in cases of gout; so much so that patients asked to be allowed to
continue the use of the remedy.

Therapeutic Uses.—Hippurate of sodium acts advantageously on the
mucous membrane of the bladder and its appendages, and where there
is a tendency in the urine to become ammonical it is useful in check-
ing it, urine containing hippuric acid being less liable to undergo de-
composition than urine in which it is wanting. This healthy action on the
mucous membrane probably influences beneficially the secretion of the
coliold matter, and may thus prove valuable in cases of gravel and cal-
culus, since in these complaints the secretion of colloid matter is uni-
mately connected with the formation of the deposit of urates. The salt
is also likely to prove of service in some forms of eczema, which are
closely connected with the presence of uric acid in the blood.

Pharmacology.—Hippurate of sodium can be prepared artificially by heating
glycin with benzolic acid, but is obtained most easily by evaporating
the fresh urine of cows or horses to about one quarter its volume, and
then acidulating it with hydrochloric acid. The crude acid is then dis-
solved in dilute solution of sodium hydrate, the boiling solution freed
from color by the addition of sodium hypochlorite, and the hippuric
acid precipitated by hydrochloric acid, recrystallized from water, and
saturated with carbonate of sodium; or it may be obtained by boiling
the fresh urine of herbivora, with milk of lime, straining and evaporat-
ing, adding carbonate of sodium, and subsequently purifying the salt by
crystallization. The daily dose of the salt is twenty or thirty grains three
times a day.—

MISCELLANY.

THE INFLUENCE OF THE LYMPHATIC GLAND IN THE CEREBRAL CANAL
OF PHLEGMASIA ALBA DOLOM.—Mr. James T. Laffan writes to the
"Laurel" as follows: "The above-named gland, forming on either side
a most important link between the lymphatics of the trunk and lower
extremity, is the most dependent part of the lymphatics, and it is the
summit of the latter. It is admitted that phleghmasia alba doloma
is caused by the absorption of septic matter from the system by the
lymphatics of the pelvis. The germs thus absorbed set up inflam-
ination. Inflammation produces local hypertrophy. To the anatomist
it is evident that the lymphatic gland, occupying the innermost com-
partment of the sheath of the femoral vessels, is incapable of expan-
sion, so completely is it bound down and limited by the various struct-
ures in its immediate neighborhood in any direction save outward.
Externally it is almost in actual contact with the femoral vein, being
separated merely by the septum—a film of the transversalis fascia—
which practically offers no resistance. Inflammation having set in, the
enlarging gland presses upon the vein, bulging in its walls. A pro-
tection being thus forced into the cavity of the vessel, an eddy or
backwash in the current of blood is produced, and, consequent there
on, distintegration of the white corpuscles occurs, and phlebitis is set
up. The limb now, owing to venous obstruction, becomes edematous,
having the bluish color and pitting on pressure; the first familiar char-
acteristics of phleghmasia. Inflammation continuing, the stroma of the
the causes increases in density and choques up its afferent lymphatics.
Stasis of lymph occurs. The adena loses its merely venous charac-
ter, the limb becomes tense and hard, and will not sit on pressure—
second familiar characteristic. Pain is a marked feature in the initial
stage of this disease. In several cases under my observation, and in
the communicat experience of many practitioners consulted by me
on the subject, pAIN, deeply seated in the groin, has been the first
symptom complained of. This fact is, to a certain degree, in favor of
the theory of the pathology of phleghmasia now proposed. In the
whole system there is no other gland so situated that its enlargement
could produce a train of events similar to what I have described. If
any gentleman who has the opportunity of making a post-mortem ex-
amination of the body of a patient who suffered from phleghmasia would
direct his attention to an examination of this gland, the result might
confirm what at present is but a probability. The idea may be of
practical value in this way, that, if the disease, as it manifests itself,
be due to the tension of the fasciae surrounding the gland, a subcuta-
nous division of its anterior investments would give it room to expand
otherwise than directly to the femoral vein. Thus the phlebitis,
with its certain inconvenience and possible danger to life, would be
avoided."

THE TREATMENT OF SPINAL CURVATURE BY RECLINATION IN ITS
EARLY STAGES.—Mr. Edward Lund, F. R. C. S., writes to the "British
Medical Journal":

"I hope to exhibit, at the forthcoming meeting of the British
Medical Association at Liverpool, a form of couch for the treatment,
by reclination, of spinal curvature in its early stage, and weakness of
the muscles of the spine, which embodies in its action a principle of
treatment for such cases too frequently overlooked.

"The couch which I have to recommend, and which will be shown
at Liverpool, is designed to carry out by reclination the same principle
of treatment as operates in the method of vertical suspension, only in
a more gradual and prolonged manner. I have called my couch a
'slipping couch,' and I think the construction and mode of action will
justify the term. I have used it with marked benefit during the last
few years, in more than thirty cases, in private practice. It is made
in this way. A piece of wood is prepared, of suitable thickness,
and about six feet long and eighteen inches wide. At about four inches
from one end a hole is cut through the wood, of circular form and
six inches in diameter, with its margin on one surface of the wood
being bevelled inward. This end of the piece of wood is to be the
upper or higher part, when it is fixed at such an inclination by means
of a block or cross-piece as to raise it about one foot at the higher
end. It is well to have four wooden legs screwed on, at each cor-
ner, the upper pair being longer than the lower in the same propor-
tion; and to still further influence the angle at which the couch is to be
used, by means of extra screw-holes in the wood: the longer pair of
legs being brought nearer to the foot of the couch, a greater elevation
can be secured. The flat piece of wood, being so prepared, is covered
with several folds of soft, thick blanket to about two inches in thick-
ness, the blanket being just the size of the wood on one surface only;
over this a piece of well-polished black horse-hair cloth is stretched,
and, being turned tightly over the edges of the board, is nailed under-
neath, so as to produce a smooth, smooth, and yet slippery,
most polished surface. Where the blanket crosses over the hole
already described, it must be cut across in two directions, longitudinally
and transversely, and the horse-hair cloth should be let over these
same spot, so that, if pressure be here applied, an induration will be
quickly made.

"Now, if a couch be prepared in this way, and placed at such an
angle of elevation as I have here described, about one part in six
of its length, a person lying upon it on his back will soon find, unless
he make some effort to resist, that he will quietly slide down toward
the lower end of the couch; and, if his attention is otherwise ab-
sorbed, he will have his feet over the end of the board, as he is slip-
ning beyond it. By a very simple device, this tendency to slide or slip
downward may be very beneficially utilized for the object we have in
view.

"A small, firm, cylindrical pillow is prepared, about the diameter
of the wrist and a foot in length, and this is attached by strong tapes,
one at each end of the pillow, and fixed to each upper corner of the
wood. This curtain of tapes being such as to place the pillow trans-
versely on the board immediately below the lower edge of the hole
in the wood. With this pillow in position, and the patient so placed that
the pillow may be received into the reves of the nape of the neck,
the projection of the occiput falling into the depression made by the
hole in the wood, the body is retained in position, and the sliding down
July 21, 1883.

MISCELLANY.

is prevented, but yet there is a constant gentle draging action on the spinal joints from the weight of the pelvis and lower limbs, which will act most favorably in the required direction.

It is desirable, when a patient uses this couch for the first time, that he should try it without the pillow; and, if needful, the elevation of the couch should be adjusted until the peculiar sliding movement is experienced. Then, with the help of the pillow, and the back of the head falling into the recess prepared for it, the patient will be aware of the principle upon which the couch is intended to act, and be more likely to continue its use.

"All other couches, such as the Ilkeley couch, and couches with a double angular band to support the knees, or with a foot-plate against which the feet can rest, are entirely opposed to principle in the plan of this 'slippery couch.' Using them, the patient may feel rested, and experience some temporary relief; but I know of no way, by re-arrangement, to secure a certain degree of spinal extension better than to fix the upper segment of the vertebro-cranial axis at one spot, and allow the weight of the lower part to induce direct self-extension."

On Cystotomy by a Modified Lateral Method in Certain Cases of Enlarged Prostate.—In a recent number of the "British Medical Journal," Mr. Reginald Harrison, Surgeon to the Liverpool Royal Infirmary, says: "Within recent years I have had cases where it has been found expedient to make an opening into the bladder by the method of a lateral oper- cation, the usual views of alleviating obstruction by excision, or the consequences arising therefrom, having failed or proving insufficient. I may premise by stating that, apart from those cases of obstruction complicated with circumanurethral abscess, no such proceeding has been undertaken on the sole ground that catheterism was impossible, though some difficulty connected with the performance of the operation has, with other circumstances, usu- ally been present. The selection of a method for opening the bladder should have reference only to the object to be attained, or the contingencies that may arise. If, for instance, we desire merely to introduce the catheter, as a preliminary to extracting a small stone, the median operation answers perfectly; while, if a larger stone, or an un- known quantity of anything, has to be dealt with, the lateral incision will, as a rule, be preferable. It has been advanced by those who favor the median incision, which is practically a urethrotomy, that it is both simple and safe; its admitted disadvantage lies in the com- paratively small space it provides for manipulating and extracting; while, on the other hand, the lateral incision, though affording more room, is considered to be attended with an increased risk and a greater degree of difficulty, so far as its performance is concerned. The me- dian operation need not necessarily involve anything more than the opening of the membranous urethra; the completed lateral opera- tion further includes the division of structures constituting the neck of the bladder; and it is to this part of the proceeding that any in- creased risk or difficulty is to be attached. A little reflection shows that it is possible to closely assimilate the lateral with the median operation; that is to say, to dispense with the incision, not to the staff, but along the staff, should it be found, on exploration with the finger, that the additional room which the latter part provides is unnecessary for the object in view. It need hardly be said that this modification of the lateral method, where it is found, on digital exploration, to be feasible, frees the operator from executing the only portion of the operation to which any increased risk is attached; while, on the other hand, he has the consciousness that, should it turn out to be necessary, he can, by the completion of the deep incision along the staff, avail himself of all the advantages which are conceded by surgeons to the lateral method of opening the bladder." Mr. Harrison illustrates his method by the description of a case.

Cannabis Indica; a Valuable Remedy in Menorrhagia.—"Indian hemp," says Mr. J. Brown, of Barcram ("British Medical Journal"), has been vaunted as an anodyne and hypnotic, having the good qualities of opium without its evils. Also in dysmenorrhoea and leucorrhea it has proved of much benefit. The drug has almost invariably produced some marked physiological effect, even in small doses. Text-books give the dose as ten minims and upward, but five minims is the largest dose that should be given at first. If bought from a good house, the drug is not inert or unreliable. A drug having such marked physiological action ought to have a specific use as a therapeutic agent. Indian hemp has such specific use in menorrhagia—there is no medicine which has been such good results; for this reason, it ought to be put into the first place as a remedy in menorrhagia, then bromide of potassium and other drugs. The modus operandi I can not explain, unless it be that it diverts a larger proportion of blood to the brain, and lessens the muscular force of the heart. A few doses are sufficient; the following is the prescription: B. tincture cannabis indica, x xxx; polvis tragac. co. 3 j; spiritus chlorof. 5 j; aquam ad 3 j. One ounce every three hours."

Dr. Robert Batho, of Castletown, Isle of Man, writes in the same journal: "Considerable experience of its employment in menorrhagia, more especially in India, has convinced me that it is, in that country at all events, one of the most reliable means at our disposal. I feel in- clined to go further, and state that it is par excellence the remedy for that condition, which, unfortunately, is very frequent in India. I have ordered it, not once, but repeatedly, in such cases, and always with satisfactory results. The form used has been the tincture, and the dose ten to twenty minims, repeated once or twice in the twenty-four hours. It is so certain in its power of controlling menorrhagia that it is a valuable aid to diagnosis in cases where it is uncertain whether an early abortion may or may not have occurred. Over the menorrhagia attendant on that latter condition it appears to exercise but little force. I can recall one case in my practice in India where my patient had bled profusely at each period for years until the tincture was ordered; there- upon, by commencing its use, as a matter of routine, at the commencement of each flow, the amount was reduced to the ordinary limits, with corresponding benefit to the general health. Neither in this, nor in any other instance in which I prescribed the drug, were any disagreeable physiological effects observed."

Floating Kidney.—At the meeting of the Glasgow and West of Scotland Branch of the British Medical Association, held June 29, 1883, Dr. Newman gave a short account of four cases of movable kidney, one in a male and three in females. In one of these cases he performed the operation of nephrotripsy with very satisfactory results. Previous to the operation the patient suffered severe renal pain on the right side, associated with persistent nausea and vomiting, so that she had not been out of bed for full two years. After the operation the symptoms disappeared, she was able to take a consider- able quantity of food, her general health had greatly improved, and she could now take moderate out-door exercise. In another case the patient suffered from the same symptoms as the one above described, and, in addition, symptoms referable to strangulation of the right ure- ter, and persistent albuminuria. The urine contained a small quantity of albumin and granular and hyaline tube casts. While the patient was under observation, the right kidney diminished considerably in size, so that the question was raised whether or not the albuminuria was due to disease of the movable kidney alone. The only method of determining this with accuracy seemed to be to procure separate samples of urine from each kidney. This was done by introducing a small electric light into the bladder along with a speculum. The cri- fis of the ureters were thus easily seen, and, two catheters being introduced, one into each ureter, the urine was allowed to flow into separate vessels, and afterward examined chemically and microscopi- cally. The result of this examination was to show that both kidneys were in a diseased state, and therefore an operation was not considered advisable. Both the cases described were in females.—Glasgow Med. Jour.

Removal of the Thyroid Gland.—At a recent meeting of the Surgical Section of the Academy of Medicine in Ireland ("Dublin Journal of Medical Science") Mr. Thosney Stocker read a paper on removal of the thyroid gland in cases of bronchocoele. He detailed attending the case of a boy on whom he had been operated, the disease being the most extensive of which he could find any operative record. The tumor extended nearly from ear to ear, and lung down nearly as low as the naval. He removed two thirds of the mass, comprising the right lobe and isthmus, in March, 1882, and the remainder on the left
side a year later. Complete recovery followed the first operation, but the patient died five days subsequent to the second from pulmonary thrombosis. The patient was incompletely treated, but developed greatly after the first operation. Mr. Stoker showed that while ten or twelve years ago the ablation of the thyroid gland for disease had been practically abandoned, during the last decade a revolution of surgical feeling on the subject had occurred, and that now it should be held justifiable, as the result of late experience, to perform the operation, the patient so desiring, not only in cases where the disease threatened life, but where discomfort or disfigurement existed and minor treatment had failed. He emphasized his argument by quoting a series of cases from the practice of various surgeons, commencing in 1871 with the late Dr. William Warren Greene, of Portland, Me., whom he regarded as the pioneer of the most modern opinion on the subject. The freedom with which the operation had of late been undertaken was, he thought, in part due to the results of Listerism, and in part to the greater boldness which increased knowledge and improved appliances had generated in the surgeons of our day.

The Therapeutic Value of Nerve-Stretching in Tabes dorsalis.—Mr. Stokes read a paper at a recent meeting of the Medical Section of the Academy of Medicine in Ireland ("Dublin Journal of Medical Science"), in which he commenced by pointing out that the evidence afforded by the cases of tabes dorsalis treated by nerve-stretching indicated the fact that relief from some of the most distressing symptoms of that disease might, if the operation be performed sufficiently early, be anticipated. He considered that the absence of a physiological explanation as to how the operation acted was no reason for its rejection, and gave instances of other operative procedures of which the modus operandi was as yet unexplained. He particulars of two well-marked examples of the disease treated by him—in one of which he stretched the sciatic nerve on one side, and in the other on both sides—were then given. Although the operations were not followed by any signal improvement in motor power, the results in other respects, as regarded relief from lightning pains, vesical irritability, and return of sensibility in certain regions of anesthesia, were satisfactory and encouraging. The views of various writers on the effects of stretching on the nerves were discussed, and those of Cecherelli shows to be at variance with the results obtained in the author's cases, and also with the experience of Dr. Brown-Sequard. Then Mr. Stokes discussed the importance of estimating accurately the amount of force that should be used, and was of opinion that a very moderate amount was sufficient to obtain the desired therapeutic results. He also stated his belief that many of the recorded failures of the operation were to be attributed to the employment by the surgeon of an undue amount of force. He advocated the use of an electric cord and dynamometer in nerve-stretching, and believed that in the case of the larger nerves a force of about ten pounds would be found sufficient. Although a satisfactory physiological explanation as to how nerve-stretching produced the results observed was still to be obtained, we were not wholly in the dark. He quoted Dr. Brown-Sequard and Dr. Charlton Bastian to show that after the operation a certain amount of vasal-paralysis was produced, resulting in vasoconstriction and increased temperature of the part, and that the improvement which occasionally followed the operation was probably connected with these phenomena.

A Remarkable Mostrosty.—Dr. Mulryan ("British Medical Journal") describes the case of a príádpárí, aged twenty-eight, who had been some hours in labor. It was a breech presentation, and favorable progress had been made until the pelvic outlet was reached. There the head became jammed tightly, and during the next two hours did not advance in the smallest degree. As the pains were easing, notwithstanding the administration of ergot, it became necessary to deliver the woman forcibly. Several attempts at extraction by forceps proved futile, and, as exhaustion was threatened, the blunt hook was employed, and, after an hour's hard work, delivery was accomplished. The child was a full grown anæmolæbal male; life was extinct but very recently. The bones of the face were normally developed, but there was no calvaria. The cerebral substance was wanting, and its place was filled with bloody serum and a material which looked like a placenta; to this the placenta proper was attached by its membrane. It was very large, measuring 94 inches by 94 inches, and was deeply fissured at its anterior third. Two abortive cerebellar lobes were present. At the upper portion of the spine there was an opening into the spinal canal, from which sprang a lobulated body. Four cords were present, three focusing at this point; one running from the placental cerebral substance, the other from the placenta, and the third joining the cord proper, a few inches from the umbilicus; the fourth passed from the placenta in the usual way, and presented a slight degree of fatty degeneration. It was rather large. The other cords had undergone fatty degeneration to a great extent.

The Bacillus of Tuberculosis in an Abscess near the Anus.—Dr. Robert C. Smith writes in the "British Medical Journal": Six months ago a young clerk, aged twenty-one, came under treatment for hemoptysis and other signs of phthisis. About three months' treatment he became strong enough to resume his employment, at which he continued up to the commencement of this month. I saw him on the 6th, when he was suffering acutely from an abscess in the neighborhood of the anus; and, fearing lest it might burst into the bowel and give rise to a painful blind internal fistula, I opened the abscess at once and let out a quantity of thin, cloudy, fist ulous pus. A microscopical examination of this fluid by a half-inch object-glass, after the usual process of staining, revealed the presence of great quantities of well-marked typical tubercle-bacilli. Now, the presence of these organisms in this situation is interesting, as they tend to throw some light on the well-known connection between fistula and phthisis.

A New Mode of Burial.—At the recent general assembly of cement manufacturers at Berlin, says the "Lancet," Dr. Fröhling described a new application of cement. He explained that it would be easy to transform corpses into stone mummies by the use of Portland cement, that substance, when hardened, not in any way indicating the organic changes going on within it. He further illustrated the subject by describing various industrial uses of lime as a preventative of decomposition. The cement in hardening takes an accurate cast of the features which it incloses, thus allowing of their exact reproduction after the lapse of centuries. It is suggested to use coffins of rectangular shape, it being further considered by Dr. Fröhling that underground sepulture is needless, as the coffin soon become practically masses of stone, and can therefore be built into pyramids.

Army Intelligence.—Official List of Changes of Officers of the Medical Department, United States Army, from July 7, 1883, to July 11, 1883.—Bailey, E. I., Colonel and Surgeon. In addition to his present duties, to take charge of the office of Medical Director, Military Division of the Pacific, during the absence of the Medical Director.

Sutherland, C., Colonel and Surgeon, Medical Director Military Division of the Pacific. Granted leave of absence for one month, with permission to apply to the Adjutant-General of the army for extension of two months. Par. 1, S. O. 64, Military Division of the Pacific, June 30, 1883.—Campbell, J., Assistant-Colonel and Surgeon, Medical Director Department of the South. Leave of absence on surgeon's certificate of disability granted by S. O. 60, Department of the South, May 21, 1883. Extended one month on surgeon's certificate of disability, with permission to leave the Department of the South. Par. 7, S. O. 156, A. G. O., July 9, 1883.—Perley, H., Assistant and Assistant Surgeon. Assigned to duty at Fort Pembina, D. T. Par. 1, S. O. 118, Department of Dakota, July 5, 1883.

Navy Intelligence.—Official List of Changes in the Medical Corps of the Navy for the week ending July 14, 1883.—Medical Inspector A. Hudson, Assistant to Bureau of Medicine and Surgery, and Passed Assistant Surgeons S. H. Griffith and E. H. Green, granted leave of absence for one month.

Society Meetings for the Coming Week.—Tuesday, July 20th: Medical Society of the County of Kings, N. Y.; Medical Society of the County of Otsego, N. Y. (Cooperstown—annual); Ogdensburg (N. Y.) Medical Association. Wednesday, July 21st: New Jersey Academy of Medicine (Newark).

THE ESSENTIAL NATURE OF
DIABETES MELLITUS VULGARIS.
By F. EKLUND, M. D.,
STOCKHOLM, SWEDEN.

By the most meritorious experimental researches, executed especially in the last decennium for the purpose of investigating the true causes of diabetes mellitus, by exact clinical observations and scrupulous examinations of the alterations of nutrition in diabetics, a great many valuable facts, like the refracted beams of a prism, have been gathered, but, nevertheless, we must even to-day complain, with Saltkowski and Leube,* that the disease in question is indeed a dark enigma. After giving some concise citations,† I will, however, try to show that it is possible, by reassembling some refracted beams, to gain a solid point of issue in order to suggest a theory in most respects satisfactory as to the essential nature of common diabetes mellitus.

This theory I will essay to support by my own experience of the disease in question, by microscopical examinations of the urine and the other excretions, by analogies collected from pathological histology, vegetable physiology, and special animal parasitology, by an exposition in a few theses of the properties of the yeast-cell as shown by my own unassuming but exact experimental researches.

Furke‡ says that diabetes arises spontaneously in men in consequence of pathological conditions which are unknown still to-day. It is evident that these mysterious causes may be arranged under the two categories: local circumstances, and personal faults (Parkes). Yet, before pursuing the development of the matter in this direction, I will state that the urine of diabetics, quite fresh, gathered with all necessary precautions not to be deceived, contains yeast-cells as a rule that, I believe, are indeed excreted from the kidneys in the same manner as all the other vegetable miasmas; for example, the Torula morbillorum, the Plaz scindens, the Micrococcus ptthiosis irritans, the Limnaphysalis hyalina, and so on, while, on the contrary, not one yeast-cell is present in the faces of the diabetic. Thence I regard myself authorized to infer that yeast-cells are constantly to be found in the circulating blood, and constitute integral parts of some, or of the most, or perhaps of all the organs of the body in diabetics. These yeast-cells are identical with the Saccharomyces minor, ellipsoideus (and apiculatus).

As to how the yeast-cells may have entered into the innermost parts of the body—for example, the liver—the experience of Senator* and my own teachings that disorders of digestion play an important part in many cases. Cornil and Ranvier|| tell us that during acute catarrhal gastritis the epithelium of the stomach is completely detached, and that the superficial network of capillaries shows a very notable distension. It is indisputable that these pathological states, considering, moreover, the considerable accommodative facility of the yeast-cell and its buds, are local accidents of high importance for the entrance of the yeast-cells into the blood-vessels of the stomach, and, further, into the system of the vena portae. In an analogous manner the infectious diseases—as ague, measles, scarlet fever, and so on, which produce, besides, a universal debility of the organism—prepare the way for the yeast-cells to grow into the stomach as a miasma. That this peeling off of the epithelial cells, just now mentioned, facilitates the penetration of such extremely minute particles as germs, etc., pemphigus of the mucous membrane of the stomach gives us an example. In the cellular texture, after the superficial ulcerations, Chalvet* has observed deposits of subminate of bismuth, which were formed there during the period of activity of the ulcers.

A striking analogy among the vegetables is afforded by ripe cherries, whose outside is found everywhere overspread with yeast-cells by thousands. It is not until the cherries begin to wither and grow musty that the buds of the yeast-cells can penetrate the weakened cuticle and produce fermentation.

By the by, I will remark here that, if during the above-mentioned diseases yeast-cells are observed in the urine, this signifies that the patient is in great danger of becoming diabetic, if he can not eliminate the yeast-cells as he recovers. The destruction of these can even be effected by aponea if they, in their struggle for existence, lose the power to appropriate to themselves the haemoglobin of the red blood-cells loosely combined with oxygen. Upon an average, the living plasma and tissues, on the setting free of the oxygen from the red blood-corpuscles, have a much greater affinity for the oxygen than the yeast-cells, which explains the great difficulty for the latter to bud and multiply in the living body. On the other hand, the very often almost unavoidable fatal consequences for the human body of the nestling down of the yeast-cells in the liver, where they not only partly prevent the dehydration of grape-sugar into glycogen, probably even by hastening the blood circulation, but also and especially change the liver-glycogen to grape-sugar, and their spreading from the liver with the circulating blood to the other parts of the body, are chiefly dependent on the property of their protoplasm to act as an analytical or hydratative ferment on the liver-glycogen, formed itself, as well as the fat, by an analytical process, consisting in decomposition of protoplasmatic matters,† whereof the hæmoglobin in the blood of the liver probably constitutes the mother substance,‡ from which the glycogen, the urea, and the coloring matters of the bile are derived,§ as by synthesis of grape-sugar.

* Cornil et Ranvier, op. cit., p. 287.
† Senator, op. cit., S. 476.
§ Possibly this increased annihilation of haemoglobin explains the diminution of oxygen appropriated during diabetes (von Wittich, op. cit., loc. cit.).
In an analogous manner we see in the vegetables—for example, in unripe peas—the dissolved albuminoid matters, resembling the cerealin of gluten, produce the hydration of the starch to sugar, and this effect cease simultaneously with the hardening of the albuminates, when the sugar is dehydrated again to starch. On the liver-glycogen the yeast-cells exercise their influence so much easier by reason of the abundance of dissolved albuminates and their derivatives, which deliver an almost unconsumerable material for the production of a diastatic ferment, that is formed by means of end- and exosotic exchanges through the cellular membrane of the saccharomyces, simultaneously with which the dissolved albuminates facilitate the access of the ferment of the yeast-cells to the glycogen by the softening of the envelop of the glycogenous sacs.

Yet to-day much obscurity prevails on the essential nature and the mode of action of the protoplasm and the brilliant corpusules on the germes of the yeast-cells, and divergent opinions contest with each other as eagerly as at any time to gain the superiority. Under such circumstances, I will, in order to support my theory, only allege the following, by approved authorities, as valid, confessed scientific truths and facts:

1. For the transformation of starch and of cane-sugar into grape-sugar within the vegetable and the animal organism the active substance is a soluble ferment; that is, secreted from the yeast-cell and identical with that which is present in the small intestine of animals, where it plays an analogous part.

2. The pancreatic diastase possesses the faculty of metamorphosing to sugar and to dextrin as much as forty thousand times its own weight of starch.

3. The morphological ferment has a higher organization, and operate, according to unanimous opinion, more speedily and regularly than the amorphous. Consequently, to convert 40 grm. of starch to sugar, rather less than 0.001 grm. of yeast-cells is sufficient; to change 50 grm. of starch, less than 0.00125 grm. of yeast-cells is enough, and so on.

4. It is only when not growing that the yeast-cells effects fermentation, because the yeast-cells are active ferment only when deprived of free oxygen and obtaining as azotic nourishment albuminoid matters—that is to say, the products of metamorphosis and disintegration of these last mentioned, inasmuch as the easily soluble and diffusible derivatives of the albuminates (for example, the peptones, diastase, and syntonin, finally even allantoin, urea, uric acid, and guanin) constitute perfectly appropriate aliments for the yeast-cells.

5. Sometimes repeated access of free oxygen is in some measure a capital condition for the renewal of the life of the yeast-cell, which otherwise would die.

6. Fermentation represents in no wise a simple process of vegetation and alimination of the yeast-cell, but it may, under some circumstances, show opposite states of things—viz., form much yeast and hydrate little glycogen, or form little yeast and hydrate much glycogen.

7. If to a mixture of yeast, water, and common starch, which is unboiled and its cells consequently uninjured, we add a very little of an infusion of any grain whatever, prepared with cold water, we shall find that in this infusion the soluble albuminoids undergo the action of the yeast, and are decomposed from their composite molecular structure to the condition of a less complex molecule. In other words, they are less colloid and gummy; they are more unstable. This particular molecular modification is the result of the influence exerted upon them by the yeast; so altered, these albuminoids gain the faculty of penetrating the wall of the starch-cell, and thereby effecting the hydration of the starch. The sugar is produced by the intervention of the soluble albuminoids in wheaten meal. From this, one is authorized to infer that the yeast-cell alone is impotent to penetrate as far as to the starch in the cell, and that the effect produced by the yeast is only indirect. This action consists, above all, in the change of the form of the soluble albuminoids, and ultimately in facilitating their penetration through the walls of the starch-cell.

8. If we inquire why the sugar in the blood proceeds no further in fermentation—viz., to alcohol—Thudichum answers: Because the blood serum shows an alkaline reaction. The yeast itself is always acid.

9. The most favorable temperature for the fermentative process is +25° C. to +30° C.; but, according to Marchand, the temperature at which most protoplasm unfold their maximum of activity varies between +35° C. and +40° C.

10. Saccharomyces does not lose its vitality at -113° C., nor at +130° C.

11. According to Ehrenberg, a single microbe can produce one million of the same sort in a day, and in four days one hundred and forty billions, which represent almost two cubic inches.

12. The yeast-cells destroy the best aliments, and products arise that contain a smaller quantity of potential energy. The yeast-cells possess at the same time a synthetical and an analytical faculty. In the former case they compose the proteic matters of sugar and ammoina proper for their nutrition; in the latter case they influence the soluble albuminoids to form a less complicated molecule.

* Hiller, op. cit., p. 397.
† Ibid., p. 406.
13. The large group of ferment* consists of destroying, consuming cryptogams, which effect combustion of oxygen by their respiration. Whereas they are deprived of chlorophyll, and can not produce organic matter for themselves, they are forced to live at the cost of those which produce hydrates of carbon; wherever they find this combination they appropriate to themselves, producing disease of the organism in which they grow, devouring it little by little, and turning it into their own substance.

14. As an evidence† that the exposition given in the last paragraph possesses validity and application even to the saccharomyces, I will quote the following example as an analogy from the animal kingdom:

The sacculina, the parasite of the crab, is in its turn attacked by a parasitic disease that effects its atrophy and eventually its complete destruction. S. Jourdain has sometimes hit on these sacculina, in the last stages of pathological regression, measuring only 0'002 or 0'003 μ in diameter, which were distinguishable from the young of the same collection by the blackish furfuroaceous pigment with which they were covered then. The stomatization—that is, the root-formed prolongations, which proceed from the anterior pole of the genital sac of the sacculina careinii—appear to be filled up by a saccharomyces, which is sharply defined from the mycoderma viri and the saccharomyces cerevisia with which S. Jourdain has compared it. It buds and multiplies like the saccharomyces. Moreover, every one of the poles, which correspond with the longest axis of the cell, can emit a mycelium-shaped prolongation, that S. Jourdain has succeeded in following in its evolutive cycle.

All the cryptogenic cells that S. Jourdain has cultivated in the humid chamber in the midst of a saccharine fluid have emitted, without exception, this double prolongation, whose evolution requires possibly a change of the medium. Often these yeast-cells have appeared associated with porosperms of variable dimensions.

From these general considerations we are naturally led to answer the question concerning the occurrence of the saccharomyces minor and ellipsoides in the common substrata of material life. Microscopical examinations have brought to light that these are to be found in the drinking-water in Sweden in sundry places where diabetes is observed sporadically, together with greater or smaller colonies of a species of extraordinarily subtle bacilli, whose diameter is 0'3 μ, the length of each individual varying from 2 to 3, 4, 5 μ and more. They are articulated, and hang together in long rows. If it is to the action of this microbe that we must impute the production of acetone in diabetes, or if, together with the saccharomyces-cells, it contributes to hasten the decomposition of the albuminoid matters in diabetics, it is impossible to decide to-day. The local essential conditions are, of course, in some measure, quite the same as those which produce some other infectious diseases; as, for example, the ague, scarlet fever, and so on. The relative rarity of diabetes in comparison with the last-mentioned epidemic diseases might have its explanation in the great difficulties even for the growing yeast-cell to penetrate the normal mucous membrane of the stomach and of the intestines. In the faces I have, as a rule, in diabetes found no yeast-cells. In the cases in which no saccharomyces cells can be detected (by accident) in the urine, the protoplasmatic corpuscles (the brilliant germs) of these may be observed, surrounded by a little protoplasm. Under favorable circumstances, i., the presence of urea, oxygen, and sugar, the protoplasm is augmented, and the germs are enveloped with a membrane of cellulose.

The "personal faults" play a particularly important part in the production of diabetes. The principal and most frequent are errors in diet, as immoderate eating of amylaceous foods or saccharine fruits, with consequent disorders of the digestion and a faulty composition of the blood and of the other humors of the human body by the wrong direction of the whole nutrition and assimilation; abuse of spirits, by which the human organism is converted into an arid dough, where the yeast-cells act almost the same disastrous part as the spark of fire in the powder-room; further, want of bodily exercise, profoundly agitating emotions of the mind, and so on. In the very same places where, as for example in Ceylon and the Thuringian Forest, the local essential and the predisposing personal influences are more often combined—that is to say, where the inhabitants make an immoderate use of saccharine fruits, whose surface is covered with energetic yeast-cells (Saccharomyces apiculatus), diabetes is more frequent.

It is well known that the inulin of the artichokes of Jerusalem resembles glyceogen the nearest of all amylaceous matters. By digesting thin slices of such artichokes at a temperature of + 37° C., together with yeast-cells, their amount of sugar is considerably augmented in a few minutes. Under the same conditions the liver of fresh oysters, rich in glyceogen, shows a manifest reaction of grape-sugar.

The mild cases of diabetes are cured by means of an exclusively animal diet, much bodily exercise, alkalies, hydrotherapy and sol. iod. spirit.; ten minimis in sweetened water thrice to four times every day. The severe cases are all incurable, although we know that phosphorus and arsenic annul the glyceogenic function of the liver, and iodine and also many other substances (without the living organism) annihilate the fermentative faculty of the protoplasm of the yeast-cells.

APPENDIX, CONTAINING THE CHIEF THEORIES OF THE NATURE OF DIABETES MELLITUS.

1. The essential cause of diabetes is, according to Tunke,* the exceeding accumulation of grape-sugar in the blood; this accumulation, itself, again may arise in different manners. 1. It may be produced directly by injection of solutions of sugar into the blood; 2. It arises spontaneously in man during, for the present, unknown pathological conditions; 3. It appears as a consequence of some lesions of the nervous system; and 4. As the effect of the influence of some poisons on the nervous system. Lesion of the medulla oblongata at a definite spot in the floor of the

† L. L. Le Laressan, "Revue internationale des sciences biologiques," 15 juillet, 1881, pp. 82, 83.
fourth ventricle (at the apex of the calamus scriptorius), section of the spinal marrow at different heights, poisoning with curare, at the same time sustaining the blood circulation by means of artificial respiration, yet only with incomplete inflation of the lungs, effect diabetes (justly and properly * called a transitory mellituria). It is proved that in all these cases the sugar which is accumulated in the blood is liver-sugar. But from this it follows that the forms of diabetes mentioned depend either (1) on an increased metamorphosis of the already present liver-glycogen into sugar, or (2) on a lowering of the processes which normally annululate sugar, either in the blood or in the textures, so that their extinction must, of course, produce an accumulation of the said matter in the fluids of the body.

2. According to Claude Bernard,† the cause of diabetes is an increase sometimes of the whole function of the liver, sometimes only of the change of the glycogen present into sugar in consequence of an active congestion of the liver, depending on a paralysis of its vaso-motor nerves.

3. Schiff ‡ argues that a hyperemia produced by paralysis of the vaso-motor nerves in any considerable vascular area causes the formation of a ferment which is not to be found in the normal blood, but which within the liver changes the glycogen into sugar.

4. Pettenkofer and Veit * declare the cause of diabetes to be, that with a normal synthesis of glycogen in the liver the decomposition of the sugar produced is retarded or suppressed by impeded oxidation in the blood, but neither is the fundamental fact, the decomposition of the sugar, to be admitted, nor is the truth of the different hypotheses which are suggested to explain the causes of the pretended checking of the oxidation demonstrated.

5. Tscherinow, § who regards the liver as a sugar-destroying organ whose physiological object is the metamorphosis of sugar into glycogen, maintains the view that in diabetes the energy of the liver in the processes of oxidation (more properly, dehydratation 2) is impaired.

6. According to Pavv, ¶ the cause of diabetes in men is a paralytic dilatation of the vessels of the liver.

7. Trumet de Fontarce †‡ thinks that the genuine diabetes is of paralytic origin, depending on dilatation and hyperemia of the vessels of the liver in consequence of their privation of the contractile stimulation of the vaso-motor nerves. It is only a transitory glycosuria, certainly a pregnant symptom of diabetes mellitus, but never the real constitutional diabetes, that has been produced in an experimental way.

8. Senator ‡§ suggests that diabetes may arise: 1. From an abnormally augmented quantity of sugar in the chyle or in the blood of the vena porta, or in these two together.

This excess of sugar depends on an impeded metamorphosis into lactic acid of the sugar in the intestines, or on an accelerated resorption of the sugar. 2. The cause of diabetes is an abnormal acceleration of the circulation in the vein porta, whence generally more of the sugar ingested or derived from starch enters the liver. From this organ it is transported into the circulation, without having been metamorphosed into glycogen, but, moreover, the glycogen formed from sugar or other matters is transformed again more speedily and in more considerable quantities into sugar than it is carried away. 3. The cause is a diminution of the power to decompose the sugar which is introduced into the general circulation.

9. Zimmern * directs attention to the fact that hitherto, in interpreting the origin of diabetes, the muscles, where glycogen and sugar are formed, have not been taken into account, and, nevertheless, a muscle in repose, as we know, like the liver, stores hydrates of carbon in the form of glycogen in its tissue; during labor this glycogen is converted into sugar—that is, further compounded into sacreloctic acid, and finally into carboxic acid and water. That the muscle during its activity destroys even the sugar circulating in the blood, is most evident from the cures that are effected of many diabetics by means of bodily exercise methodically used.

10. Cantani † says that diabetes mellitus is a disease of the nutrition, in which, without an abnormal production of sugar, this is not consumed as fuel in the organism. This resistance that the sugar in diabetics shows against the process of oxidation may proceed from the fact that the ferment which disintegrates the sugar either is totally absent or operates in an abnormal manner on the sugar and metamorphoses it into a combination on which the oxidizing forces of the organism are wholly inoperative. According to Cantani, the blood-sugar, the paraglycose, of diabetics is different from the normal blood-sugar. As the material seat of diabetes, Cantani admits in the first stage the pancreas, even the digestive glands of the stomach and intestines; it is only indirectly that affections of the central nervous system, by influencing the chylopoietic organs, effect diabetis.

Stockholm, Sweden, March 19, 1883.

PROF. ERCOLANI’S RECENT INVESTIGATIONS OF THE ANATOMY OF THE PLACENTA.

BEING A REVIEW OF THREE LETTERS ADDRESSED BY HIM TO PROFESSOR ALBERT KÖLLIKER.

By Henry O. Marcy, M.D., Boston.

The author believes that a new confirmation, by new observations, of the results which he has for many years been

* Eklund.
† Otto Tunke, op. cit., S. 104.
‡ Ibid.
§ Ibid. 2
¶ Ibid.
laying before the Academy upon this subject, will be in
some degree acceptable to those anatomists who, in Italy
and abroad, have confirmed his investigations by their own.
He can not, however, fail to perceive that, notwithstanding
his publications, and those more especially of Romiti in
Italy, of Turner in England, and myself in America, the
great majority of anatomists and obstetricians continue to
hold as true the doctrines which others as well as himself
have shown to be erroneous.

It was in England that the observations made by the
author began really to enter the domain of science; and
this because the illustrious Turner, with repeated investiga-
tions and numerous works published from 1871 to 1876,
fully confirms all the fundamental observations which the
author had published as early as 1868. Thus it has hap-
pened that many of the observations which really belong to
him are attributed to Turner, and in the same way in Ger-
nany, those which he had much earlier made upon the so-
called roots of attachment of the fetal villi in the placenta
of woman are assigned to Langhans.

The author does not intend to reclaim for himself the
priority of these observations, which indeed others have al-
ready attempted; as, for instance, Romiti, affirming that
even illustrious German anatomists have published some of
his observations without, however, crediting him.

Still less does he propose to show how, especially by
some in France, an account of his labors has been rendered
in a manner truly strange and very far from true—for time
brings the remedy for these petty wrongs to which the vo-
taries of science in Italy have for years been accustomed.
In giving the results of his new researches, he has deemed
that it might be, therefore, proper to inquire with some
minuteness into the reasons which have led the opponents
to erroneous views, placing in relief the uncertainties and
the open contradictions which they are forced to accept as
truth in following doctrines opposed to his own observa-
tions.

Unhappily, among those who are adverse to the observa-
tions of the author must be reckoned one of the most dis-
tinguished of anatomists and embryologists, Albert Kolliker.
However regretfully, one is yet constrained to adopt toward
him the ungracious office of critic, and to combat the teach-
ings which he, the head of an illustrious and famous school,
has given, as well on the placenta of the mammifera as on
that of woman. This is so much the more painful to the
author because, when his actual observations are confronted
with the teachings of Kolliker's school, the discord appears
so serious and far-reaching as to give to some minds ground
for suspicion that the words used sound sharp, or less than
reverent, toward the great anatomist. But facts, not words,
make the contrast.

To remove even the shadow of this, which the author
would consider an injurious suspicion, and to give clear
and positive proof of the high esteem which he professes
for the eminent anatomist, he wishes to address to Kolliker
himself these new investigations in the form of letters,
knowing well that true and great scientists live only for the
search of truth and its development.

In the first of the letters the author shows the causes
by which the celebrated anatomical school of Kolliker was
led into errors of opinion concerning the placenta in the
non-deciduate and the deciduate mammiferous animals.

The first question which he discusses is: How and why
is it, since all recognize and assert that comparative anatomy
alone seems to clear away the doubts and the great ob-
scurity that surround the exact knowledge of the intimate
structure of the placenta in woman, and since all have pur-
sued the same path, that, at the end, they are conducted to
opposite conclusions? The author believes that it is be-
cause, though the way prescribed was the same, they yet
traversed it in opposite directions, the point which for the
one party was the beginning of the journey being for the
other party its end. Thus, Professor Kolliker, seeking to
elucidate the differences observed in the development of
the placenta in the mammifera, takes as the basis of his
opinions certain conceptions held as correct about the hu-
man placenta; while the author, laying aside every precon-
ceived idea, and ascending in his researches from the sim-
plest to the most complex forms of placentation observed
in the mammifera, availed himself of the knowledge ac-
quired to judge the more complex facts observed in the
placenta of woman, which he found identical in structure
with that of the superior simiae.

Entering into details, he shows that, in the opinions
held concerning the non-deciduate mammifera, the funda-
mental cause of error was this: that, to decide upon the
existence of the organ in the uterus of the gravid females
of the said mammifera, Kolliker set out with the precon-
ceived idea that, if existing, it must present certain char-
acteristics such as those exhibited in the human placenta
—that is to say, a circumscribed structure and much vas-
cularity, characters which are necessarily wanting in the
non-deciduates, where the placenta is diffused, or which do
not correspond with any exactness in cases where the pla-
centae are multiple, as in the ruminants.

The admission of the preconceived general principle
was, of necessity, followed by the error of affirming that
the placental organ was wanting in these animals; while it
was not the organ that was wanting, but there were want-
ning to the organ those characters of circumscribed mass
("mole") and great vascularity observed in the placenta of
woman.

This first error necessarily led to a second—namely, the
belief that, the placenta being wanting, the fetal villi were
received into depressions (glands) which were formed in
the swollen mucous membrane of the uterus.

On this subject the author refers to his past obser-
vations, which have had wide and repeated confirmation
through investigations made by others in Italy and else-
where, and by which it has been demonstrated that, after
the act of conception, in some of the non-deciduates from
the whole internal surface of the uterus, in others at some
points only of the surface, the epithelium falls off, and from
the denuded surface there takes place a new formation of
cellular elements (decidual), from which are formed, ac-
cording to the different animals, either crypts or true
 glandular follicles, into which the fetal villi enter; that
the said follicles, new-formed after the act of conception
has taken place, remain in the uterus during the whole period of pregnancy, and disappear after parturition, the internal superficies of the uterus (the epithelial stratum of the mucous membrane being renewed) thus resuming its condition prior to conception.

In the deciduate mammals, in which the placental organ has either the zonarial or the discoidal form, there exist the two general characters inferred from the human placenta; and here the fundamental cause of the errors taught by the school of Kölliker comes from the supposition that, in these animals, as well as in the human placenta, that organ was developed by a transformation of the pre-existing uterine mucous membrane, with this difference only: that in woman the whole uterine mucous membrane was transformed, while in the deciduates it was only that portion of the membrane in which the placenta was developed.

The new observations made by the author on the uterine horn of the *Myzura glis* (dormouse) in a state of repose, in the period of heat, during pregnancy and the forming of the placenta, and at various epochs after parturition, demonstrate more fully the fact, which he had previously remarked in gravid females of other mammiferous deciduates (rodents and insectivora)—namely, that in some of these it is the whole uterine mucous membrane that becomes swollen and enlarged in the period of heat, and that after the act of conception it is not only the epithelial stratum that disappears, but all the elements which compose the mucous membrane (submucous connective tissue, vessels, and glands) are completely destroyed to give place to a new formation of special cellular elements (decidual) from which the placenta will be formed. The new-formed parts being thrown off at parturition, the cavity of the uterus by degrees is clothed with a new mucous membrane, and so the uterus returns to the state in which it was before impregnation.

By these observations, which the author minutely describes and illustrates with plates, it is completely proved that in certain deciduates, at least, it is not a portion of the uterine mucous membrane that is transformed to produce the placenta, since this membrane, with its different component parts, is completely destroyed before the placental organ is formed. In other deciduates—as, for example, in the canidae and the felidae—the destruction of the uterine mucous membrane does not occur even in the places where the placenta is developed; the epithelial stratum alone disappears, and thus in these animals is witnessed a fact worthy of special notice, because it serves to explain the origin and the formation of the non-caducous stratum of the placenta in woman.

In the canidae and the felidae the uterine mucous membrane is furnished with a thick layer of loose connective tissue, in the midst of which stand the numerous and long utricular glands. The decidual new formation in the place where the placenta is developed closes their discharging apertures, and, as the secretion in them does not cease, the moisture separated becomes accumulated in their interior, and in the midst of the connective tissue they become deformed, and acquire a degree of dilatation truly enormous.

In woman are repeated the same facts in the place where the placenta is formed, but the local conditions differ, as we shall presently see.

- Returning to the deciduates, the erroneous belief that the placenta was in these derived from a partial transformation of the mucous membrane would necessarily lead, as it did, to other and not a few errors of a secondary order. These the author exposes, demonstrating the profound differences observed in the intimate anatomical structure of the placenta of different deciduates, as well in those having the zonarial as in the discoidal form: he rejects the general character indicated by the intimate structure of the organ for those mammifers—namely, that the two parts constituting the placenta are so intimately united that both are thrown off in the act of parturition, while in the non-deciduates only the facetal parts would be emitted, segregating themselves from the maternal parts.

This observation, which is due to Weber, is perfectly exact, but does not serve to distinguish the animals from each other. The author reviews the observations of others and his own, which show that in deciduates, as well in the zonarial as in the discoidal placenta, the relations between the two parts of the placenta are the same as are observed in the non-deciduates, which is of simple contact, and not of intimate union between the two parts.

Reviewing this first letter, it may be said that in the opinions held concerning the genesis and the structure of the placenta, both in the non-deciduate and the deciduate mammals, the school of Kölliker was led into erroneous conclusions from the preconceived idea that in all cases the mucous membrane of the non-gravid uterus took an active part, representing the maternal portion of the placenta as simply swelling or becoming hypertrophic in the non-deciduates, or becoming partially transformed in the places where the placenta is developed in the deciduates.

By his former and his recent investigations, however, the author, setting out from facts observed and followed in their minutest details, has arrived at the opposite conclusion, that neither the mucous membrane as a whole, nor any of the parts that enter into its composition, take an active share in forming the maternal portion of the placenta, and that in all cases this results from a new formation of special elements, to which the mucous membrane of the non-gravid uterus does not always serve as substratum.

An indispensable condition for the new formation is the denudation of the internal surface of the uterus, which is limited to the simple destruction of the epithelium in the greater number of instances precisely as was also observed in woman; but this indispensable destructive process extends in some of the mammiferous deciduates to all the parts that form the mucous membrane in the non-gravid uterus, and the new formation is, in this case, established directly upon the internal muscular surface of the uterus.

In the act, or subsequent to parturition, the new formation that constituted the maternal part of the placenta is always more or less carefully expelled from the uterus, and the process of renewal, in order to restore the internal superfluities of the organ to its state previous to conception, stands in direct ratio to the course of the aforesaid destructive process.
It is with the new-formed decidual elements that the villi or fetal vessels exclusively hold any relation.

In the non-deciduates this relation is one of simple contact; but this same relation has been likewise observed in mammiferous deciduates, whether they have the zonarial or the discoidal form of placenta. In all these cases the decidual elements acquire, as the pregnancy goes on, the form of a glandular organ more or less simple or complex; it is, therefore, not true that in the non-deciduates alone the fetal part separates itself from the maternal. In the mole, which is deciduate, with the discoid form of placenta, the intimate structure of the organ is that of a cotyledon in the ruminants.

In many deciduates, and in those in which the two parts constituting the placenta are intimately conjoined, the decidual elements are proliferous, but remain always in the state of cellular elements, and it is solely and exclusively with these that the vessels of the fetal part come into relation.

Without prior decidual new formation there can in no case occur the development of the placenta, whatever the form it assumes in the different species of mammals. Based upon mistaken observations of facts, the fundamental division of the mammiferous into deciduates and non-deciduates was accepted by zoologists.

On this important point, however, the author thinks no further discussion necessary, since the illustrious founder of the said distinction, Professor Huxley, has done him the honor of writing to him that he, too, has abandoned the distinction indicated. The nature of the present work, moreover, permits the author to touch merely, in passing, upon observations heretofore published, to show how the great differences of structure remarked in the placentas of vertebrate mammalia might readily reconduct to a unity of anatomical type—an anatomical unity to which the physiological unity corresponds—the fetal part, namely, or absorbent surface in contact with the maternal part or secreting surface.

(To be concluded.)

SIX SURGICAL CASES
TREATED IN THE
MEDICAL MISSIONARY SOCIETY'S HOSPITAL.

BY J. G. KERR, M.D.,
CANTON, CHINA.

CASE I.—TUMOR OF THE PAROTID SPACE.—A woman, forty-five years old, from the Province of Kwong-sai, was admitted to the Medical Missionary Society's Hospital, Canton, with a tumor of the right side of the face, extending from above the ear to the collar-bone, and from the corner of the mouth to the neck behind the ear. It was almost as large as her head, and had been growing for eighteen years, until now the weight made it very burdensome, and she was anxious to have it removed. About four years ago she went to a hospital at Hankow, on the upper Yangtse, when it was about half as large; but for some reason the operation was not performed. The outer and lower part of the tumor was ulcerated, and discharged a thin sanious pus. The tumor was excised on the 10th of August, Dr. Joseph Thomson assisting. The skin was loosely attached and easily dissected; but there were several enlarged veins, from which some blood was lost. The attachments in the parotid space were deep and strong, requiring careful dissection; but they did not involve the sheath of the vessels. The arteries and veins at the base of the tumor, constituting its blood supply, were, of course, large, and, with all possible precautions and as much rapidity of dissection as was admissible, the loss of blood was great. On the completion of the operation, the patient was very much prostrated from shock and loss of blood. The application of hot bottles, stimulants, and the elevation of the lower extremities, brought about reaction. In a few days convalescence was decided, and the wound healed favorably. In two weeks she was able to walk about, and cicatrization was almost complete. The wood-cuts, taken from photographs, show the appearance of the woman with the tumor and after its
removal. The weight of the tumor was four pounds. It was a glandular tumor, the irregularity of the surface indicating different lobes of which it was composed.

**Case II.—Tumor of the Parotid Space.**—The patient was a woman, thirty-seven years old, resident in the city. The tumor was located on the right side of the neck, was movable, and supposed to be an enlarged gland. On attempting to remove it, the attachments in the parotid space were found to be very strong, and the sheath of the vessels involved. In the dissection, the internal jugular vein was wounded in two places, and it was tied above and below the openings. The tumor was found to be cancerous, and it was impossible to remove the whole of it. The wound, however, healed, the ligatures around the vein came away in due time, and no unfavorable symptom occurred during the convalescence.

**Case III.—Hydrocele; Castration.**—A man was admitted with hydrocele, for the radical cure of which a few drops of strong carbolic acid were injected. The inflammatory swelling only partially subsided, and after two months it was decided to open the tunica vaginalis and close the secreting surface by granulation. On making the incision, September 25th, the testicle was found to be enlarged, disorganized, and one end converted into a dark gelatinous mass. It was at once excised, and the cavity healed by granulation. The disorganization of the gland was, no doubt, due to the carbolic acid, and, so far as one case goes, this shows the acid to be unsuitable for injection into the sac of a hydrocele.

**Case IV.—Excision of the Right Half of the Lower Jaw.**—A man, forty-three years old, from Shun-tak District, was admitted with a tumor involving the entire right half of the lower jaw. The tumor invaded the mouth, pushing the tongue over to the left side, and threatening to produce suffocation. The pressure of the tumor upon the teeth and alveolar processes of the upper jaw had pushed them out of position, so that the teeth were lying transversely across the roof of the mouth. The position of the tumor in relation to the deep parts at the base of the tongue could not be accurately determined; but, as it was steadily growing, and a few more weeks would certainly end in death, an operation was the only resource. It was performed, August 15th, with the assistance of Dr. Wales and Dr. Thomson. The deep attachments were such as to admit of dissection without injury to the important parts at the base of the tongue. The teeth of the upper jaw, lying across the roof of the mouth, were extracted. The tumor was fibro-cystic in structure, and weighed one pound and a half. There was much prostration after the operation, severe vomiting continued for forty-eight hours, and there was an offensive discharge from the wound; but a favorable change took place on the third day, and at the end of a week he was able to sit up, and left the hospital, cured, on the sixteenth day. He was seen again all right at the end of a month.

**Cases V and VI.—Burrowing Fistula of the Gluteal Region.**—Two cases of this disease have been under treatment during the year. It is not common in China, and must be rare in more civilized countries. One of the patients was admitted into the wards of the Medical Missionary Society's Hospital with both buttocks honey-combed with fistule, sanious pus discharging from numerous openings. The disease usually begins with fistula in ano, extending outward, first on one side and then on the other, until the buttocks, on one or both sides, and the sacral region, are honey-combed. The skin is much thickened and hardened. It is attached at numerous points to the subjacent cellular tissue, all the intervals being pus-secreting surfaces. The tendency of the disease is to spread. In this case syphilitic contamination was the special causative influence, and it has been so in most of the cases that have come under my observation.

The treatment consists in sitting up thoroughly all the fistulous passages in every direction, cutting away the unattached skin, and leaving the points of union between the skin and subjacent tissue as centers of cicatrization. It is necessary, when the extent of surface is large, to operate several times, and the case under notice required about six months' treatment. It is, of course, necessary to combine anti-syphilitic remedies with the incisions.

---

**A CASE OF STRANGULATED INGUINAL HERNIA WITH AN UNDESCENDED TESTICLE.**

By CHARLES M. CARLETON, M.D., NORWICH, CONN.

The notes of this case were kindly taken by Dr. Sidney A. Fox, who was associated with me in practice at the time. Charles M., aged twenty-three, single, and by occupation a farmer, came to me February 6, 1883, when the following points were obtained: He had had a right oblique inguinal hernia for the past ten years—supposed to have been caused by a kick in the groin. On making an examination, a large, painful tumor was found in the right groin, just internal to the external ring, and to the inner side of the tumor was a small, painful mass which proved to be an undescended testis. The patient stated that the hernia had been down for four or five hours, that it was growing larger and more painful, and that an attempt had been made to reduce it while he was partially under the influence of ether. He complained of pain in the region of the umbilicus, with almost incessant nausea and vomiting, and it was decided to etherize and reduce. Taxis having failed, everything being in readiness, it was decided to operate without delay. The operation was performed in the usual manner, and quite a knuckle of intestine was found, of a very dark color. After removal of the constriction the natural color returned, and the gut was replaced in the abdominal cavity.

It was deemed best to remove the testicle. The nerves (spermatic plexus) were carefully dissected from the remainder of the cord and divided with a scalpel. The cord was tied with a carbolized catgut ligature. The reason for not including the nerves in the ligature was to do away with the supposed danger of tetanus.

The wound was closed by interrupted sutures. An eighth of a grain of sulphate of morphine was given, and
the patient was directed to have a like dose every three hours.

**February 6th, 11.15 A.M.**—Pulse 72; temperature 98.5°.

F. About one pint of urine drawn with the catheter.

7th, a. m.—Pulse 72; temperature 98.5°. Patient has dozed nearly all night. No special pain or tenderness. Some tympanites. Has drank about three pints of milk.

P. m.—Pulse 94; temperature 100.7°. Ordered the dressings to be kept wet with tincture of calendula.

8th, a. m.—Pulse 84; temperature 98.7°. Slept about six hours. Coffee, milk, and gruel constituted the diet.

P. m.—Pulse 72; temperature 99.7°. Complains of pain in the lumbar region, and there is some tympanites. Ordered an additional dose of morphia.

9th, a. m.—Pulse 72; temperature, 98.6°. Has passed a very comfortable night. Three stitches were removed; union seemed to be perfect. Ordered morphin (½ gr.) every four hours instead of every three hours.

P. m.—Pulse 72; temperature 100°.

10th.—Pulse and temperature normal. Four stitches removed. Some tenderness on pressure in the groin, also some fullness.

11th.—Ordered two grains of quinine every six hours. Pulse and temperature normal. Allowed solid food. To take a teaspoonful of compound liquorice powder after 9 P. M.

12th.—Bowels moved twice—for the first time since the operation was performed. Ordered two teaspoonfuls of the compound liquorice powder.

13th.—Bowels moved twice. Last stitch removed, and union seems to be perfect. Patient allowed to sit up.

14th.—Sat up nearly all day. Fools quite well.

15th.—Dressed and down stairs. Walks about. Will be allowed to go to his home in the country in a few days.

It will be noticed that the temperature rose above 106° only once. The man's recovery was regarded as complete on the ninth day. No antiseptic precautions were used except to carbolize the instruments, together with my hands and those of my assistants.

---

**Book Notices.**

This issue of Dr. Richardson's well-known work marks the highest development of that distinctively modern enterprise, the publication of a cheap medical literature. We say the highest development, for we doubt whether the public has ever before been offered so much in the way of sterling quality for so modest a sum of money as ten cents.

It is too late in the day to notice this work otherwise than as regards this special edition of it; readers of the journal are already familiar with its scope and character. Suffice it to say that we have read these 520 pages of clear and correct typography with much care. We have discovered little that is open to unfavorable criticism or question. There is, perhaps, an occasional readiness to settle doubtful and difficult scientific problems off-hand, and we think the author's pessimism might have been judiciously learned. The treatise is ostensibly written for the general public, and, in our opinion, it will be of most value placed in the hands of the non-professional reader. We do not know of any work so well calculated to instill sound views as to the nature and causation of disease, and, if physicians will circulate this book among their patients, it will redound to their interests and to the interests of scientific medicine.

**Lectures on Cataract: Its Causes, Varieties, and Treatment.**

This little volume of 126 pages consists of a series of lectures delivered at various times to the students at the Westminster Hospital. They are prefaced by a brief anatomical introduction, and an account of the development of the lens. The author first defines what is meant by cataract, and then describes the different varieties. He then considers the various operations which have been attempted for the cure or removal of the cataract, beginning with that of enucleating or reclamation, and ending with Knapp's extraction by peripheral division of the capsule. He treats briefly of the antiseptic method of operating, and concludes with a short account of the treatment of cataract by the formation of an artificial pupil. The illustrations are fairly good, but they are not sufficiently numerous. The publisher's work is well done, the paper being good and the type clear.

**Books and Pamphlets Received.**

A Case of Primary Monomania (primäre Verrücktheit). By C. B. Burr, M. D., Assistant Physician to the Eastern Michigan Asylum, Pontiac. [Reprint from the "American Journal of the Medical Sciences."

The Baed Suture, etc. By David Prince, M. D., of Jacksonville, Ill. [Reprint from the "Annals of Anatomy and Surgery."

A Rectal Obturator. By David Prince, M. D., Jacksonville, Ill. [Reprint from the "St. Louis Medical and Surgical Journal."

Fourteenth Annual Announcement and Catalogue of the Woman's Medical College of Chicago. Session of 1883-84.

Fifth Annual Announcement and Catalogue of the Medical Department of Arkansas Industrial University. Session of 1883-84.

**The Hydrocele-Cat.**—M. Derrembrg lately related to the Société de Biologie, in Paris, a case in which the frightful cries of a patient with tubercular meningitis were stopped immediately, on three separate occasions, by a hypodermic injection of chloroform. Each time, as the cries ceased, a rhythmic spasm seized one of the patient's arms.

NEW YORK, SATURDAY, JULY 28, 1883.

AUTHORITY IN MEDICINE.

It is only with some qualification that it can be said, even at the present day, that there is no such thing as authority in medicine. It is true that none but the most hopelessly bennighted have taken to their hearts a particular hero by whom they suffer themselves to be led, or whose dicta they bring up as a final argument in conversation; but it is none the less the case that there is still too great a disposition to trust to the judgment of authors. Of course, this is to a certain extent unavoidable, and will probably never cease to be so. Readers very properly require to know, for instance, whether, in the first place, an author is truthful and fair-minded, and, in addition, whether there is good reason for supposing him capable of guarding against ordinary sources of error in the observation of natural and pathological phenomena. In other words, they demand that what he sets down as facts shall be in some sort guaranteed to them to be facts. Apart from a personal knowledge of the man, such a guarantee is usually sought in the position accorded to the writer by those of his professional brethren who are so situated as to be able to bestow upon him the stamp of their esteem. Now, the latter generally takes the form of a college or hospital appointment. Hence it happens that very few men who are unable to write a title or two of that sort after their names make much of an impression on their readers.

It seems quite probable that professorships are sought for in view of this consideration quite as much as from a desire to get fees from students or consultation calls from junior practitioners; and hospital appointments rather for the same reason than from a wish to enlarge the field for personal study. This is neither unnatural nor reprehensible, for men are perfectly justified in clothing their utterances with all the weight that their personality is fairly entitled to carry with it. Perhaps, too, the inordinate multiplication of hospitals and medical colleges is in great degree attributable to the same impulse. This result is certainly to be regretted.

It is particularly of this country that we are speaking, for nowhere else do medical writers take such pains to have titles printed after their names. Indeed, our brethren on the Continent of Europe rather affect the opposite extreme. Not only do they leave us in the dark as to their official positions, but the town in which an author lives is not uncommonly omitted, a bare initial serves alone to distinguish one from another, and among the French it is often only the surname that is given. Now, this difference can scarcely be owing to any diversity of human nature, for it has not been generally noticed that our European confrères were any more given to self-depreciation than ourselves. It must be simply that with them circumstances do not make it requisite that they should show their credentials whenever they choose to address their fellows.

There are several reasons why European writers do not need to introduce themselves to their readers, so to speak. To begin with, the mere fact of their membership in the profession is prima facie evidence that they are above suspicion, which, alas! can not be said of physicians in our own country, for here, besides the big hole for the old cat, there are little holes without number for the multitudes of kittens—in fact, what we are pleased to call the bulwarks of the profession is a mere basket-work—visible, but scarcely palpable. It may, indeed, be said with truth that this particular item in the count is being remedied steadily year after year; but we must not trust too much or too long to the operation of the natural causes that are conspiring to that end. Something definite ought to be done at once, and the signs of the times point to nothing so squarely as to the State examination for the degree.

But more operative, perhaps, than the status involved in the European license to practice is the fact that medical men of any noteworthy attainments in those countries soon become very well known to the great mass of the profession, while with us a man may be an admirable Crichton to his townsmen, and yet his name be entirely unknown beyond the narrow limits of a neighborhood. This diversity comes chiefly from the compactness of European countries, and the relatively small number of educational centers, together with the long period of time the student spends at those centers.

All these considerations, however, while they go far to account for the American demand that writers on medical subjects shall put forth some shadow of testimony to their fitness to be listened to, do not justify the approach that is very largely made to the days of old, when Hippocrates dixit was a conclusive argument. There is too little critical reading among us. An author's truthfulness and ability having been shown, a well-educated reader ought to be able—and not only able, but disposed—to gauge his writing at something very close to its real value. Yet the ease with which one man after another occupies the field, to the practical exclusion of lesser lights, goes to show that this is seldom done.

PERSONAL REPUTE IN THE PROFESSION.

In the foregoing article some of the causes were mentioned which, it is thought, serve to hinder meritorious medical work from meeting with general and early recognition among the profession in this country. Among those causes was included the lack of acquaintance among physicians of various sections, the result of which is that really valuable contributions to our literature are apt to be lightly esteemed, or even wholly ignored, simply from the general craving for more authority than logic. To know a man personally is generally to estimate him aright. It is on all accounts to be desired, therefore, that men's qualifications should be given a fair chance to be made known to their fellows by personal acquaintance or something of an equivalent nature.
Our country is so large that we can scarcely expect that in this matter we shall ever reach the degree of organization and that extent of personal knowledge of each other that are enjoyed by the profession in smaller countries. Much can be done, however, to mend matters. Perhaps it is not altogether an advantage to our national societies in the specialties that their meetings are held in different parts of the country each year. Indeed, the American Gynaecological Society seems to have come to that conclusion a few years ago, for it modified the plan somewhat, resolving to hold its subsequent meetings in a few of the large Eastern cities. The migratory feature is a gain to the members of these societies in one way, however, even if it gives rise to some falling off in the character of the scientific work they accomplish; for it brings them in contact with the general practitioners of various sections of the country, and makes them known in the most effective way.

Let one of these societies meet in a rural locality, for instance, and the meeting will be attended not alone by the members, but by the physicians of quite a large area. In a town of some magnitude, of course, the effect in that way is all the greater. Hence, what a man says at these meetings is not altogether buried in the volume of transactions or in the special journal that publishes the official report of the proceedings, although these publications circulate chiefly among men engaged in the same specialty. It is essential to the material success of a specialist that he be known and esteemed by general practitioners as well as by his brother-specialists, and, when he addresses the profession at large through the medium of the general journals, it is well that his readers should have already had some idea of who he is.

Some of the shortcomings of the American Medical Association—and so large a body can scarcely be expected to be free from them—have been imputed, and no doubt with a great deal of truth, to its changing membership as concerns the delegates, and to its peripatetic character. These elements do unquestionably bring it about that the work done in its sections is inferior to that done by the special societies, but, on the other hand, these very features tend powerfully to make a different set of men acquainted with each other year after year. And those sets are numerous. Quite beyond its scientific work and its political work, therefore, the association is a power for good in the profession. We are not of those who decry the association, for, if in no other way it accomplished any good result, its influence in co-ordinating professional work and in promoting pleasant and profitable relations between men from different sections, engaged in various subdivisions of the general labor, is inestimable.

THE YEAST THEORY OF DIABETES.

The minuteness with which Smollett traced "The Adventures of an Atom" may be said to have been quite outdone by astrological research of late years. In the one case, that easy-going and accommodating nag, the imagination, needing neither whip nor spur, had only to be patted on the neck, and a consistent yarn was evolved for the reader's delectation. In the other, facts, or what with more or less of reserve must be taken for facts, have had to be unearthed at great pains, submitted to all conceivable tests of their genuineness, and fitted together in such a manner as not to do violence to their natural relations. It is getting to be more and more uncommon for facts possessed of any special import to be stumbled upon, or even to be gathered in casually during a quest for those of other bearings; nuggets are not now picked up by the wayside, but hard quartz has to be crushed and forced, by dint of all the laborious processes known to man, to give up whatever may lie buried within it.

All this is only another way of saying that what we go on terming discoveries are constantly putting on more and more of the real nature of inventions. While the pursuit is thus made inexpressibly more tedious and wearisome, the advance made in the long run is more substantial, and greater satisfaction, if less glory, rewards the worker. The contrast is sharp between this state of things and that which obtained in Sydenham's time, for instance, when plausibility was the only passport needed for the doctrines of great men, and when those given out by men of less renown had but to run the gauntlet of criticism from rival theorists—a criticism that favored rather of a malicious animus than of any fair-minded devotion to the elucidation of nature.

But, notwithstanding the unquestioned fact that the great burden of modern progress is borne by the investigators, it happens now and then that they are found to have accumulated a mass of material that they have been unable to put to its full use, and some strong man with a gift for synthesis is needed to clear up the disorder. It seems as if the next great move in this direction would have to deal with the germ theory of disease; but the time has not yet come for this finishing touch to the natural history of the cryptogams. Whoever is so conduct the game as to avoid a stalemate must have all the pieces well in view, and there must be no lingering doubt attaching to the rank or the relative position of any one of them.

"If the yeast fungus is not then found to be a pawn masquerading in the semblance of a queen, abundant credit will fall to Dr. Eklund, whose ingenious exposition of the saccharomyces theory of diabetes is given in this number of the Journal. Not the least taking feature of the theory is the explanation it offers of the acetonuria of diabetes, assuming, of course, that diabetic coma really is due to acetonemia. There are few diseases that are more puzzling than diabetes, whether in their pathology or in their clinical history, and whoever makes even a rational suggestion toward the solution of its mysteries deserves some mitigation of the stern hold by which modern science binds her devotees down to the study of pure facts.

PRECAUTIONS AGAINST THE CHOLERA.

Now, as always when the question arises as to the measures to be taken against an anticipated epidemic, the newspapers are dwelling on the matter of the filthy condition of the streets, and in this country and Great Britain the most prominent topic of inquiry in connection with the possible access of
cholera is as to what sanitary condition various places would be found to be in should the disease visit them. It is all very well to attend to cleanliness, not only when an epidemic threatens, but at all times. But it is sheer folly to bring that consideration into the foreground as being of the slightest avail under such circumstances as an impending invasion of cholera. Cholera undoubtedly runs riot in filthy, but, unfortunately, it shows the same luxuriance in the cleanest of towns. The road to safety lies not in giving the disease a chilling reception on its arrival, but in not allowing it to arrive.

The deplorable feature in the tendency alluded to is the fact that it leads to neglect of the only measures that are of any real use. It even leads to depreciation of the value of quarantine measures. Public opinion, the utmost support of which is always needed in matters of sanitation, is thus lulled into indifference to the necessary restrictions on commerce, and fails to oppose the obstructiveness of trade. As the "Nation" lately remarked, quarantine may never yet have stopped the march of cholera. There is good reason to think, however, that it has. At all events, an extension of the quarantine idea is all we can depend upon to keep the disease at bay. It is, therefore, exceedingly satisfactory and reassuring to learn that our Government, at the suggestion of the Surgeon-General of the Marine-Hospital Service, has telegraphed instructions to our consuls at British ports to take measures for the sanitary inspection of vessels bound for this country. Over and over again have epidemics stolen a march on those who were busy in pooh-poohing the possibility of their arrival. While, then, as has before been stated in this journal, there is no present occasion for alarm, there is every occasion for vigilance.

MINOR PARAGRAPHS.

THE CHOLERA.

Up to the present time, Thursday, the cholera is not known to have crossed the Mediterranean, although there is a doubtful report that a few cases have occurred in Russia. Its ravages have increased in Egypt, however, and now cover a large extent of territory. Hundreds of its victims are dying daily in Cairo. Every European country, including Great Britain, which is said to be the only one not panic-stricken, is increasing its precautions against the importation of the disease. Spain has voted one million pesetas to defray the necessary expenses. The British Government has sent a corps of physicians to Egypt, and it is reported that a quarantine will be enforced at Dover and Leith. The action of our own Government, in regard to the inspection of vessels bound from British ports for this country, is recorded elsewhere. The Health Officer of the Port of New York is represented as being confident of his ability to prevent the infection passing his quarantine. The vessel which lately proceeded from the New York quarantine station to New Haven, laden with Egyptian rugs, turns out to have left Egypt long before the outbreak of cholera took place, and it is thought she may be dismissed from consideration as a source of danger. As a general sanitary measure, the city of Chicago has added $10,000 to its usual appropriation for the use of the Health Department.

In Egypt itself there are indications, at last, of the speedy enforcement of proper sanitary measures. The cordons around Alexandria has been drawn closer, and hospital and ambulance facilities are being improved at Cairo. It has been decided that all refugees from Egypt must now undergo a sanitary inspection before being allowed to leave. A cable conveying a portion of Alexandria with drinking-water has been found to run through a cemetery, where corpses are washed in its waters.

It is reported that several of the European powers are negotiating for an international sanitary board, to sit either at Geneva or at Lugano, and a bill has been introduced into the French Chamber of Deputies appropriating 50,000f. for the expenses of the proposed scientific investigation of the Egyptian epidemic.

YELLOW FEVER.

The recent rumor of an outbreak of the disease at New Orleans is denied officially. Various commercial bodies in that city have asked the Government to prohibit the entrance of vessels from infected ports into the waters of the State, and to forbid all communication between Ship Island and the coast. The State Department has directed our consul at Vera Cruz to advise commanders of vessels bound for American ports to call at Ship Island for inspection, to avoid being sent there by the health authorities of their ports of destination.

The steam-ship City of Washington, from Vera Cruz, arrived at this port on Wednesday, having called at Havana, where she landed passengers sick with yellow fever, and took other passengers on board. She is discharging her cargo at the quarantine station, and her passengers were to be allowed to come to the city on Thursday. The mail matter was taken off at once. A death from yellow fever has taken place on board a British steamship in quarantine at Craney Island, near Norfolk, Va. In consequence, the Surgeon General of the Marine-Hospital Service has directed that she be anchored farther away, and all foreign vessels entering the neighboring waters will be stopped and boarded by a health officer.

SERIOUS CHARGES AGAINST A PHYSICIAN.

The "Tribune" publishes statements that, if true, bring to light certain practices on the part of Dr. W. F. Thomas, of Madison Street, going to show that he has been guilty of a series of questionable practices bordering on fraud. The charges are, in brief, that the doctor, representing himself as the president of a "Fresh Air Fund," makes appeals systematically, in person and by circular, to various citizens, and that contributions made in response to such appeals have been deposited to his own credit in a bank. It is stated, furthermore, that the circulars contain the names of gentlemen who say they have never heard of the scheme. The drift of the "Tribune's" article is, that Dr. Thomas's "Fresh Air Fund" is a myth, and that the doctor deliberately imposes upon the public. Dr. Thomas is well known in the profession, and we trust it will be shown that his vagaries have not been prompted by any intention to defraud those who have been annoyed with them.

ANATOMICAL DATA FOR THE ARMY MEDICAL CORPS.

In a circular issued by the Surgeon General of the army, for the information of the medical corps, the anatomical data formulated by Dr. Bowditch, of Boston, in a report presented before the Massachusetts Medico-Legal Society last year, are given, together with a modified form of Dr. Bowditch's scheme for recording post-mortem examinations. The latter embodies many useful hints for the conduct of autopsies. The circular contains also a table of the average weight and dimensions of the body as a whole, and of the various internal organs, at different ages,
abridged from tables compiled by Dr. Robert Boyd, of England; a table of the approximate volume of organs and the circumference of arteries, condensed from Benecke's "Anatomischen Grundlagen der Constitutionenannahmen des Menschen"; and a table giving statistics of stature and weight, mainly from Robert's "Manual of Anthropometry" and Colonel Baxter's observations on nearly 149,000 American white males.

The document as a whole is a fresh exemplar of the gratifying spirit evinced by the Surgeon-General's office to promote creditable work by the medical corps.

THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.

The first number of this new weekly publication has reached us. It is dated July 14, 1883. It is largely taken up with the minutes of the meeting of the association. So far as we can judge from the first number, the journal will be a fitting representative of the association.

A MEDICAL PLEASURE PARTY.

Some of our Philadelphia brethren, including Dr. W. M. Welch, Dr. C. J. B. Nancrede, Dr. Forbes, of the Jefferson Medical College, Dr. J. V. Shoemaker, and Dr. Carl Seller, lately made up a party to go to the town of Cresson in quest of recreation. The occasion was a meeting of the Juniata Valley Medical Society at Cresson. Dr. Shoemaker had charge of the arrangements, which fact is an ample assurance that the party was handsomely provided for.

THE IOWA STATE MEDICAL REPORTER.

This is the title of a sixteen-page monthly journal, edited by Dr. F. E. Crightenden, Dr. C. M. Hobby, Dr. L. C. Swift, Dr. D. W. Snouse, and Dr. J. T. Priestley, and published at Des Moines. The first number, for July, contains three original articles, several clinical contributions, and a variety of editorial matter. The "Reporter" is "edited expressly for the medical profession of Iowa."

A CLINICAL RECORD OF DERMATOLOGY.

Under the title of "Album Clinico de Dermatologia," the enterprising conductors of the "Revista de Medicina y Cirugía Prácticas," of Madrid, have begun the publication of an illustrated periodical devoted to dermatology. The third number, now before us, contains an excellent picture portraying the affection termed tinea pelada (alopecia areata). A brief description of the case is appended, in which the author, Dr. Perez Ortiz, mentions that he found the Microsporum Audouini, which fact, taken in connection with the title he applies to the affection, seems to show his acceptance of the parasitic theory of its aetiology.

THE BRISTOL MEDICO-CHIRURGICAL JOURNAL.

This is a new journal, published (semi-annually at present) under the auspices of the Bristol Medico-Chirurgical Society. The first number, for July, 1883, contains 143 handsome octavo pages, and is quite freely illustrated. The original papers are: The Proofs of the Existence of a Phthisical Contagion, by R. Shingleton Smith, M.D., etc.; Clinical Evidence against the Contagiousness of Phthisis, by E. Markham Skerritt, M.D., etc.; The Cardiograph in Medicine, by G. Munro Smith, L.R. C.P., etc.; and Surgical Out-Patient Notes, by W. H. Harsant, F.R.C.S. These are followed by a goodly array of "clinical records," book notices, and abstracts. We congratulate the editor, Mr. J. Greig Smith, on the promising start the new journal seems to have made.

THE MORTALITY AMONG CONVICTS.

Some statistics have recently been published giving the death rate in the principal penitentiaries or state prisons of the various States, and the comparison is curious and to a degree inexplicable. The proportion varies from three in every thousand in Wisconsin to seventy-seven in Mississippi. Of the prisons of this State, the rate at Sing Sing is a little less than seven, at Auburn twelve, and at Clinton over twenty. In Massachusetts the rate is fifteen, in Maine the same, in Vermont twenty-five, and in Connecticut fifteen. In Pennsylvania, the rate is six in the Western Penitentiary and fourteen in the Eastern. It has been the custom in some of the Southern States to let out convict labor to the highest bidder, and this has resulted in a frightful death rate, although the figures are not easily ascertainable. The highest rate in a northern State is twenty-six, in New Hampshire. These variations are so remarkable that there does not seem to be any comment possible. In some of the institutions presumed to be the best managed, the death rate is exceedingly high, while in others of apparently equal grade it is low.

NEWS ITEMS.

The Nuisances at Hunter's Point.—At last, it seems that an effort now being made to abate the nuisances on Newton Creek is likely to succeed, the State Board of Health having taken the matter up, after the failure of the New York and Brooklyn boards. Thirty-two establishments have been shown to be nuisances, and, unless some miscarriage of justice takes place, they must be abandoned or the character of their operation must be radically changed.

An Outbreak of Disease among Horses, the precise nature of which is not yet apparent, is reported from Connecticut. Three horses on a farm in West Hartford, all there were on the place, were suddenly attacked, and died within a few hours. A veterinarian, Dr. Bryden, made an autopsy in one of the cases, and is said to have found that pneumonia was the cause of death.

A Death from "Soothing Syrup" having occurred in Brooklyn, the coroner's jury have very sensibly recommended the passage of a law by the Legislature forbidding the sale of such preparations except on physicians' prescriptions.

American Pox in Spain.—It appears that the Spanish Government, more just and discriminating than some of its neighbors, has not prohibited the importation of pork from this country, but has simply taken proper measures to prevent the entrance of diseased pork.

Leprosy in Egypt.—In addition to the cholera, leprosy is said to have become very prevalent of late in the neighborhood of Damietta.

The Training of Nurses in Pennsylvania.—At the recent meeting of the Medical Society of the County of Allegheny, Pa., a committee was appointed to report a plan for the efficient training of nurses in the county.

The Massachusetts State Board of Health, Lunacy, and Charity.—Dr. Eber A. Dean, of Brockton, has been made a member of the board.

Cholera Morbus in Connecticut.—Two fatal cases having occurred in Hartford last week, together with a number of
The Summer Sanitary Corps of the Board of Health.—The vacancy occasioned by the death of Dr. Milligan Patchin has been filled by the appointment of Dr. E. E. Hunt.

The Registration of Deaths in Brooklyn.—On Tuesday a physician was arrested on a charge of failing to report the death of an infant to the Board of Health.

Professor O. C. Marsh, of Yale College, has been made a member of the Munich Academy of Sciences.

Dr. King, of Dublin, the well-known obstetrician and gynecologist, has received the degree of Magister in Arte Obstetrica (M. A. O.) from the University of Dublin.

M. Dujardin-Beaumetz has been made an officer of the Legion d'Honneur.

OBITUARY NOTES.

Milligan Patchin, M. D.—On Sunday, the 21st inst., Dr. Milligan Patchin, a young physician of quite unusual promise, died suddenly, under peculiarly painful circumstances. Dr. Patchin, who was living with friends, at No. 427 East Fiftieth Street, in New York City, a few minutes after retiring to his room at about half-past nine in the evening was found in a moribund condition, having been wounded by a pistol-ball which passed through the heart and a portion of the left lung. The lady with whom he was living had spoken to him at the door of his room at about half-past nine, and had noticed nothing unusual. A few minutes later, hearing a heavy fall, she entered the room, and found Dr. Patchin in a dying condition, lying upon the floor, and wounded as described. The first impression made upon the mind of herself and other friends was, that Dr. Patchin had committed suicide, although it was the mode of death only that gave color to this supposition, there being no imaginable cause for an act of self-destruction. Careful examination, however, at the inquest, showed clearly that the discharge of the pistol must have been accidental. There was no discoloration of the clothing from burning powder, and the discharge must have taken place at some distance from the body. This, with other circumstances developed at the inquest, left no doubt with regard to the accidental character of the injury, relieving the friends from the additional distress which would have attended a death from suicide.

Dr. Patchin was born in Buffalo, New York, December 16, 1860, and was, therefore, in the twenty-third year of his age. Between the ages of nine and fifteen he was at school in South Germany. He afterward spent nine months at school near Paris, and became a complete master of the German and French languages. From the age of sixteen to nineteen he studied under a tutor near the Eton school in England. Returning to the United States, he passed his entrance examination for Columbia College, but never joined his class. For several years he had shown a decided taste for the study of medicine, which was not encouraged by his relatives, on the ground that his health, although not feeble, was, at that time, far from robust.

In 1880 Dr. Patchin began the study of medicine at the Bellevue Hospital Medical College, graduating in the spring of 1883. During this time he was a close and enthusiastic student, spending two of his summer vacations in desultory work at different hospitals in England. At his final examinations he presented himself as a competitor for one of the four places at the disposal of the college, as intern in the Bellevue Hospital. In this competition he was successful, ranking number two on the list, and receiving a total mark of thirty-four out of a possible thirty-five. In order to go upon the medical service in the hospital, which he preferred to the surgical service, he exchanged with the successful candidate next below him in rank, and would have entered the hospital in October of the present year. On July 9th he was appointed one of the temporary assistant sanitary inspectors under the Board of Health, and was serving in this department at the time of his death.

It is evident, from this account, that it is no empty tribute to the memory of Dr. Patchin to say that he was a gentleman of unusual attainments in his profession. He was peculiarly gentle and modest in his character and manner, a quality which endeared him to his teachers and fellow-students. The moment he began the study of medicine he seemed to have entered upon his true vocation in life; and his chief pleasure was in his professional work and associations. His hospital appointment and many little successful achievements which he made in practice after his graduation were sources to him of much unobtrusive pride and gratification. Few young men have entered the profession with more flattering prospects; and his untimely death will be much regretted by all who remember the persevering, gentle, and unassuming student, just entering upon what promised to be a bright and useful professional life.—A. E., Jr.

W. B. Rinzer, M. D., of Cleveland.—Dr. Rinzer died suddenly on Saturday, the 21st inst. He was the president of the Cleveland Microscopical Society.

George W. Fisher, M. D., of Baltimore.—Dr. Fisher's death is announced in a brief dispatch to the newspapers. He was a son of Dr. George J. Fisher, of Sing Sing, New York.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

The nineteenth annual meeting was held at the Hotel Katterskill, Catskill Mountains, N. Y., July 18 and 19, 1883.

First Day, Wednesday, July 18th.—Morning Session.

The meeting was called to order at 10 a. m. by the President, Dr. Henry D. Noyes, of New York, who made a few congratulatory remarks, and then appointed the following:

Committee.—Committee on Bulletin: Dr. F. R. Loring, of Washington, and Dr. E. W. Bartlett, of Milwaukee. Business Committee: Dr. John Green, of St. Louis, Dr. E. Greening, of New York, Dr. O. F. Wadsworth, of Boston, Dr. S. Theodore, of Baltimore, and Dr. E. Dyke, of Newport.

The Treasurer's Report was read and, after being audited, adopted.

NOMINATIONS FOR MEMBERSHIP.—Dr. Charles S. Turnbull, of Philadelphia, Dr. Miles Standish, of Boston, Dr. J. L. Thompson, of Indianapolis, Dr. W. T. Bacon, of Hartford, Dr. Stephen O. Ritchie, of Washington, and Dr. John Van Duyn, of Syracuse, were nominated.

New Members.—Dr. B. E. Fryer, U. S. Army, Fort Leavenworth, Kan., Dr. J. A. Andrews, Clifton, N. Y., Dr. L. Western Fox, of Philadelphia, Dr. J. A. Lippincott, of Pittsburg, Dr. J. L. Minor, of New York, and Dr. E. E. Hoyt, of Portland, Me., were elected to membership.
PROCEEDINGS OF SOCIETIES.

Invited Guests.—Dr. T. Y. Sciphen, of Newark, N. J., Dr. R. H. Johnson, of Philadelphia, Dr. Miles Standish, of Boston, and Dr. Swann B. Burnett, of Washington, were invited to attend the sessions.

The INFLUENCE OF COLLEGE LIFE ON REFRACTION.—A paper on this subject, by Dr. Haskel Delhi, of Boston, was read by Dr. Miles Standish, of Boston. In two hundred and fifty-four instances the author had been able to trace the refraction through the whole term of four years. The examinations were all personally conducted with glasses, and in the majority of cases, certainly in all doubtful ones, with the ophthalmoscope. The results given were obtained with glasses. The use of atropine had been entirely impracticable, as the students could not have been allowed, even temporarily, to be disabled from the active prosecution of their studies. Dr. Derby recorded degrees of ametropia as slight as 0.5°, but nothing less. The average age of those examined was: at entrance, nineteen years; at graduation, twenty-three. The number of cases was small, it was true, but this was one of the few attempts yet made to trace the movement of refraction among the more highly educated during this particular period of life, and for a continuous term of years. The general results were: Hypermetropia, at entrance, thirty-nine; at graduation, forty-seven; myopia, at entrance, ninety; at graduation, one hundred and twenty; emmetropia, at entrance, one hundred and twenty-five; at graduation, eighty-seven. He found under the head of manifest hypermetropia, of which there were thirty-nine cases at entrance, that one changed to myopia, two diminished, twenty-seven remained stationary, and nine increased. Of myopia there were ninety cases; thirty-two remained stationary, and fifty-eight increased. Emmetropia: The observations concerning this class possessed peculiar interest, the results somewhat mitigating against theories generally accepted. One hundred and twenty-five persons were emmetropic at the time of entrance. Of these, eighty-six remained emmetropic, while ten became hypermetropic, and twenty-nine myopic. The average age of the latter was very nearly nineteen at entrance, twenty-three at graduation. The average myopia developed amounted to nearly 1° (1892). So far as these figures went, they tended to show, first, a large amount of myopia, even in this country, among the educated classes. It was difficult to compare Dr. Loring's figures with these, because Dr. Loring's statistics were based on observations made between the ages of six and twenty-one, whereas these observations were made between the ages of eighteen and twenty-three. But all researches at the latter age went to prove that at least half, or very nearly half, the educated community were myopic, in this as well as in other countries. Moreover, contrary to the impressions so long entertained, myopia might be acquired at or near twenty years, from the same causes that produced it at an earlier age, and it might progress until the course was completed.

The paper was discussed by Dr. David Webster, Dr. W. F. Mittensohn, and Dr. E. Gruening, of New York (the latter calling special attention to the use of the term dioptric, urging that some uniform mode of spelling be adopted), Dr. W. H. Carmalt, of New Haven, Dr. L. Little, of Philadelphia, and Dr. Hutchinson, of Utica.

Some Improvements in Instruments and Appliances for CATARACT Operations.—Dr. Russell Meredith, of Baltimore, read a paper with this title. He exhibited an ophthalmostat, or a self-holding eye forceps, and an eye speculum, which were modified from those exhibited to the society in 1874. The distinguishing features of the speculum were "absence of spring and set-screw." The change in the ophthalmostat was such that it seized the conjunctiva in a vertical fold, rotating the eyeball without dragging it, and three little hooks were substituted for one pair, which secured greater steadiness. The new instruments consisted, first, in the combination of Graefe's knife, and to end, with de Wecker's scissors; second, a combination of iris forceps with the cystotome and shallow speculum. The advantages stated for these instruments were that an assistant was dispensed with, and that seven instruments were reduced to three for the modified linear extraction of cataract. Dr. Murdoch also exhibited a bandage which could be quickly made and easily applied.

Dr. Gruening, of New York, thought that outside of the limits of civilization such complicated instruments might be useful, but that within those limits they should be discarded entirely, and that a cataract operation should not be undertaken without an assistant. Concerning the bandage, he thought an ordinary flannel bandage could not be replaced by anything yet brought forward. No bandage could produce the pressure that could be got from the flannel roller. It was necessary to immobilize the eye, and this could not be done by any substitute for the ordinary flannel bandage.

The President remarked that he had had some experience in the use of the little forceps in fixation, and had long ago discarded the instrument because it did not give so much control over the eye as one might imagine. He had concluded that the operator's hand should guide the forceps.

Dr. Murdoch was well aware the gentlemen in New York could obtain an assistant at any time, but he thought there were occasions elsewhere when it was impossible to secure one, and the instrument had been devised especially to meet such emergencies.

Dr. Theobald, of Baltimore, believed that the eye could not be immobilized by any bandage whatever which was at all permissible, and that there was a decided objection to the long flannel bandage, especially during hot weather.

Dr. Gruening would not insist upon the flannel bandage, but he would insist upon the long bandage, and of late he had used gauze wet with water. He believed that the eye could be immobilized perfectly if the bandage were properly applied. The first thing was, to fill up the orbital depression so that when the hand was placed over it the brow and the bridge of the nose were not felt, but the hand rested entirely upon the pad, and, upon such a pad, pressure with the bandage could be made to render the eye quite immobile.

Dr. Theobald thought if Dr. Gruening would apply the bandage, in the manner described, to his own eye he would find that the eyeball had not been rendered immobile.

TWEEZE OF THE INS.—Dr. Henry S. Schell, of Philadelphia, reported the case of a boy, nine years of age, who applied for treatment at the Will's Eye Hospital, August 29, 1881. The left eye had been painful for four days, and showed the general signs of ordinary plastic iritis. Atropine and mercurial ointment were prescribed. On the 16th of September no effect had been produced. In the latter part of October the boy came to the Children's Hospital, with well-marked cedalgus in the second stage. There was a distinct history of phthisis in the mother's side. The left eye was still somewhat painful, the pupil was immobile, there was a ring of circumcised injection, and projecting from the nasal side of the pupillary margin was a small, yellowish-white nodule of the size of a pin's head and tinged with pink. This gradually increased in size. The hip-joint disease progressed. The eye was enucleated, and was examined by Dr. G. B. Lawrason, of New Orleans, who reported that it consisted of two or three tubercular masses imbedded in inflammatory product. The tubercles seemed to have developed in the organized inflammatory product, which nearly filled the anterior and posterior chambers.
The President said that within the last year a case had been under observation in New York which illustrated the difficulties in diagnosis. The patient was four years of age, and the gross appearances presented by the eye were absolutely indistinguishable from a glaucomatous condition or a metastatic choroiditis. The patient continued under observation for several weeks without much progress in the disease. The eye was then enucleated, and the disease was found to be tubercular. It was felt at the time, by those who examined the patient, that, in some cases, the differential diagnosis between glaucoma and tubercular disease was impossible.

Tuberculosis of the Ciliary Muscles and Iris.—Dr. O. F. Wadsworth, of Boston, reported a case occurring in a girl three years and a half old. Dr. Hasket Derby, of Boston, had seen the patient when the process had lasted two weeks, and regarded the case as one of kerato-iritis. The pupil contracted, and remained so in spite of atropine. The cornea was hazy. The lids were natural. Afterward, when Dr. Wadsworth saw the patient, the cornea was hazy, the conjunctiva was moderately congested, there was no marked ciliary congestion, there was a good anterior chamber, and the pupil was of good size. The patient died about six months afterward. The eye after it was removed contained a mass about six millimetres in thickness, the vitreous was replaced by serous fluid, and there was nothing of the lens to be seen. The iris and choroid were in place, and behind the mass. Microscopical examination, made by Dr. Ernst, of Boston, showed that the growth was tubercular, and contained bacilli.

The paper was discussed by Dr. Prout, of Brooklyn, and Dr. Webeet, of New York.

A Personal Experience with Prismato Glasses.—Dr. S. F. McFarland, of Oxford, N. Y., read a paper in which he stated that during his boyhood he had a slight divergence, occurring and disappearing at times, although seldom sufficient to attract attention. Still, he had the full use of his eyes, could judge of distances as well as others, and was even expert in sports requiring binocular vision. He had no inconvenience during his studies, always enjoying the greatest comfort during the most severe and protracted application. During the autumn of 1862 he contracted typho-malarial fever in the army, and after recovering found that he had lost the full and comfortable use of his eyes, but felt the usual pain and annoyance attending a futile effort to use both eyes in conjunction, so that he was compelled finally to discontinue reading almost entirely, until, in January, 1866, he consulted Dr. Noyes, who gave him plain prisms of 7° each, bases inward, for distance, and 5° each, with +36 spherical for reading. At that time he had been nearly three years unable to obtain binocular vision even for a moment, but at once he was able to see distinctly. He had never discontinued their use. They had been varied from time to time, but he had always adhered to the prisms. He could not maintain continued binocular vision, but could obtain and retain it long enough for an iridectomy, or the extraction of a cataract, or even a very protracted operation, although with pain and very distressing lassitude afterward. Without the prisms he could not do these things, insomuch as slight differences in distance would not be appreciable. With bifocal sphero-prismatic glasses he was able to do all his office work without changing, and with a reasonable amount of comfort.

The Apparent Curvature of Surface produced by Prisms.—Dr. O. F. Wadsworth, of Boston, read a paper in which he remarked that the phenomenon was very familiar that when we looked through prisms with a plane surface, with the bases inward, the surface appeared convex, and with the bases outward it appeared concave. He had not met with any exception, and the communication was intended to explain, and was the theory which had been worked out by Dr. Pierce. It was illustrated with diagrams.

Sympathetic Neuro-retinitis.—Dr. J. A. Spaulding, of Portland, Me., read a paper, in which he reported a case. He first referred to the works of Mantzner and Knies, whose views were so diametrically opposed, the latter believing that the so-called cases of sympathetic neuro-retinitis were open to criticism. It seemed desirable, therefore, to publish and thus to offer to careful criticism every case of apparent sympathetic inflammation of the retina and optic nerve (either alone or combined). And above all did this appear necessary when we had, as at present, to offer one in which, so far as accurate and repeated examinations had revealed, the retina and optic papilla of one eye underwent inflammation after an injury to its mate, while at no time were there ever any visible signs of inflammation of any portion of the uveal tract. The patient was a Danish woman, fifty-six years of age, healthy in every respect. On the 6th of January, 1883, she was struck in the eye by the horn of a cow, which rendered her at once and for ever totally blind in that eye. The patient saw a flash of light, and then the sight was gone. Seven weeks after the injury to the right eye, the patient, much reduced in health by the pain and irritation in the right eye and its neighborhood, came to Dr. Spaulding. On the 20th of March, about four weeks after she was first seen, the right eye was enucleated. The case progressed favorably, and the patient was sent home. No medical treatment was adopted. The result appeared to justify the idea of the truly sympathetic nature of the neuro-retinitis in the left eye, for the sight gradually returned to the remaining eye. Pain in the head disappeared with considerable rapidity. July 14, 1883, examination with the ophthalmoscope revealed the left eye normal, vision 5/6. The presence of neuro-retinitis with total loss of vision in the eye five weeks after an injury to the other, and without any other visible or possible cause, indicated the sympathetic nature of the disease. Irises in any form was excluded as the possible cause of the difficulty in the left eye. The removal of the eye was accompanied by troublesome hemorrhage, for which two vessels had to be tied. A discussion followed on the management of hemorrhage in such cases, Dr. Webster, Dr. Prout, Dr. Mittendorf, Dr. Williams, Dr. Dyer, Dr. Green, Dr. Knapp, and the President taking part.

The paper was further discussed by Dr. W. W. Seely, of Cincinnati, and Dr. F. Bellier, of Montreal, Canada.

Thirty-five Cases of Qatarract Extraction were reported by Dr. Webster. All the operations had been performed at the Manhattan Eye and Ear Hospital. A brief clinical history of several of the most interesting cases was given.

The paper was discussed by Dr. Heyl and Dr. Strawbridge, of Philadelphia, Dr. Thorwald, of Baltimore, and Dr. Carmalt, of New Haven.

Notes on Ocular Therapeutics.—Dr. W. W. Seely, of Cincinnati, read a paper in which he directed attention, first, to the use of yellow oxide of mercury in external oculor troubles. Ten grains to the ounce of the vehicle was the best for all purposes. The less bichloride the preparation contained, the less pain it caused in conjunctival affections. Where there was profusion of tears, such as to wash a salve out, it was well to substitute essence or the bichloride in solution, to contract the blood-vessels. The strength of the bichloride solution that seems to answer every purpose was one grain to sixteen ounces of water. The application was entirely painless, and had often, in his hands, subdued a violent acute catarhal conjunctivitis, after from one to three or four thorough drenchings of the conjunctiva. In cor-
neal affections he used a four-grain solution of eserine once a day, and believed that it acted altogether better than more frequent applications, either of the same or of a weaker solution. This remark applied to all cases of cases. For the reduction of intraocular tension, eserine had with him done away entirely with paracentesis. Every one had met with cases of iritis in which atropine did not act promptly and satisfactorily, possibly because of the extreme vascularity of the iris. In such cases, instead of doing a paracentesis, and extracting blood, he instilled once a day a few drops of a four-grain solution of eserine. The habit of instilling eserine once a day in iritic cases had become a routine practice with him, the patient at the same time using the mydriatic in the ordinary manner. In more than one case he had seen adhesions yield to the combined use of a myotic and a mydriatic, that had resisted the latter alone. Iritis was the only disease in which he employed a mydriatic as a fundamental remedy. Eserine was the remedy par excellence in corneal affections. In cases in which mydriasis was necessary it could be produced perfectly, and still the satisfactory effects of the myotic be maintained.

Dr. McKay had used yellow oxide of mercury with very favorable results in conjunctival troubles. Dr. Guernsey said the alternate use of mydriatics and myotics for breaking up adhesions was not entirely new. He had resorted to it as long ago as 1898. He regarded the use of eserine instilled instigating as an extremely dangerous practice.

Dr. Knapp thought the alternate use of eserine and atropine was advantageous in some forms of iritis, especially the serous variety. Again, where there was increase of pressure, which produced intense pain, as in certain cases of glaucoma, the pain was considerably relieved by eserine. In serous iritis the pressure was sometimes intense, and he thought that eserine could be so regulated as to prevent the noxious effects of the drug.

Dr. Seely said he did not speak of the alternate use of eserine and atropine, but wished simply to speak of the use of eserine once a day for the purpose of contracting the blood-vessels, of course maintaining mydriasis with atropine. He had never seen a case in which eserine had produced iritis.

The paper was further discussed by Dr. Kipp, of Newark, Dr. Knapp, and Dr. McKay.

Evening Session.

The Treatment of Detachment of the Retina.—Dr. W. F. Mittenberg, of New York, read a paper on this subject. During the last three years he had treated several very extensive detachments of the retina in patients that had only one useful eye. Although no new remedy or new method had been used, it was the combination of the different plans devised for the treatment of this affection, and the mode of administering the remedies, that had led to success. After briefly referring to the causes of detachment of the retina, the writer stated that the object of treatment must be: 1. To keep the eye as free as possible from all irritating influences, which was best done by closing both eyes, or by putting the patient into a dark room. 2. To keep the eye as quiet as possible, avoiding all accommodative efforts, and for this purpose the eye must be kept under the influence of a mydriatic. 3. To place the absorbents in the most favorable condition by means of a pressure bandage, and he had found elastic pressure with a rubber bandage of the greatest assistance. 4. To hasten the absorption of the effused fluid, if this were the cause of the detachment, by the use of jaborandi or pilocarpine. He had given a hypodermic injection of one fourth to one sixth of a grain of pilocarpine early in the morning, and then kept up the diaphoresis by the use of an infusion of jaborandi leaves, from forty grains to one drachm in twelve ounces of water, administered in wineglassful doses during the afternoon and evening. This treatment should be kept up for three or four weeks. He had not seen a single case in which the remedy administered in this way had to be discontinued on account of unpleasant symptoms. If the detachment complicated a specific chorioiditis, or if it followed a serious iritis demanding specific treatment, this could be used at the same time with the other remedies mentioned. In these cases the disease yielded, as a rule, sooner than in others, and it was not necessary to push the pilocarpine to so great an extent. Dr. Mittenberg then reported in detail three cases, all of which had been successfully treated. They tended to show: 1. That in marked detachment of the retina the energetic use of jaborandi and pilocarpine would do good, especially if the patient could be kept under the influence of the drug during the entire day, and for a period ranging from twenty to thirty days. 2. That the elastic bandage must be used at the same time. 3. That the patients must be kept upon the back for most of the time. 4. That the use of atropine, which caused no inconvenience, should likewise not be neglected.

The paper was discussed by Dr. Geesink, Dr. Little, Dr. Andrews, Dr. Webster, Dr. Thobald, and Dr. Staud, the latter speaking of operative treatment. He referred to a suggestion made by Moor, that an attempt be made to remove the effusion with the hypodermic syringe. Having a case, he tried the operation. Although he succeeded in removing a considerable quantity of the subretinal effusion, there was not much improvement, except temporarily. He suggested that the method might be improved by placing a piece of rubber tubing between the needle and the tip of the nozzle, thus making an instrument somewhat similar to that used in the treatment of soft cataract. At least he thought that some form of aspiration might be made applicable in these cases.

Two Cases of Congenital Ectopia Lentis; one Symmetrical, the other Non-Symmetrical.—These cases were reported by Dr. William S. Little, of Philadelphia.

The Employment of Nitrous Oxide as an Anesthetic in Ophthalmic Operations.—Dr. George T. Stevens, of New York, read a paper in which he stated that he had employed it in operations about the nasal duct, iridectomy, cataractotomy, and similar short operations, and believed that it possessed several advantages, such as being less dangerous, unattended with nausea and other manifestations incident to the use of ether, and that it demanded for its administration far less trouble than ether or chloroform. He thought it doubtful if it could be relied upon for cataract operations.

The President had employed it, more or less, during the last ten years, and stated that the oxide had the advantages claimed for it to a certain extent. He had, however, noticed two features: 1. There was apt to be a good deal of rigidity on the part of the patient in some cases. 2. It was apt to be attended with a great deal of venous congestion, which gave rise to considerable hemorrhage in wounds about the eye.

Dr. R. H. Derby, of New York, had employed the nitrous oxide preliminary to prolonged anaesthesia with ether, and with very gratifying results.

Dr. Buller, of Montreal, said that for some time nitrous oxide had been used in the hospitals in London, but with unsatisfactory results. He had resorted to the primary anaesthesia produced by ether with exceedingly gratifying results.

A Contribution to the Operative Treatment of Glaucoma.—Dr. Albert G. Heyl, of Philadelphia, read a paper with this title. After giving the ordinary method of treatment, and detailing the history of a case in which he had resorted to operative treatment, he recommended the following plan as a modification of that which he had employed. It was to ligate the frontal artery and open the supra-orbital artery, allowing a
few ounces of blood to escape, and then close the vessel with a ligature.

Dr. Webster recalled a case in which a California surgeon advocated early ligature of the carotid for glaucoma, performed the operation once, and cured his patient.

The President stated that the natural history of acute glaucoma must be considered before deciding with reference to the influence produced by any modification of the circulation by operation.

Dr. Seely, of Cincinnati, said it should be borne in mind that the influence of the Californian operation was directly the reverse of that suggested by Dr. Heyl.

The Astigmatic Pencils.—Dr. Gustavus Hay, of Boston, read a communication on this subject. It was discussed by Dr. Knapp.

Sarcoma of the Choroid, with Interesting Clinical Features.—Dr. Charles J. Kipp, of Newark, N. J., reported some cases.

Ossification of the Choroid.—Dr. Kipp also read a paper describing a case of very extensive ossification of the choroid occurring in a young man who, when first seen ten years ago, had a chalky cataract, to which the pupil was everywhere adherent. As there were at that time no symptoms of irritation of the eye, and the case was hopeless as far as sight was concerned, no treatment was advised. The boy had been born with the cataract, according to the mother’s statement. Ten years afterward the eye became painful, and presented the appearance of irido-cyclitis. The eye was removed, and, on examination, the oesous plate lined the inner side of the choroid as far as the ciliary processes.

The communication was discussed by Dr. Howk, of Buffalo, who presented a specimen, by the President, by Dr. Middendorf, and by Dr. Webster.

Trituration of the Cortex of Cataract.—Dr. S. Theobald, of Baltimore, read a paper in which he reported two cases of this operation, in connection with preliminary iridectomy, to hasten the development of slowly ripening cataracts. The operation consisted in a kneading, or bruising, of the anterior cortical layers of the lens by pressure on the cornea after iridectomy and while the anterior chamber was still empty, in accordance with the suggestion put forth by Professor Förster, of Breslau. The trituration was done with the angle of the strabisimus-hook, and in the first it was imperfectly performed. In the second case the operation was performed with the smooth end of the Bowman tortoise-shell cataract-spoon, which seemed better adapted to the purpose. In the first the operation was followed by but slight change in the condition of the lens. In the second case, however, a very rapid development of the cataract ensued. In each case there occurred a sufficient amount of iritis to cause slight but persistent adhesions between the iris and lens at the pupillary angle of the cobraion, and in the second case it was found, by oblique examination, a day or two after the operation, that near the cut edges of the iris the pigment layer had been detached from the muscular coat in a manner quite peculiar. That the iris would be more or less bruised as well as the lens, however carefully the trituration was performed, appeared unavoidable, and the risk of exciting inflammation in this manner seemed the chief objection to the procedure. It would appear, however, that Professor Förster had not had serious trouble from this source.

Dr. Greening had performed the operation twice during the last year. In the first he performed a large iridectomy upward, and with the angle of the strabisimus-hook treated the lens in the area of the pupil only. No iritis followed, and the lens became completely opaque within one week. He extracted it three weeks latter with very good results. In the second case he performed iridectomy upward, and again treated the lens only in the area of the pupil, and in four days the lens was completely opaque. He thought there were certain cases in which the operation was indicated, and was attended with great gain.

Dr. Kipp had performed the operation some time ago; the lens became opaque, and four or five days afterward it cleared up again.

Dr. Middendorf thought the operation was indicated, especially in certain cases in which two cataracts were formed. His experience had been equally favorable with Dr. Gruening’s.

Dr. Knapp had performed the operation once, but it did not seem to hasten the ripening of the cataract.

Dr. Wadsworth had operated once, eight years ago. There seemed to be no effect at all so far as ripening of the cataract was concerned. He thought that probably, in some cases, maturity of the cataract might be hastened very much by the method, while in other cases the result would be very slight.

The President had operated eight times, and in seven cases had subsequently performed extraction. In one case marked iritis developed, but did not interfere with the subsequent recovery, and extraction was entirely satisfactory. He hoped to make a communication upon the subject which would embrace the history of all his cases, with remarks.

Dr. Gruening remarked that by the area of the pupil he meant the new pupil, including the coloboma.

The paper was further discussed by Dr. Webster, Dr. Fox, Dr. Dyer, and Dr. Theobald.

Second Day.—Thursday, July 19th.

The society was called to order at 9 a.m. by the President. The treasurer moved that the annual assessment be five dollars. Adopted.

Vaseline Cera, A Convenient Basis for Ointments Intended for Applications to the Eyebrows.—Dr. Theobald, of Baltimore, read a brief paper on this subject, in which he stated that he had been using a cera made of yellow wax and vaseline, with much satisfaction, for several months, both in private and in hospital practice, as a basis for ointments intended for application to the eyebrows. It was made by melting the wax and vaseline together with a gentle heat, and stirring the mixture until it had hardened, combining one part of yellow wax with four of vaseline, which proportion gave the ointment sufficient firmness, except, perhaps, in very hot weather, when the proportion of wax might be increased to one to three. Dr. Theobald also exhibited a specimen of ointment of the yellow oxide of mercury, containing two grains to one drachm of vaseline cera, which, though prepared nearly four months since, and kept with no special care, still retained its bright yellow color, and had undergone no appreciable change. He had been told that cerates prepared with vaseline were in use, but was not aware that attention had been called to the convenience of employing them in the manner suggested.

Blindness from Retinal Thrombus in Consequence of Facial Erysipelas.—Dr. H. Knapp, of New York, read a paper in which he reported a case of this sort. There were on record a certain number of cases of blindness following facial erysipelas. These symptoms varied considerably. Ophthalmoscopic examinations during the first stage of the affection had been lacking. Not long ago he had had the rare opportunity of observing such a case almost, from the beginning to the end. A man, forty years of age, had lived in the tropics, had had syphilis, with secondary and tertiary symptoms, which were aggravated when he came North. On the 20th of March, 1885, while in New York, he had an attack of erysipelas, which began upon the nose, and proceeded to the pharynx, cheeks, and orbits. He was under the care of Dr. Guleke and Dr. Schottky, who kindly
allowed Dr. Knapp to publish the case. The cryspelas progressed, and on March 28th the man was totally blind in both eyes. Reserving a detailed discussion of this case for publication in the "Archives of Ophthalmology," Dr. Knapp restricted himself to the following remarks: 1. The blindness was produced by compression of the central retinal arteries and subsequent thrombosis of the retinal veins, both having been directly observed with the ophthalmoscope one day after the occurrence of the rapid, almost sudden loss of sight. 2. The ophthalmoscopic appearances, observed from beginning to end, showed no neuro-retinitis, but the successive stages of a thrombosis. 3. The decrease of the swelling of the orbital tissue, or the establishment of collateral circulation from the choroid, permitted the return of a limited flow of blood into the retinal arteries, which, however, was impeded by the blocked veins, leading to renewed extravasation, to thrombosis and shrinkage of the arteries, and finally to atrophy of the optic nerve. 4. Perivasculitis played no part, or only an unimportant part, in the pathology. 5. The white segments in the veins and arteries were white thrombi and hypertrophy of the walls of the blood-vessels. 6. Thrombosis being present, the probability that the orbital veins also, but did not, as in other cases, extend to the cerebral sinuses.

The paper was discussed by Dr. Kipp.

**Changes in Refraction Resulting from a Blow.—Dr. W. H. Carmalt, of New Haven, read a paper on this subject. R. A. S., twenty years of age, a student in Yale College, myopic since the age of twelve, consulted him October 28, 1882, stating that while practicing in the gymnasium the day before he had fallen violently forward, striking his right eye upon a bolt projecting from the floor. The blow was sufficiently severe to give rise to disturbance that obliged him to keep quiet for the remainder of the day and evening. At the time of his visit he felt quite well again, except with reference to his eye. Wearing his glasses habitually for all purposes of vision, near or far, he now felt an uncomfortable sensation in looking through his right glass, and could see much better at a distance without it—better, indeed, than he remembered ever to have seen before without glasses, but, for all that, he had a very confused sensation when looking with both eyes, either with or without glasses. Four months afterward he was again consulted, when he found, on ophthalmoscopic examination, that there was no conus at the nerve, nor other evidence of retino-choroidal trouble. By oblique illumination no opacity of the lens was detected. On the following day, at Dr. Carmalt's suggestion, the patient saw Dr. Loring, of New York, in consultation. To summarize the facts of this case, as far as he knew, it seemed established that in a case of myopia of very considerable and nearly equal degrees in the two eyes, one was reduced by the impact of a blow to a condition of astigmatic myopia, which resolved itself finally into a cross astigmatism without any loss of acuteness of vision or range of accommodation. To account for the mechanism of this change, five possibilities presented themselves: 1. A change in the shape of the cornea. 2. A diminution or shortening of the axis of the globe. 3. A displacement or dislocation of the lens backward. 4. A change in the relative position or arrangement of the lenticular fibers. 5. A pre-existing spasm of accommodation, the tonicity of which had been released by the paralytic effect of the blow. Dr. Carmalt concluded, as did also Dr. Loring, change in the length of the eye-ball, dislocation of the lens, and the previous existence of spasm of accommodation. The remaining alternative could not be urged from any knowledge we had of such a condition having been positively determined. It was urged rather as a refuge, all the other explanations having been disproved or not being satisfactory. Was it not possible that a sudden and violent impulse could have shaken and so displaced the denticulate articularations of the lens fibers that they became fastened in a position to correspond to, or cause, the error of refraction indicated?

The paper was discussed by Dr. Knapp, Dr. Noyes, Dr. Seely, Dr. Webster, Dr. Buller, Dr. McKay, and Dr. F. B. Loring.

**A Further Modification in Catalectic Extraction.—Dr. E. E. Bartlett, of Milwaukee, Wis., read a paper with this title. The modification proposed was, to do two preliminary iridectomies in certain difficult cases, one upward and one downward. Two cases were related to illustrate the modification. It was suggested in difficult cases only, as when the eye was very prominent, when the iris did not react to atropine, or attachments had formed between the iris and the capsule, when the other eye had been lost and the least amount of risk should be taken with the other eye, when the patient was very inimical and danger from shock was very great, and when the cataract was maturing very slowly. In such cases this modification gave the patient a better chance of securing a certain amount of sight than the method of doing the whole operation at one time.**

**BLEPHAROPLASTY ACCORDING TO THE ENGLISH METHOD.—Dr. E. Greening, of New York, read a paper on this subject.** A young man sustained an injury of the face by the explosion of a petroleum lamp. As a result of the mishap, the integument of almost the whole forehead, the right temple, the right cheek, and the corresponding half of the nose was changed into dense cicatricial tissue. The upper lid was wholly everted, and its free border attached to the upper orbital margin. To correct the deformity, the lid was detached from the orbit, the neighboring tissues were released, the deep scar was excised, and the free borders of both lids were brought into apposition and united by sutures. The surface of the wound measured forty millimetres in the vertical and fifty-five millimetres in the horizontal direction. In order to cover the defect, a flap was transplanted from the inner surface of the left arm, prepared according to Wolfe's suggestion: i.e., deprived of its subcutaneous cellular and adipose tissue. After careful coaptation of the flap to the edges and the surface of the wound, gold-beater's skin and a bandage were used to maintain it in position. No discoloration, no displacement of the flap ensued; it united firmly with the wound, and the ectropion was corrected. To-day-i.e., nine months after the operation—the flap measured fifteen millimetres in the vertical and thirty millimetres in the horizontal direction. The shrinkage took place during the first four weeks after the operation. The result was very satisfactory, and could not have been obtained by any other method. The paper was discussed by Dr. Wadsworth, Dr. Kipp, and Dr. Andrews.

**Loss of an Eye from Sewer-Gas after Extraction of a Cataract.—Dr. McKay, of Wilmington, reported the case of John H., a German brewer, sixty-one years of age, who was operated upon April 16, 1882, for senile cataract, without an anæsthetic, by Graefe's method of linear extraction. The upward operation was performed satisfactorily, and without accident. He counted fingers immediately after the operation. The eye was covered with absorbent cotton and a light flannel pressure bandage, without the further introduction of a mydriatic. Three days and a half after the operation the bandage became somewhat loosened. The eye was examined, and atropine was introduced. The incision had closed, the cornea was clear, the pupillary field was dark, and vision, tried for a moment, was very encouraging. The patient subsequently showed symptoms of some general disease, evidence of contamination of the atmosphere by sewer-gas was detected, and finally the eye was lost, in consequence, as Dr. McKay believed, of the poisoning of the general system produced by this noxious agent. (To be concluded.)
AMERICAN OTROLOGICAL SOCIETY.

The sixteenth annual meeting was held at the Hotel Knickerbocker, Catskill Mountains, New York, July 17, 1883.

Morning Session.

The society was called to order at 10.30 A.M., by Dr. J. S. Proctor, of Brooklyn, Vice-President, the President, Dr. J. O. Green, of Boston, being absent.

A CASE OF PRIMARY EPITHELIONA OF THE AURICLE; REMOVAL OF THE ENTIRE AURICLE BY THE THEME-CAUTERY.—

Dr. W. W. Seely, of Cincinnati, read a paper on this subject. A man, sixty years of age, was bitten on the ear by a rat six years ago. The wound never healed, but was finally succeeded by the growth which was removed. During the last year the latter had increased in size rapidly, and bled easily on irritation. The original wound was near the summit of the helix. The tumor was removed by means of the thermo-cautery, the hemorrhage being only slight. The entire surface of the stump was covered with a thick layer of powdered boric acid, and the patient was sent home within five weeks with a perfect ear. Dr. Seely regarded primary epithelioma of the auricle as rather rare. Although in this case the thermo-cautery acted well, he thought the knife, with torsion of the arteries, was preferable. He also believed that under the boric-acid treatment the healing period of the wound was reduced at least one half.

Dr. H. Knapp, of New York, thought it rare for epithelioma to arise from a wound.

Dr. Seely thought it generally accepted that epithelioma might be due to injury, and asked what Dr. Knapp would regard as the case in cases of epithelioma of the lip, supposed to be due to using clay pipes, etc.

Dr. Knapp said that the pipe might produce constant irritation of the lip, but he thought that it was not exactly trauma.

Dr. Seely regarded it as the perfection of trauma. The special point of interest in his specimen was its occurrence in a region where neither traumatism nor epithelioma was likely to develop.

INVITED GUESTS.—Dr. Strawbridge, of Philadelphia, introduced Dr. Andrews and Dr. L. Webster Fox, of Philadelphia, and they were invited to attend the meeting.

ON THE INTERMITTENT PERCEPTION OF SOUND, AS CONVEYED THROUGH THE AIR AND CRANIAL BONES, WITH A BRIEF SUMMARY OF THE RESULTS OF TREATMENT IN CHRONIC AURAL AFFECTIONS WITH IMPAIRED HEARING.—A paper with this title, by Dr. J. A. Andrews, of Clifton, N. J., was read by title, and referred to the Committee on Publication.

THE RECOGNITION OF BRAIN COMPLICATION IN AURAL AFFECTIONS.—Dr. Andrews then read a paper on this subject, which contained the clinical histories, together with the records of autopsies, of five cases of brain disease secondary to ear disease under his own observation. Special attention had been directed to the condition of the eye, and in all his cases the ophthalmoscope had revealed either papillitis or a hazy, slightly edematous appearance of the optic-nerve disc—very valuable corroborative evidence of a cerebral complication, especially where the other symptoms were obscure. Dr. Andrews believed that most ophthalmologists would endorse the statement that optic neuritis and vision of 20/200 were not incompatible. The existence of a cloudy disc in cases of ear disease should excite suspicion, and he believed that the condition of the optic-nerve disc furnished evidence which had not received the attention it deserved. In the majority of cases reported, the condition of the eye was referred to only incidentally. In one case there was a cerebral abscess, which Dr. Andrews thought had undoubtedly existed for twelve years. It was also a significant fact, in connection with cerebral localization, that cerebral abscess secondary to ear disease was usually in the medullary substance, and seldom in the cortex. The significance of special symptoms, as vertigo, vomiting, headache (more continuous and less paroxysmal than with brain tumor), edema over the mastoid, etc., were considered. Fever was very often absent. The sight was most affected on the side of the brain lesion.

Dr. Kipp, of Newark, N. J., had published a number of cases in which eye symptoms were present, and also stated that Dr. Knapp had since published several. Dr. Kipp's published cases preceded those reported by Zaufel.

Dr. Seely, of Cincinnati, had examined the eyes with the ophthalmoscope in cases of suppurative middle-ear disease, but so far with negative results, and he thought that definite results had not yet been obtained in that direction.

Dr. Strawbridge, of Philadelphia, said that, after Dr. Roos directed attention to this subject at Newport, he had examined the eyes of all his patients suffering from suppurative middle-ear disease, but without satisfactory results. He had also made analyses of the urine, and had frequently found large quantities of albumin present when brain complication existed.

Dr. Kipp said he had continued his observations, and had found, in cases in which meningitis was present, that there was almost always a change in the fundus, something like optic neuritis, between the 10th and 15th day after injury. The change had been stated to take place only in cases in which cerebral complications existed.

Dr. Andrews said he alluded only to those cases in which brain complications were suspected. In all his cases he had examined the urine with negative results. Dr. Seely did not doubt that in cases of actual brain complication more or less evidence would be found in the fundus oculi, but in such cases the ocular symptoms were less important than in those where the question of diagnosis was doubtful, or in the cases of suppurative middle ear disease as they were generally seen. He had observed two or three cases in which there were marked changes in the eye on the side of the affected ear, but these passed away, and he was left in doubt whether there was very much affection of the brain.

Dr. Kipp believed that optic neuritis might exist with ear trouble, and pass away as the brain affection ceased.

Dr. Bartlett, of Milwaukee, regarded ophthalmoscopic examination as very valuable in the acute stage of meningitis. A slight cloudiness of the fundus indicated that degeneration of the parts of the brain involved had not yet taken place, but, when degeneration had begun, the appearances in the eye disappeared, sight improved, etc. For the alienist, therefore, such examinations were important.

Dr. Samuel Sexton, of New York, asked if the ophthalmoscope had been found of service as a means of diagnosis where other symptoms had not been prominent, especially in fatal cases of meningitis and cerebral abscess.

Dr. Kipp had examined many hundreds of cases of otitis media, and had not found any with eye symptoms in which there were not other signs of brain complication.

Dr. Knapp thought that the ophthalmoscope sometimes gave most valuable evidence, more so than could be obtained from the patient. In one of his published cases the cedema was very slight, while the pain and other subjective symptoms were marked, and had existed for some time; but, as soon as the symptoms became severe and pointed toward a fatal termination, the optic disc was swollen, first upon one side and then upon the other. The recession of the ocular appearances had guided him with regard to stopping the opening made in the mastoid to close, and in just these cases ophthalmoscopic examination had been of great value. When the optic disc became
normal, and the discharge from the mastoid was slight, the
opening could with safety be left to close, and he thought he
had in this way abridged the period of healing materially.

The paper was further discussed by Dr. Sexton, Dr. Straw-
bridge, Dr. Seely, Dr. Knapp, and Dr. Kipp.

External and Internal Inflammation of the Mastoid,
with Cases.—This paper, by Dr. Sexton, was read by title, and
referred to the Committee on Publication.

Case of Acute Desquamative Inflammation of the Ex-
ternal Auditory Canal; Acute Otitis Media; Mastoid-
itis; and Chronic Meningitis; Recovery.—The case was re-
ported by Dr. Read J. McKay, of Wilmington, Del.

Case of Mastoid Disease; Artificial Perforation of the
Bone; Temporary Relief; Death from Pyemia.—Dr. C. H.
Burnett, of Philadelphia, read a paper giving an account of a

case of chronic purulent inflammation of the middle ear induc-
ing general increased vascularity of the pyramidal part of the
temporal bone, and hyperostosis of the outer wall of the mas-
toid groove without necrosis. The mastoid cavity became filled
with cheesy débris, and this, furnishing a pyreemic source of em-
bolism, was followed by embolism of a chronic form, as shown,
first, by abscess in the lung, and then by infiltration of the liver
with abscesses. Dr. Burnett thought trephining of the bone
was comparatively free from danger, and that it afforded the
one slim chance of escape from death in cases of true mastoid
disease, which must necessarily furnish an embolic source for
the production of inflammation, purulent and cheesy débris be-
ing pent up in the mastoid cavity. In such cases there were
the chances of death from embolism, while there were none
from the operation. In the case reported, the patient survived
the mastoid operation two weeks, and the wound was nearly
healed, when the man was seized with a chill and rapidly sank
from embolic hepatitis.

These papers gave rise to an extended discussion on trephin-
ing of the mastoid when involved in middle-ear disease.

Dr. Strawbridge had never performed the operation upon
the living subject. He had seen about five thousand cases of
purulent middle-ear disease during the last twelve years, and
had not had occasion to trephine a single mastoid. Nor had he
but a single death, which occurred in a child six months old, that
died a few hours after he first saw the case. In studying the
subject he had been struck with the very small percentage of
cases in which pus was found after the bone had been trephined.
He would ask if the absence of pus was not evidence that the
operation had not been indicated.

Dr. Knapp said that the mastoid had been trephined with
marked benefit in quite a number of cases in which pus had not
been found. Such cases had been reported by Hartmann, and
also by himself. His firm conviction was that, when chronic
middle-ear disease, even without suppuration or perforation,
was attended with more or less obstinate constant pain, which
had its origin in the mastoid process, and radiated from there
over the corresponding half of the face and side of the head,
trephining the mastoid was indicated.

Dr. Sexton had not seen so many cases requiring opening of
the mastoid as had been mentioned by several authorities, as
Buck, Schwartz, and others, and only a very few in which he had
thought the operation might be necessary, without some further
evidence than the pain in the mastoid. He thought there might
be danger in attributing too much importance to pain as a symp-
tom in these cases. With regard to operative procedure, it had
happened to him to be able to liberate the pent-up secretion
through the posterior wall of the auditory canal, and he thought
that in a large majority of cases pointing took place in that
direction, rather than toward the brain. He regarded early
constitutional treatment as especially important, particularly by
the use of sulphate of calcium, of which he seldom, of late,
had given more than one tenth of a grain at a dose, and fre-
quently a much smaller quantity, repeating it perhaps every
one or two hours; of course, the liberation of pus when formed
was a well-established surgical procedure, and must not be
omitted.

Dr. Throbaud, of Baltimore, said that his experience had
been similar to Dr. Strawbridge’s, and, so far, he had opened the
mastoid only upon the dead subject. He did not believe that
the indications for performing the operation occurred very fre-
cently. Early constitutional and local treatment he thought
would have cured most of the patients in whom the mastoid
had been opened. He regarded leeches as exceedingly service-
able.

Dr. Kipp thought that the operation was essentially harm-
less, and believed it to be better to operate and not find pus
than to allow the case to go on to the death of the patient with
pus in the mastoid cells, where by an operation it could have
been removed. He maintained that there were cases in which
suppuration occurred in the mastoid irrespective of constitutional
treatment, and he had seen them.

Dr. Bartlett had not found it necessary to trephine the
mastoid. He had relied on poultices, applied every half hour,
as hot as the patient could bear, and had seen several cases in
which pointing took place within twelve hours. The pus was
then let out with an ordinary scalpel, cutting through into the
mastoid.

Dr. Strawbridge corroborated Dr. Bartlett’s experience
concerning the value of poultices.

Dr. C. H. Burnett thought that poulticing could not pro-
duce much effect upon the mastoid cells if the external wall of
the process was intact.

Dr. Jones, of Chicago, thought no general rule could be laid
down; but that each case must be treated independently accord-
ing to the conditions present.

Dr. E. E. Holt, of Portland, Me., had had forty cases of mas-
toid disease in two thousand cases of ear disease of all kinds.
He had not perforated the mastoid, and had had but three
deaths, all of which could be explained without reference to the
condition of the mastoid. He had used leeches more than any
other measure, unless it was incision.

The subject was further discussed by Dr. Sexton, Dr. Bur-
nett, and Dr. Knapp.

Teratoid Tumors of Both Achilles, Having a Clinical
History of Recurrent Fibroids.—Dr. Holt read a paper in
which he reported the case of a woman twenty-nine years of
age, of light complexion, and usually of good health. These
morbid growths were of unusual interest in the following re-
spects: 1. They promptly followed perforation of the lobes and
wearing of gold ear-rings. 2. They had repeatedly occurred
during a period extending over twenty years. 3. They had
undergone a remarkable change in structure. In proof of this
latter assertion, a portion of a letter was read from Dr. John H.
Bripley, of New York, who had removed the tumors several
times, and who stated that they contained nothing but dense
interlacing fibrous tissue. An exhaustive examination made of
the recent growth by Dr. Edward Preble, of Portland, however,
showed that they contained germinal matter in abundance, with
the following tissues: Myxomatous and adenoid tissue, giant
cells, fibro-plastic tissue, loose areolar tissue with infiltrated
fat, innumerable elastic fibers, fine and coarse fibrous tissue,
lysinie, reticular, and fibro-cartilage, smooth muscle, fragments
of large blood-vessels, well-developed skin with corium, papil-
le, retic mucous, and epidermis, hair follicles, hair and sebaceous
glands, together with certain unclassified struc-
tures.
Evening Session.

The society was called to order by the Vice-President, Dr. J. S. Frout.

Invited Guests.—Dr. Murdock, of Baltimore; Dr. H. W. Williams, of Boston, and Dr. R. II. Johnson, of Philadelphia, were introduced, and invited to remain in attendance.

Amendment to the By-Laws.—Dr. John Green, Chairman of the Committee on Membership, offered the following: The first by-law, relating to the election of members, shall be amended so as to read, "after the report of this committee has been received and at the same meeting;" etc.

Chronic Inflammation of the Mastoid Cells without Perforation of the Membrane Temporal.—Dr. Sexton presented a patient who had formerly been under his care with this affection. The case had been complicated with otosmia. This case opened the discussion again on the question of trephining the mastoid, which was participated in by Dr. Gruening, of New York, who argued very strongly in favor of the operation, Dr. Kipp, Dr. Bartlett, Dr. Theobald, Dr. Burnett, Dr. Sexton, and Dr. Webster.

Observations on the Hearing Power in Different Conditions.—Dr. Holt read a paper in which he gave the results of examinations of four series of persons: 1. Twenty-four patients with chronic non-suppurative otitis media from private practice; 2. twenty-four machinists; 3. twenty-four boiler-makers; and, 4. twenty-four persons with normal ears. The hearing power was tested by the voice, the tick of a stop-watch, the tuning-fork, and Koenig's rods, and the average age, ratio of bone conduction to aural conduction, and the audibility of Koenig's rods in these series of tests were compared with each other and with the normal ear. It was ascertained that the ratio between bone and aural conduction diminished in corresponding degree to that of the hearing power for the voice, and that the average audibility for the upper limit of Koenig's rods was quite equal to the average normal of 40,000 V. S., as determined by Dr. Blake. Therefore, the conclusion was drawn that the loss of hearing in the machinists and boiler-makers was due much more to a defect in the conducting than in the perceptive part of the organ of hearing, for the following reasons: 1. Because of a history or present condition of catarrh of the middle ear and naso-pharynx. 2. Because the tuning-fork, when placed vibrating between the central teeth, was heard louder and longer in the non-affected ear, and the sound of it was invariably increased by pressing on the tragus and closing the meatus. 3. Because, had there been any considerable disease of the labyrinth, they would not have responded so nearly to the normal average audibility for the upper limit of Koenig's rods, since such an astute observer as Dr. Blake, who had made extensive use of them, had never had a case of labyrinth disease without a "marked loss of hearing for the Koenig rods." In regard to hearing in a noise, several of the three series of persons stated that they could hear better in a noise. These were carefully tested in a quiet place and then in a noise, and in every instance there was no improvement of hearing in a noise; on the other hand, when the voice was used at the same time, it was not heard quite so well in the noise as in a quiet place.

The Association of Aural Disease with Simple Sparkling Synchisis of the Vitreous Humor.—Dr. Kipp read a paper in which he stated that, in six of the seven cases of synchisis of which he had records, aural symptoms were present. In the seventh case it was not known whether or not ear trouble existed. In five of the cases the synchisis scintillans existed in only one eye, and in two of them the ear of the same side only was affected. In the other three both ears were diseased. In four of the cases the ear involved both the middle ear and the nervous apparatus. In one case there was chronic suppuration of the middle ear, which had been preceded for years by impairment of hearing without otosmia. In the sixth case there had been absolute deafness of one ear since infancy. Otologic literature contained no record of similar cases, and the author thought that the association of the two affections in his cases might have been merely accidental. They were related with a view of inducing others to examine their patients with synchisis for aural trouble, and thus settle this question.

The paper was discussed by Dr. W. S. Little, of Philadelphia, and Dr. Webster, of New York.

Anomalous Sebaceous Gland in Immediate Proximity to the Auricle.—This was the title of a paper by Dr. Charles A. Tood, of St. Louis, which was read by title and referred to the Committee on Publication.

The Significance of the Transmission of Sound to the Ear through the Tissues in Acute Disease.—Dr. Sexton read a paper with this title. It was discussed by Dr. Burnett, Dr. Holt, Dr. Andrews, and Dr. Kipp.

Dr. Sexton then exhibited fourteen photographs of various forms of ear affections; also two ear syringes, together with a hooked curette for removing foreign bodies from the ear where it was necessary to use a forceps.

Obstructive Purely Desquamative Otitis Media.—Dr. Knapp read a paper in which he reported a case that was finally cured. He laid special stress upon the fact that, where there was desquamative otitis media, palliative treatment produced only temporary benefit, and that to effect a cure it must be converted into an acute case, a condition that could be cured. The case was a new confirmation of views which he had expressed before the society two years before concerning the treatment of granulations and polypi. He had then stated that in cases of diffuse granulations and broad sessile polypoid excrences he abstained from destroying them by cauteries or sharp instruments, because these procedures were likely to destroy essential parts of the drum cavity, and terminate in replacing the membrane by cicatricial tissue, thus bringing about an unpleasant condition known as sclerosis. The only reasonable plan was to change the condition of the parts, and this he accomplished by instillations of warm water, and by keeping the parts moist with cotton soaked in glycerin.

A somewhat prolonged discussion followed on the question whether or not a new drum-head was ever actually formed after being destroyed by disease.

The society then went into executive session, and afterward adjourned, to meet in 1884.

New Members.—Dr. W. S. Little, of Philadelphia, Dr. B. E. Fryer, U. S. Army, Fort Leavenworth, Kansas, Dr. R. O. Born, of New York, and Dr. J. A. Lippincott, of Pittsburgh, Pa., were elected to membership.

Officers for the ensuing year were then elected. (The list was given in our last issue.)

COLLEGE OF PHYSICIANS OF PHILADELPHIA.

Meeting of March 7, 1883.

The History of a Case of Abdominal Cystic Tumor, where Seven Years after Removal of the Tumor by Laparotomy a Second Operation was Demanded: Tapping through the Vagina Resorted to, with Consequent Death of the Patient.—Dr. Walter F. Atlee read the following paper:

Bene facit qui ex erroribus avis spectum alia probat.

In June, 1875, I removed, by laparotomy, in the St. Luke Hospital, Bethlehem, a multilocular cyst from Mrs. DeM. The history of the case was given by Dr. Stout to the Board of
Trustees, and published in their second "Annual Report." The whole mass removed at the operation weighed 754 pounds. The lobes and lobules composing it were made up of cysts containing fluids of different densities, colors, and other physical properties. The pedicle appeared to arise from the rectum; at all events, the cyst wall was separated from everything else, except the front of that intestine, and the only ligature used was there applied. The whole vascular supply was derived from meso-rectal vessels. Of course, the clamp could not be used. As always, in sewing up the incision in the abdominal walls, I carefully included the peritoneum in the sutures, as in this way adhesions of intestine and omentum, with the consequent discomfort and constipation suffered by the patient, are never observed, and, moreover, in case a second ovariotomy should have to be performed, the operation could be performed with much more ease and safety.

This patient recovered from the operation, though somewhat slowly, owing to delay and difficulty in removing the ligation, which was left hanging out of the external wound, and not cut short and left inside the abdomen, as is now generally practiced. She remained in perfect health for seven years, but in the summer of 1859 came to my office complaining of considerable discomfort in the pelvis, where I detected, by the touch, the presence of a swelling, caused by a thick, viscid fluid; in other words, there was plainly a second tumor formed there. This continued to enlarge, and in the month of January the suffering it occasioned was so immediately threatening to the patient's life that it was necessary to act. Great efforts were made to push the tumor out of the pelvis, but this was not to be accomplished. It remained to operate as before, and remove the mass by laparotomy, or to give relief by emptying the cyst by tapping through the vagina. The latter procedure was preferred, and about three pints of a very thick, dark-colored fluid were drawn off by a Thompson trocar. There was no difficulty about the operation, nor was it attended by any particular pain, nor was there any hemorrhage. The next day the patient felt herself completely relieved, but after that her pulse became quickened, and a general febrile condition, unpreceded by chill, succeeded. There was evident tenderness on pressure over the lower part of the abdomen, but no severe pain independent of this pressure. The stomach became so irritable as to reject everything swallowed. Death took place on the eighth day, under the marked symptoms of depression which accompany pyrexia. It was a death, most plainly, from cyst inflammation.

Notwithstanding the great number of cases of operation for ovarian disease reported nowadays in journals more or less medical, this case is really one deserving of record, and one of true and special interest to the pathologist and to the surgeon.

In removing the large mass in the first operation, in this case, it was noticed that no pedicle was found. It was separable by the fingers everywhere except from the front of the rectum, where it was necessary to apply a ligature and divide the attachment with scissors. The ovaries, as we all know, are situated in the posterior fold of the broad ligaments, on the sides of the highest part of the uterums, behind the Fallopian tubes and the round ligaments, which separate them from the bladder, and in front of the rectum, from which they are commonly separated by the lowest circumvolutions of the ileum. By a rounded cord, the ligament of the ovary, they are attached internally to the womb, and externally by two folds of the peritoneum to the sides of the pelvis.

As the ovary, in its normal condition, is not pediculated, at first, of course, a diseased ovary has no true pedicle. As it becomes larger, this pedicle is formed from changes in its normal connections with the adjacent womb; it consists of the Fallopian tube often much elongated, the broad ligament often considerably thickened, the utero-ovarian ligament occasionally hypertrophied to a large fibroid stem, the round ligament, and enlarged blood-vessels. If the tumor rises out of the pelvis the pedicle will be longer, and if bound down in the pelvis from early adhesions it will be shorter.

In some cases, however, and they are by no means rare ones, when cystic tumors are removed from the abdominal cavity, no such pedicle as the one just described is met with. In the case whose history I have been relating it was said that there was no distinct pedicle, and that the whole vascular supply came from the vessels of the meso-rectum. It may naturally be supposed that this was owing to the way in which the diseased mass may have been separated from its surroundings, and I therefore call attention to the fact that the same thing has occurred in the practice of an operator such as Spencer Wells. In his "Diseases of the Ovaries," in relating Case CX, he says that he found no pedicle, and that the tumor derived its vascular supply from the omental and mesenteric vessels.

It seems to me most reasonable to look upon some of the abdominal tumors having these connections, not as enlarged and diseased ovaries, but as changed ovules, which have failed to enter the Fallopian tubes, have slipped in the interstices of the neighboring organs, become attached, received blood, and grown. In women, when the Fallopian tube has become adherent, in place of floating loosely, the ovule is not grasped as it leaves the ovary, and then it is not rare to see, fifteen, twenty, or even more small cysts, some as large as a pea, on the parts immediately in contact with the ovary. (See Sappey, vol. iii, p. 644.)

If one of these misplaced ovules was attached to a spot where plenty of blood was supplied, a large cyst could be formed, having no distinct pedicle, as in the case before us. As is seen in cases of extra-uterine fixation, a well-made child can be formed in this way from a fecundated ovule, and we may suppose that from an unfecundated one a monstrous polycystic growth should form.

Although out of the way, I wish to mention here that the only two cases in which I have been consulted on account of a return of abdominal cystic tumors were where there was no pedicle, and where the chief vascular supply came from the vessels in front of the rectum. One case is the one now under consideration, and the other is the one published in the "American Journal of the Medical Sciences" for January, 1889; on account of the bladder having been opened during the operation.

My reason for reporting this case, however, is not to advance any particular views in regard to the pathology of certain polycystic tumors of the abdominal cavity, but in order to speak of the mistake made in the treatment. In the words of one who has done as much as any other to advance our knowledge of the treatment of abdominal tumors, "Mistakes teach most valuable lessons, and, when discovered, are not likely to be repeated. Hence, in medicine, they should be recorded for the benefit of science and of humanity." ("General and Differential Diagnosis of Ovarian Tumors," by Washington L. Atlee, in preface.)

When this case presented itself it was necessary to act; a speedy and most painful death was inevitable unless relief were afforded. It remained to choose between the removal of the cyst and the emptying of its contents by tapping through the vagina, the only way practicable of introducing a trocar. On account of the operation previously performed, and the impossibility of moving the mass in the pelvis, its removal was not attempted. A previous operation is not necessarily an objection; Dr. Washington L. Atlee records two cases where a second operation was performed, and in both successfully.

Spencer
Dr. Charles West, whose opinions have for me, at least, extraordinary importance, greater, indeed, on such a point than those of any other man, says that there is no doubt but that inflammation attacking parts within the pelvic cavity is less apt to extend to the peritoneum than when it attacks an abdominal organ; of which rule pelvic cellulitis and inflammation of parts within the folds of the broad ligaments are apt illustrations. It is equally incontestable that pelvic peritonitis is less apt to become generalized than is similar mischief originating in the abdomen. Cyst inflammation is so dangerous, however, that it is doubtful if vaginal tapping may be employed, even when the cyst is simple. Its dangers are incalculable. The dangers of ovariotomy are far less. Except when a cyst is impacted in the pelvic cavity, he does not recommend tapping per vagina. (West, "Lectures on Diseases of Women," 1879.)

Our best authorities, therefore, teach us that the tapping of polycystic tumors at least must be avoided; that the removal of the cyst is to be practiced in preference; that when impacted in the pelvis, so that it interferes with the performance of functions absolutely necessary to life, tapping, to which we must have recourse, is particularly dangerous, owing to the frequency of cystic inflammation, and consequent death from septicaemia. In my case I thought to avoid this by taking precautions to hinder the entrance of air into the cyst, but it took place notwithstanding, and the death of the patient was occasioned by it in eight days.

If, unhappily, I should ever again be called upon to try to relieve a similar case, I should act differently, and, not relying upon any means to prevent the setting up of cystic inflammation, do more to establish a free outlet for the noxious products by which the system is poisoned, and do everything in my power to prevent their formation by topical applications to the secreting surfaces of the cyst.

Dr. Noeggerath ("Ovariocontes des Vaginales," "American Journal of Obstetrics," May, 1869), by pursuing this course, had such good results as to declare himself confident that, where a simple or compound cyst could be attacked through the posterior vaginal cul-de-sac, this operation would take the place of laparotomy. The plan he prefers is to make first a transverse incision, about an inch long, behind the cervix uteri and through the roof of the vagina up to the cyst. This, coming into view, is then evacuated by a free incision, and, finally, the edges of the two incisions are stitched together by five or six silver sutures. The cyst, thus left free and permanently open, is daily washed out with antiseptic injections until it finally contracts, and ceases to afford any secretion. Although, at the present time, it is not likely that in ordinary cases any one would choose to perform this operation in preference to that of the removal of the cyst, yet all experience shows that, when the cyst is so firmly fixed in the pelvis as not to be removable, it diminishes in a marked degree the great danger necessarily incurred by tapping through the vagina—that of poisoning of the system by the absorption of the putrid products of cystic inflammation.

I feel certain myself that I made a sad mistake in not operating in this way, and report this case as a warning to others—Bene facit qui ex erroribus altorum sibi exemplum sumit. [After the reading of the preceding paper:]

Dr. William Goodell said that he did not think the attachment of the tumor to the rectum was so unique as the return of the tumor. He had on several occasions removed tumors without being able to find the true pedicle, on account of the many adhesions. He could not agree with Dr. Atlee with regard to the origin of the cyst; he did not think it could have come from a wandering ovum, since, in that case, it would have been monocytic.
He regarded tapping per vaginam as hazardous, for the reasons given by the late Dr. Peaslee, first, on account of the danger of wounding blood-vessels, and, second, on account of the danger arising from the entrance of air into the cyst. He did not understand why the air could enter the cyst so readily after tapping per vaginam. When he performed tapping by this method he employed the aspirator. Returning to the question of the apparent attachment of the pedicle to the rectum, in the case reported, he said that it was quite common not to find a pedicle in some forms of intra-ligamentous cyst, because they had to be enucleated, and referred to the statements of Lawson Tait with regard to this difficulty of determining the origin of the tumor. He desired to call attention to the pathological characters of the recurrent growths, and stated that, according to his observation, they were always malignant, and that they recurred in the stump of the pedicle, or, as he had seen, at the site of the adhesions. He alluded to a case which occurred in his own practice, and to one related to him by Dr. Bantock, of London, which confirmed the statements made.

He asked Dr. Atlee whether he could explain why the air entered so readily into cysts after tapping per vaginam.

Dr. Atlee, in reply, said that he had seen no reason given, but thought it was owing to the difficulty in closing the wound made in the tapping.

Dr. R. P. Harris remarked that perhaps he could throw some light upon the cause of this admission of air, from what he had observed in a case of removal of haemorrhoids. Some years ago, soon after the introduction of the bistoury of Chassaignac, he called in the late Dr. Joseph Pancoast, who had obtained the instrument, to make use of it in removing a mass of haemorrhoids from the rectum of a very anemic man, rendered such by repeated hemorrhages after division. After the operation, to prevent, as he stated, the suction power of the diaphragm upon the rectum, endangering secondary hemorrhage, Dr. Pancoast introduced into the anus a small box-wood tube. The effect of this was soon demonstrated: a large drop of serous fluid descended the tube and stopped at its exit; when the diaphragm arose in expiration, the drop was drawn up the tube, and, when it descended in inspiration, it came down again, thus showing the pumping effect of the diaphragm upon the pelvic contents. Let this open tube become an opened cyst with thinned walls, and we have air pumped into the cyst, as it was into the rectum of our patient.

Dr. J. Ewing Means asked Dr. Atlee whether a post-mortem examination had been made. He thought the observations of Dr. Goodell with regard to the difficulty of finding the true pedicle in tumors with many adhesions, and to the pathological character of the recurring tumor in these cases, to be correct, as such had been his experience in instances of which he had had personal knowledge. With regard to the entrance of air into the cyst, when tapping was performed per vaginam, he thought the explanations of Dr. Atlee and Dr. Harris were correct. A cyst firmly impacted in the pelvic cavity was separated from the vaginal tube by a comparatively thin septum, differing greatly in its anatomical characters from the abdominal wall. The opening made by the trocar in this septum and in the cyst wall attached to it by adhesions did not close perfectly, and the air drawn up into the vaginal tube passed readily into the collapsed cyst.

Dr. Atlee, in reply to Dr. Mears, stated that no post-mortem examination had been made.

NEW YORK SOCIETY OF GERMAN PHYSICIANS.

A STATED meeting was held June 23, 1882, Dr. A. Jacoby in the chair.

CHANGE OF THE EYKILD (?).—Dr. J. P. Oberndorfer presented a little girl who contracted diphtheria of the pharynx four weeks previously. A few days ago three papules were noticed on the upper lid of the right eye. These gradually became confluent, forming a hard nodule, which subsequently opened, evacuating a considerable quantity of pus. The whole of the lid had become indurated, and the submaxillary glands of the same side were enlarged, so that the speaker had no doubt that this was a case of primary lesion of syphilis. After a careful examination of the case, Dr. Gruening was prepared to corroborate the diagnosis.

Dr. Jacoby was of the opinion that the lesion under consideration was a simple ulcer, that had possibly been malntreated; the discharge of a by no means small quantity of pus from the indurated swelling certainly did not point to syphilis.

Dr. B. Schaarblau coincided in this view, and thought that the ulcer, originally simple, might have been modified in character by the influence of diphtheritic virus.

Dr. H. C. Klotz did not regard the induration, upon which so much stress had been laid, as pathognomonic, since every inflammation of the lid imparted a hard sensation to the touch.

Dr. A. G. Geistner recollected having seen a very similar case some five years ago; a careful investigation proved the induration of the lid to be a vaccine pustule.

Dr. Oberndorfer called attention to the fact that the ulcer was hard, circumscribed, and indolent; the three small papules were likewise hard; a simple ulcer or a furuncle would usually be quite painful. He proposed to observe the case closely, and treat it locally; he would report further developments at the next meeting.

Dr. E. Gruening remarked that swelling of the glands was a rare concomitant of affections of the lid.

Dr. H. S. Oppenheimer recalled a case of phlegmon of the upper lid with swelling of the glands in front of the ear.

Dr. Gruening had not observed this to be the case, except when the temporal region was also involved.

GRANDE HYSTÉRIE IN A MAN.—Dr. Seibert presented a young man who had afforded him an opportunity to study the various characteristic manifestations of so-called "grande hystérie." The patient was twenty years of age, married eight months, and had no syphilitic taint; he had been under treatment for "cramps" at Charity Hospital for four months. He had been quite well for a year. On the 4th of June he had experienced some unusual annoyance, and on the following day he had experienced his first attack. The speaker had been present at several of these attacks; the head was drawn back, the eyes were open, staring directly upward, the hands supinated and clenched. The patient would jerk his body alternately into a condition of opisthotonos and relaxation, with great violence. On the 7th of June he suddenly became deaf and dumb, and was unable to swallow. The tongue, hyoid bone, and larynx were found to be in a state of spasmodic rigidity, due to the contraction of the several muscles controlling these organs. The sensorium was not affected; several hours later he had regained the power of speech, hearing, and deglutition. This performance was repeated several times. By pressure on the seventh cervical vertebra, Dr. Seibert could, at will, produce general clonic and tonic convulsions.

Dr. J. Rudisch remarked that "grande hystérie" was but rarely observed in men. In several cases it had been recorded that the seizures could be produced by pressure on the testicles.

Dr. Oppenheimer had seen a very similar case, and had on two occasions succeeded in cutting short the attack by pressure of the testicles.

DOUBLE HALLUX VALGIS.—Dr. Geistner presented a man who had had double hallux valgus, and on whom he had oper-
ated with success. The pathological condition represented by this painful affection could be defined as consisting in an exos-
tosis of the head of the first metatarsal bone, with inflammatory
thickening of the bursal sac and communication of the latter
with the metatarsal-phalangeal articulation. The operative pro-
cedure consisted in the removal of the head of the bone and
drainage of the wound. Twelve days after the operation the
patient was able to be about in slippers; the functional result
was excellent. In walking, the head of the second metatarsal
bone was substituted for that removed. The diminution of the
size of the sole was too inconsiderable to interfere with locomotion.
Dr. Gerster had performed this operation ten times on
seven patients.

Dr. SchiARLAC had performed the identical operation ten years
ago. The method had originated with Hunter, and Dr. Frank
Hamilton had reported it in the "Medical Record."

Dr. OBERNDORFER thought that traction on the extensor hal-
luci would produce a relapse of the trouble. Dr. Gerster had
not witnessed that result.

EXSUDATIVE MENGIS.—Dr. H. J. Garrigues presented a
specimen of this affection. [This case was described by Dr.
Garrigues in vol. xxxvi of the "New York Medical Journal,"
p. 587.]

Dr. SchiARLAC recollected having met with a similar case.
Klob had described the disease in his work on the "Pathologi-
cal Anatomy of the Female Sexual Organs," under the name of
"putrescentia uteri," and Virchow had characterized it as "in-
ternal malignant perureral erysipelas."

Dr. Gerster and Dr. KUCHER remarked that they had also
observed cases of the kind.

CONGENITAL OBSTRUCTION OF THE AORTIC OPENING.—Dr.
MATR presented a heart with congenital obliteration of the
aortic opening, removed from the body of a child four weeks of
age. From the date of birth the labored respiration had attract-
ed attention; in the third week the child turned blue. No radial
pulse could be detected for thirty-six hours before the child's
death, but pulsation was noticed in the dorsalis pedis artery,
and a bellows murmur was heard at the level of the third rib.
On inspecting the preparation, the right side of the heart was
found to be very much dilated; the ductus arteriosus and the
foreamen ovale were patent, the aorta ending in a cal-deseño.

Dr. JACOBI remarked that this form of malformation of the
heart was not rare. RauChfuss had described it, and Gebhard
had collected some thirty cases of congenital occlusion of the
aorta in his recent work.

A. G. GERSTER, M.D.,
Secretary.

A stated meeting was held September 22, 1882, Dr. W. T.
Kudlich in the chair.

PAPILLO-SARCOMA OF THE PENTIS; ENucleATION AND PLASTIC
REPAIR.—Dr. A. G. GERSTER presented a case of marked devel-
opment of papilloma of the penis. The patient was a man
thirty-two years of age, whose prepuce was very redundant
and had, in consequence, become the seat of a crop of venereal
warts. Rather irritable treatment at the hands of the patient's
former medical attendant had caused the growth to spread very
rapidly, and it had involved not only the entire prepuce, the
larger portion of the surface of the glans, and the sheath of the
penis, but even invaded the corpora cavernosa, the process also
assuming a sarcomatous character. The crest of the prepuce
showed an excoriation of the size of a dime, from the base of
which sprang red, cauliflower-like fungosities which bled very
readily. The more superficial portions of the neoplasm did not
differ from ordinary papillomas in nature, but the deeper struc-
tures, forming the base, were anemic, tough, and fibro-sarcoma-
tous in structure, and adherent to the subjacent tissues. Amputa-
tion of the penis had originally been decided upon, with the
consent of the patient, but the speaker had finally concluded to
attempt an enucleation of the diseased structures, a proceeding
that was readily accomplished with the aid of the fingers and
scissors, but not without considerable hemorrhage from the
walls and the corpora cavernosa. The latter had forfeited quite
a portion of their fibrous investment. The resulting wound
surfaces were then freely seared with Paquetlin's thermo-cantery,
which also promptly controlled the hemorrhage, and the de-
nuded penis was supplied with a new investment from the in-
tegument of the scrotum, which had been slit, along the raphé,
as far as its most dependent point. The anterior margins of the
scrotal flaps were secured to the stump of the glans, the poste-
rior being brought together along the dorsum of the penis; in
all, twenty-five catgut sutures had been applied. Primary union
was obtained at all points, excepting to the extent of about 14
em. on the dorsum of the penis, where a small tract of the
fibrous envelope of the right corpus cavernosum had sloughed.

The operator had preserved its erectile capacity, although it had
diminished in circumference through the loss of a considerable
portion of the corpora cavernosa, and its line of projection was equally
satisfactory. Dr. Gerster proposed to complete the operation,
and to restore to the organ its natural shape, by making a cross
incision into the fold of scrotum depending from the body of
the penis, and then uniting the lips by vertical suture.

ABR30 OF DEVELOPMENT, GIANT GROWTH, AND LIPATOMATOSIS
IN AN INFANT.—Dr. A. JACOBI presented a case, occurring in
the practice of Dr. H. Moeller, of remarkable arrest of devel-
opment, coupled with giant growth and the formation of mul-
tiple diffuse lipomatous neoplasms in an infant nine months
old. The child was one of two surviving out of five, and had
weighed thirteen and a half pounds at birth. Cyanosis of the
lips was noticeable; there was an extensive cutaneous telangi-
etatic formation in the right half of the thorax and abdomen;
the left foot was of gigantic size, and a curious feature of the
same was that the little toe was about six times the size of the
great toe. The right knee joint contained no patella, and volun-
tary superextension of the extremity could be carried to an
angle of 240°. The left half of the head being larger than the
right, and the left ear being situated about an inch to the rear,
gave an apparent wryness to the head. The child had a dull,
vacant expression, and had not been known to smile.

CANCER OF THE DUODENUM WITH OCCURRENCE OF THE BILARY
DUCT.—Dr. J. Adkex presented a specimen of medullary cancer
of the duodenum, with the following history: An old gentle-
man, seventy-six years of age, had for over thirty years been
the subject of an obscure affection of the stomach, of which
the most prominent symptom was a gnawing pain, which was only
relieved by the regular ingestion of food every two hours.
Until three years ago he had enjoyed robust health. A year and
a half ago he was taken seriously ill with a chill, followed by a
rise of temperature reaching 105°. The following day his tem-
perature was normal, but he had developed cholamic icterus,
which only disappeared to return with greater intensity, until
finally the patient's skin had assumed a deep-brown tinge. Both
the urine and the stools contained bilary coloring matter in
abundance. His morbid appetite had increased, with symptoms
of chronic gastritis, so that he craved food every fifteen min-
utes; still he rapidly lost ground, and finally succumbed to the
cholamic poison. The assumption of obstruction of the ductus
cholodochus by the pressure of some tumor was shown to be
correct by the results of the post-mortem examination. The
stomach showed intense catarch of its lining membrane, with
many ulcerations, which accounted for the frequency and vi-
olence of the pains experienced during life when the viscous was
empty. Relief was obtained when the ulcers were protected from the action of the gastric juice by the mass of food. The duets cholelithiasis was completely occluded by the pressure of a tumor, about the size of a walnut, which grasped the duodenum, in the shape of a horse-shoe, and which was eroded on its intestinal surface. The duets showed considerable dilatation behind the point of constriction. On microscopic examination, the tumor was found to be a medullary carcinoma. The glands were not involved.

Filariâ Sanguinis.—Dr. A. Jacobi showed a sample of chylous urine obtained from a patient twenty-seven years of age, a native of St. Thomas, W. I., who was the subject of filaria sanguinis. At irregular intervals dysuria would occur, followed by the passage of hard, nodular bodies, and subsequently of milky urine. The trouble had disappeared entirely for a considerable period after an attack of scariatrins. The administration of turpentine had caused temporary improvement. On several occasions copious haemorrhage had been observed upon the urinary passages; the specimen under consideration likewise contained blood. His sleep was disturbed; he was in good general condition. The presence of the parasite had been demonstrated and photograpbic reproductions secured, which, however, seemed to differ somewhat from those represented in the Transactions of the Society for Internal Medicine, of Berlin.

Recurrent Tubercular Disease of the Wrist: Amputation. Operation for Periopleuritic Abscess.—Dr. A. G. Geister presented a hand, the seat of fungous degeneration of the wrist joint and accessory structures, removed from a tuberculous boy seventeen years of age, who had also bad cold abscesses of the sternal region from costal caries.

Dr. J. A. Wyeth had performed resection of the carpal joints by Lister’s method of lateral incisions, and had removed the heads of two of the metacarpal bones and all the bones forming the wrist joint, with the exception of the trapezium and os pisiforme. A plaster cast of the extremity had been taken prior to operation, and, when Dr. Gerster took charge of the case, the hand still presented precisely the same conformity as that shown by the model. The whole cavity remaining after the operation had gradually become filled up with fluffy granulation tissue, showing here and there points of cheesy degeneration. The sheaths of the flexor tendons being evidently involved, and the boy’s general condition admitting of no delay, the useless member was amputated. On the same occasion the carious rib was resected, disclosing an extensive periopleuritic abscess, which had dissected up the thickened pleura from the chest wall. The lungs and pleural cavity were intact. The patient was now rapidly recovering.

Exsection of the Wrist Joint.—Dr. Geister also reported the result of a recent resection of the wrist joint for extensive phlegmonous suppuration of the parts. A laborer, thirty-four years of age, had a deep phlegmonous abscess of the hand, which had been punctured in the customary manner until sinuses had formed which led down, at various points, to the disintegratéd and suppurring joint cavities. Langenbeck’s method of longitudinal dorsal incision was selected, and the heads of the three middle metacarpal bones, as well as the lower ends of the ephiphyses of the bones of the forearm, to the extent of 2-1 cm., and all the bones of the wrist joint, excepting the trapezium and the pisiform, had been removed. Lister dressings were applied, and the extremity was suspended in one of Esnarel’s interrupted resection splints. Primary union of the rather extensive wound was secured, excepting at the points of drainage, and by the twelfth day its condition was such as to admit of passive motion. In spite of considerable shortening, the functional result was excellent. The favorable result was due, in a great measure, to the satisfactory general condition of the patient, who, he regretted to say, had failed to put in an appearance that evening.

Dr. Oberndorfer made a supplementary report of his case of specific primary lesion on the eyelid as presented at a previous meeting, to the effect that up to date no general constitutional manifestations had been observed—a circumstance he attributed to early mercury treatment.

Diphtheretic Infection through an Ear-Ring.—Dr. A. Jacobi related the history of a case illustrating the conveyance of contagium of diphtheria by means of an ear-ring. The patient, a little girl, seven years of age, had been removed from home during the course of her sister’s fatal illness, and had returned on the day of the funeral. The ear-rings which the deceased child had worn had been superficially cleansed, and given to the sister to wear two days later. Shortly after, one of the ear-ring holes became inflamed, and the next day the lobe of the ear was covered with a white deposit; soon after, a previously existing blistered surface behind the other ear had a diphtheritic membrane formed on it, and a day later diphtheria of the pharynx was developed.

Dr. Adler recalled a similar case observed by him at Dr. Jacobi’s clinic. A child had a navas which had been destroyed by the actual cautery. She had remained in good health, although in contact with other members of the household who at the time had diphtheria, until the eschar separated, when the fresh surface of the wound thus exposed at once assumed a diphtheritic character; the disease became general, and rapidly ended fatally.

Quinine as a Preventive of Typhoid Fever.—Dr. A. Mayer asked whether quinine was considered to possess prophylactic virtues against the contagium of typhoid fever. In a case in point, an epidemic of typhoid which had broken out in a country hotel, six relatives who had remained in attendance on the patient had taken six to eight grains of quinine daily, and had not been affected, whereas one who had neglected to do so had contracted the disease.

Dr. Scharlay expressed serious doubts as to the possession of any such properties by quinine, since he had observed cases of typhoid in patients who had previously habitually taken large doses of the drug for malaria.

Dr. Jacobi did not attach any value to inferences deduced from so small a number of observations. The quinine might have had some indirectly beneficial effect as far as its tonic properties were concerned, but, to obtain any disinfecting action upon the blood, the introduction into the system of several draçums daily would be requisite.

A. G. Geister, M. D.,
Secretary.

Letters to the Editor.

THE ETHICS OF SENTIMENT AND THE ETHICS OF PRACTICE.

Elberon, N. J., July 19, 1883.

To the Editor of the New York Medical Journal:

Sir: As illustrating the practical value of the American medical code, let me give a bit of personal experience. I have a faculty living at a considerable distance from me, in the city, who frequently require attendance in the night, or at times when it is inconvenient for me to respond. Finding that a practitioner (a good many years my junior), in whose professional ability I had confidence, had opened an office in the vicinity, I requested them to send for him for any emergency. I also called on the doctor and explained to him the special case for
which his services were most likely to be required, and the treatment I was in the habit of employing for immediate relief.

Soon after this I noticed that I was no longer called to the family, and, meeting one of them casually, I learned that my friend had been sent for as I requested, and was carrying out a continuous plan of treatment based upon examinations of urine, etc., and that he was promising radical cure where I had obtained only temporary relief, the trouble returning whenever the patient departed from the rules which I had laid down. I have now in my possession a lengthy schedule of diet and medicines which he had drawn up for the guidance of my patient.

A few days later I had the pleasure of reading in one of the journals a vigorous article from the pen of this same doctor in defense of the Code of Ethics of the American Medical Association, in which he expatiates at considerable length upon the lowering of professional tone which would follow its abandonment. Very truly yours,

A. H. SMITH.

THE FUMES OF SULPHUR IN THE TREATMENT OF CATARRH.

NEW YORK, July 16, 1883.

To the Editor of the New York Medical Journal:

Six: So much has been said regarding the inhalation of the fumes of burning sulphur as a cure for catarrh, I take the liberty of inquiring through the columns of the journal as to a method of using the same.

Will you please give space to this, with any suggestions which you may think applicable, or permit others so to do?

Yours respectfully,

R.

Miscellany.

The St. Louis Medical Society.—We have been asked to publish the following:

On June 23, 1883, Dr. Atwood introduced the following, which was adopted by the St. Louis Medical Society, after some considerable discussion:

Whereas, At the recent session of the American Medical Association, a preamble and resolution were offered for the consideration of said association, purporting to represent the sense of the St. Louis Medical Society upon the propriety of preparing a new code of ethics, or altering and changing the existing code in accordance with the present relations of the profession; and

Whereas, In said preamble the assertion is made that "the code has accomplished all it was designed it should, but at present many of its features are obsolete and not adapted to our wants. The necessity of an early revision is very apparent, is loudly called for in all parts of our land, and can not be refrained much longer. . . . The time has come when the loud and very soon universal call will have to be heeded"; and

Whereas, The St. Louis Medical Society did not instruct "That the committee be authorized to prepare a code of ethics which in their view will meet the wishes of the profession, and submit the same to the meeting of 1884"; therefore,

Resolved, That the St. Louis Medical Society distinctly repudiates the statements contained in said preamble, and again expresses its fidelity to the existing code of ethics as a time-honored and most suitable fundamental law of the profession, and specially deprecates any action calculated to reflect upon its loyalty to those principles which have heretofore secured immunity from the machinations of schismatics within or enemies without.

A. H. OHMANN-DICHIENZI, M. D., Recording Secretary.

A Renal Form of Typhoid Fever.—Dr. Dillion has chosen this subject for an inaugural dissertation, and comes to the following conclusions: Typhoid fever produces a renal congestion, which plays an important part in the course of the disease. Albuminuria is almost constant, but generally slight and temporary; when abundant, it is a sign of true nephritis. The renal inflammation is both parenchymatous and interstitial, and produces certain characteristic symptoms, such as asthenia, stupor, dryness of tongue, edema of the face and legs, lumbar pains, cutaneous eruptions (pemphigus, erythema, boils), and an alteration in the color of the urine, which has a reddish color and the odor of boiled bread; in the deposit, red and white corpuscles are found, as well as casts; the urine contains a large quantity of albumin. The diagnosis can easily be arrived at by the above-mentioned symptoms. The termination is often fatal, either from asthenia or uraemia. As to the treatment, Bouchard recommends carbolic acid and the salicylates, Polli the sulphates, Klebs the benzoate of potash. Lecchee, mustard poultices, and cupping in the lumbar region are useful; but blisters, with the addition of caustics, must be avoided. In certain cases, the disappearance of the symptoms is accompanied by abundant diuresis, which ought, therefore, to be favored if possible; but all diuretics are not equally good: those which possess irritating properties must be avoided. The best in these cases is milk, pure, or mixed with water. Whatever may be the way in which it acts on the kidneys, it is always well borne, and its action is double: it increases the secretion of urine, and hastens the elimination of toxic principles, without producing any irritation, even in the most acutely inflamed kidney. Subcutaneous injection of pilocarpine might perhaps be useful; in one case, when the skin was dry and burning hot, Dr. Dillion injected twice daily six or a grain of a grain of pilocarpine, and under its influence the skin became moist, and abundant sweat was produced; the tongue also was less dry than before; the temperature fell in two days from 105° to 96° F.; but three days later the patient died, after the temperature had once again reached 104° F. New investigations are necessary before we can arrive at definite conclusions. As for the cold bath, Gubler thinks that they are contraindicated in case of nephritis, but Liebermann considers their use as surely beneficial in spite of it. Several patients who had been subjected to that treatment did complain of any inconvenience, and cold lotions rapidly applied to the trunk and limbs with a sponge seem to relieve the patient, lower the temperature, and re-establish the functions of the skin. All these advantages must be weighed against the danger of a renal congestion; but further experience alone can show which treatment is most advantageous.—British Medical Journal.

Army Intelligence.—Official List of Changes of Officers of the Medical Department, United States Army, from July 14, 1883, to July 21, 1883.—Magruder, D. L., Lieutenant-Colonel and Surgeon, Medical Director headquarters, Department of the Missouri. Granted leave of absence for one month, with permission to apply for an extension of one month. S. 0. 145, Department of the Missouri, July 12, 1883.——Elkrey, Frederick W., Captain and Assistant Surgeon. The leave of absence granted on surgeon's certificate of disability by S. 0. 26, A. G. O., January 31, 1888, further extended six months on surgeon's certificate of disability. S. 0. 162, A. G. O., July 16, 1888.——Powell, Jenius L., Captain and Assistant Surgeon. Assigned to duty at Fort Columbus, N. Y. H. S. 0. 130, Department of the East, July 18, 1883.——Richards, Charles, First Lieutenant and Assistant Surgeon. Assigned to duty at Fort Adams, Newport, R. I. S. 0. 130, Department of the East, July 18, 1883.

Naval Intelligence.—Official List of Changes of Officers of the Corps of the Navy for the week ending July 21, 1883.—Dr. Horace Brown Scott, appointed an Assistant Surgeon. Reported by Assistant Surgeons Charles W. Brant, Dr. Oliver Diehl, J. H. Bryan, and J. D. Galesword, promoted to Passed Assistant Surgeons.——Surgeon C. H. White and Passed Assistant Surgeon A. C. Heffinger, detached from the Lackawanna, the former placed on waivers orders, and the latter granted three months' leave.——Surgeon T. Woolerton, detached from the Naval Hospital, Philadelphia, on the 31st of July, and granted leave of absence for one year, with permission to leave the United States.

Society Meetings for the Coming Week.—Thursday, August 29: Society of Physicians of the Village of Canandaigua, N. Y.; Medical Society of the County of Cayuga, N. J. (Tom's River).

Corrigenda.—The following corrections should be made in our issue of July 14th: In Dr. Skene's lecture, p. 33, first column, sixth line from the bottom, for "womb," read "wound"; in Dr. Blodgett's article, p. 36, second column, twentieth and nineteenth lines from the bottom, for "costal cartilages," read "costal dislocations."
Lectures and Addresses.

CLINICAL LECTURES ON DISEASES OF THE SKIN.
DELIVERED AT THE NEW YORK HOSPITAL,
By L. Duncan Bulkley, M. D.,
Physician to the Out-patient Department—Class of Venereal and Skin Diseases.

Lecture I.
Psoriasis Treated with Chrysophanic Acid.—Eczema Rubrum.
—Eczema Rubrum with Varicose Veins.—Recurrent Eczema.
—General Diffuse Poplar Syphilitic.

Gentlemen: At the beginning of each lecture we will show the patients, and, if time allows, I wish at the close to spend twenty minutes or half an hour in didactic review of what we have seen. Our clinic depends upon the material sent to us and upon our out-door service here, so that I can not always command the cases in the order in which I wish to present the subject. I shall therefore have to take the cases in a desultory manner, and afterward group them together. I will first show you some simple cases before we commence the study of the more obscure ones.

Case I. Psoriasis Treated with Chrysophanic Acid.
—This case is very interesting, from the fact that, without our intending it, we have had quite a remarkable improvement in the eruption from a treatment which has been advised, but which has not been frequently employed—namely, the internal use of copaiba. The patient came here first on account of a gonorrhoea, and not for his psoriasis, which he had had for twelve years, and was put on the treatment for gonorrhoea—on what is known as the Lafayette mixture—a mixture containing an alkali and a little spirits of nitre. When he first came, on April 12th, the psoriasis was in full bloom, very much more marked than now. He was given the mixture of copaiba, but with no local treatment, and as his gonorrhoea diminished his psoriasis greatly improved, so that now his eruption is not of half or quarter its former extent. He says there are no new spots, and, as you see, the eruption is fading. His name is J. B., aged twenty-four. He has had psoriasis for twelve years, with occasional improvement, followed by relapses or increase of the eruption from time to time, it having never entirely left him since its first appearance. What I show you now is not the eruption of psoriasis as you are apt to see it; it has decidedly faded, some of the spots have disappeared, and many are much broken into. On the elbow you will still find the white, slightly adherent, imbricated scales, which very readily come off with light scraping; they are seated on a red base, which, as always, is perfectly distinct and sharply defined, and not with the indefinite outline commonly seen in eczematous patches. On scraping off the scales lightly we soon come to a membranous pellicle, which is adherent, and, if the scraping is carried still further, this comes off and is followed by the appearance of a drop of blood. The eruption, as you see, consists of dusky-red spots, of a size varying from that of a minute pin-head to almost any size, always sharply defined, tending to cover themselves with a white scale, which, on being scraped off, leaves a red base, which bleeds very readily. Remember that the separate spots of psoriasis always appear first as small points, gradually enlarging, and that even when seen as patches of large diameter they have always thus begun; in some localities you may observe the mode of disappearance of the eruption, it gradually fading out, the scales ceasing to form, and finally the redness itself vanishing. We see on the legs very much less eruption than is usually seen on these parts; as a rule, in psoriasis, the legs have more of the eruption proportionately than the body; almost always the patches are larger on the lower extremity, more scaly, and of a darker hue.

Differential Diagnosis.—Why do we speak so confidently of its being psoriasis, and state that it is absolutely impossible that it could be anything else? The reasons are found in the character of the lesions, taken in conjunction with the history of the duration of the eruption. There are only four eruptions which could with the slightest reason be supposed to be the one before us; these are: a squamous syphilitic eruption, an eczema, a ringworm, and psoriasis. First, of syphilis: this man has had the eruption for twelve years, with varying severity, and this eliminates syphilis absolutely, as such a general syphilitic eruption never continues that number of years. You may have an ulcerative syphilide for five or more years, but never an acute, distinct form of this kind. In the next place, the syphilide would be on the flexor and extensor aspects alike, while in psoriasis the extensor surfaces are always the seat of preference. In the general large popular syphilitic eruption you could never have any such extensive patches of disease as are seen on this man's legs.

Second, in regard to any possible form of eczema which might be mistaken for the present eruption. Eczema seldom, if ever, presents so many separate points of eruption as are seen here; and it may be said that it never exhibits so many of such small size and so sharply defined. Upon some portions of the body psoriasis may resemble eczema, and you see the characteristics it very commonly may take on of the lower extremities—namely, the patches are larger, more dusky-red, and of more undefined outline, often more resembling an eczema of the lower extremity. It would be difficult, but not impossible, to make the diagnosis from the eruption on the lips alone.

In certain points this eruption might be thought to resemble ringworm, but yet you would certainly not have such a vast expanse affected with the parasitic disease, and an examination of the scales by the microscope would show the parasite in the latter. The individual spots present differences from those of body ringworm in the pearly character of their scales, the absence of a clearing in the center, and the rather livid redness of the base of the psoriatic spots. We then make the differential diagnosis from syphilis, eczema, psoriasis, and ringworm; and, recognizing the lesions of psoriasis, we conclude with certainty as to its nature.

This patient continued the use of the balsam of copaiba.
until the eruption was a good deal faded and broken up,
and some weeks ago he was put upon another treatment
which has recently been advocated. He has been under
the internal use of chrysocephalic acid, which has been re-
ported on favorably by several observers, some claiming
brilliant results from it. I have several patients under this
treatment, but am not ready yet to speak definitely concern-
ing it. He began with a quarter of a grain, in a powder
with sugar of milk, taken three times a day directly after
eating; and a week ago I doubled the doses. It is best
always to begin with a quarter of a grain, and after a few
days give half a grain, and then a grain, until some effect
is produced on the stomach or bowels. Some patients are
said to have taken up to four or five grains several times
daily. When you get to five grains there is sure to be
purging and vomiting. He is under this treatment, and has
not had any effect from it as yet; but we shall continue it
for some time to come, and I propose to push this treat-
ment in as large a number of cases as possible. I wish to
give you at the present time the diagnosis and treatment in
these cases as we see them, and the theory of treatment I
will give you later in the course.

CASE II. ECZEMA RUBRUM.—I bring you this woman
to show you a leg which is scaly. It is a case of eczema
rubrum of the left leg. She is forty-three years of age,
attends to her own household work, being therefore more
or less constantly on her feet, and has had an eruption only
on this leg. I merely want to show you that, although an
eruption is scaly, although it is red, it may not be psoriasis.
No case of eczema ever becomes psoriasis. The patient
states that she had erysipelas eleven years ago, and that it
broke out again two years ago and settled in her back. You
will see a great many cases which are called erysipelas, and
chronic erysipelas, of the face, etc. We all know there is
no chronic erysipelas. It may be chronic by recurrence,
but not such an affair as this. This is chronic eczema,
which never presents numerous well-defined, sharp patches.
See how uneven the edge is, and how it shades off into un-
healthy skin; you get a certain amount of erythematous
skin, you get it on half of the body, or, if on the whole
body, in continuous patches. This is erythema rubrum,
and is one of the cases which, of all others, are per-
fected treated with the rubber bandage. I am sorry I can
not put it on to-day, to let you see how to do it. I am
afraid this patient does not put it on tight enough. If this
leg were exposed to the open air it would crust over, and if
closed up at night there would be a surface that would ex-
cude moisture. Leave it alone and exposed to the air and
that moisture tends to dry. If she had left it alone, un-
treated, and had scratched it, it would have a large crust;
if treated with the rubber bandage there would be no crust
upon it, but the scales would come off on removal of the
bandage. She states that she left off the bandage for over
a year, and that the leg was in as good condition as this
until August; but in August, from over-fatigue, she had
the eruption develop in spite of the bandage. The tongue
is quite indented, and considerably cut; her bowels act
every day; her water is very much colored, and stains the
vessel considerably. She is taking some medicine, but I do
not know what it is. We expected her to say the water
was stained. Most of the cases of eczema of the leg are
connected with highly colored urine, with a heavy sediment
of lime, or some other deposit, from imperfect elimination
by the kidneys. It always recurs from over-fatigue or over-
exertion.

Differential Diagnosis.—There is nothing like this dis-
 ease at all, except psoriasis, and that does not come in such
a profuse form.

With regard to local treatment, the bandage is the great
thing; it is an invaluable addition, and she would hardly
know what to do without it. We shall later on have an
opportunity to see it put on, and then I will speak of the
mode of treatment. For internal treatment you generally
give diuretics, a cathartic, and usually some tonic with all.

I pass to you some plates of eczema, and one of these
is a plate of Dr. Fox's, of eczema of one leg, the other leg
having a tubing on it. I do not think that is employed
now, but that Dr. Fox has himself discarded it. This form
of eczema is usually attended with varicose veins, but in
this case I find none.

CASE III. ECZEMA RUBRUM, WITH VARICOSE VEINS.—
Mrs. Deon, aged fifty-two. She has had a milk-leg—that
is, the left leg was affected twenty-two years ago, and again
nine years ago. About December 1, 1880, an ulcer made
its appearance on the left leg from which there are large
sacs, and an eruption shortly appeared after it, and gradu-
ally extended up the leg, involving the greater part of the
leg when first seen, January 1, 1881. I show you these
patients that come back to us, as they are instructive. We
get them well to a certain extent; they leave, and there is
a relapse. Many of the eruptions have a predisposition to
return. She first came to see us January 26, 1881, and was
here under treatment for two or three months. She got
well under the rubber bandage, then she disappeared, and
we did not see her again until September, 1882—a year and
a half, which is, of course, a good immunity for a person
who is on her feet all the time. The trouble came back in
September, and it began on the 22d, four days before she
was seen. Here we have the same lesion as in the former
case, accompanied with varicose veins, with very considera-
ble varicosities of the feet. We note here an erythematous
condition, which disappears entirely on pressure and readi-
ly returns on taking away my hand. You notice the edema
of all the parts. Most cases of eczema of the leg are asso-
ciated with edema, which is not necessarily owing to kid-
ey causes. In this instance it is secondary to the milk
leg, or phleagmasia, she had first twelve years ago, and again
nine years afterward.

I think, if we want to have our patients remain cured,
we must require them to wear the bandage continually, just
as persons with certain deformities of the body require the
continual use of a bandage or truss; for, as a consequence
of leaving off the bandage, we get an affair which seems
like a purely local disease, but, in my judgment, is not a
local disease. You see some persons with varicose veins
who do not have the eruption at all, while others, without
having varicose veins, have the eruption. This is, I believe,
wholly constitutional. We put her upon the treatment
which is commonly prescribed here, and you will hear frequently of it; but I hope you will not consider it routine practice—that is, the diuretic treatment. She is taking the acetate of potassium; it relieves the congestion of the skin, and certainly removes the disease. She is now taking thirty grains three times a day, in a little rhubarb-and-soda mixture, which is mainly used. Locally she has applied an ointment of salicylic acid and balsam of Peru. I merely mention that ointment, but can not speak further about it now; it is composed of about half a drachm of salicylic acid and a drachm of balsam of Peru to the ounce.

Case IV. Recurrent Eczema.—I now show you a case of recurring eczema in a child whom I showed you last year—a child who, when you saw her then, had an eczema all over the neck. She remained entirely well until this fall. We saw her here last March, with a history that when six months old she had an eruption lasting until eighteen months ago—I am reading the first record of March, 1881—and this eruption had been on the head for twelve months when we saw her. The head was the seat of a squamous eruption, and all the upper part of the neck, back, and chest was likewise affected with eczema rubrum. There is some moisture there now. She is over four years old, and, you see, is an exceedingly small child for her age. When you saw her last year the entire neck was the seat of a moist, exuding eruption. The head was entirely crusted over, and the child was suffering very considerably. There were enlarged glands in the neck, indicating a low vitality and a serofulous condition. What she shows to-day is a small amount of scaling, which I wish you to look at closely. I want you also to see this eczema of the eyelids in a child, because such patients are taken to oculists and treated with blue-stone for years, while, if treated as eczema, they would get perfectly well. You see here a swelling of the lids which would not be here if it were not for this eczematous spot, and you find the remains of eczema on the lips. That, of course, may vary to any extent; there may be a thickened eyelid, and when you find it in eczematous subjects you can be pretty sure it can not be cured without proper constitutional treatment. There is a slightly reddened condition of the eyelids—a puffiness of the whole region of the Meibomian glands. Now, here we still see a certain amount of redness, and a certain amount of erythematous thickening, as the remains of the eczema. I have not seen her for a long time.

Eczema of the eyelids is treated frequently with stimulating solutions—with nitrate of silver, blue-stone, etc., without effect, until the proper treatment for eczema is used. The erythematous condition of the neck is hardly worth seeing. She is better than she was a year or so ago. It is a little over a year since the child had any treatment at all. The scalp was crusted over and the hair matted down, and there was some eruption on the upper lip and on the arms when she came here, September 20th. She was given the syrup of the iodide of iron, a teaspoonful three times a day, and locally she was to use the ointment which you will see continually used, namely, the tar-and-zinc ointment. It is composed of half a drachm of oxide of zinc, two drachms of tar, and six drachms of simple ointment, or rose ointment. That treatment has been continued from the first; she has had nothing but the iodide of iron and the tar-and-zinc ointment. I do not generally use the treatment with the iodide of iron in eczema; that was given in my absence. Although I do not wish to reflect any discredit upon this treatment, yet I do not use it; I do not know why, but I have not been as well satisfied with it as with other treatment. I shall put the child on a little arsenic and ammonia, or the citrate of iron, or the citrate of potassium and sweet wine of iron, made with Malaga wine, under which, I think, such patients improve faster than under the iodides.

Case V. General Diffuse Papular Syphilide.—I show you quite a different eruption now, gentlemen, in a case of specific disease. I will say, once for all, that I consider it a good deal better to use the term specific disease, and I only use it for one disease—syphilis. Whenever I use the word specific it refers to that, and that alone; it saves me explanation and uncertainty. It is a case of early general diffuse, or general scattered, papular eruption from syphilis. The patient is a widow. She had one child, who died soon after birth. She has had the present eruption for the past three months. When seen a week ago, all the body, face, hands, neck, arms, and legs were covered with the grouped papular syphilide, and she has mucous patches in the mouth.

I show you the case, gentlemen, for you to compare with the first case I showed you, the case of psoriasis, which in appearance this resembles to a slight degree. Here is a moist eruption which somewhat resembles psoriasis, but the scales of specific disease are always slight as compared with psoriasis. Specific disease does not tend to cover itself with scales, except in the tuberiform form. This is a little dark, a little large, and a little too prominent to be confused with psoriasis. Here is a very interesting point: you find here what is termed psoriasis of the hand, or what is sometimes called psoriasis palmaris syphilitica. Now, in any case of psoriasis you will not find spots like that developed in the palms of the hand. If there is doubt in your mind, there is a point which would argue nine out of ten times in favor of its being specific disease. This is a general, large, specific papulide. This woman's primary lesion must have attacked her within six months. There is no eruption on the soles of the feet. There is sometimes seen a little circular grouping of the lesions, but it does not happen to occur in this case; when it does occur it is perfectly pathognomonic. Here is the general large papular syphilide that might have been covered with more scales, and might in certain other cases represent psoriasis. Here is a wax model of the lesion; they call it syphilide palmaire, but there is no propriety in calling it that. Now, you notice I have made this diagnosis without a word from her. I do not care whether she had the primary lesion or not; there are characteristics which are absolutely positive. You will see the spots are solid, and are erythematous, and disappear on pressure; they are not stains; they may be acute and new, and there are also some stains left from the former lesion. There is some little analgesia, or loss of sensitiveness to pain, during the early acutely developed phases of
syphilis. It is more common in women than in men. I have patients on this platform into whom I could stick a pin without their knowing it. There is entire loss of sensitiveness. We have here a general diffuse papular syphilitic on the face, as well as on the body, and I should suspect the face if there were none on the hands. There are features here which might be mistaken for those of acne, and might be something else; but one point would lead us to diagnosticate syphilis, and that is the scattered appearance which the lesions present—I mean covering the whole face. You see an acne group, but never see an acne on the lip in that way.

She is under the "mixed treatment." I believe in giving her a slight amount of hydrargyrum early in the disease, and I believe occasionally a little iodide added to it will help the disappearance of the eruption. She is taking a mixture with a little iodide in it, because it does hasten it, in my judgment. She has been under the treatment only a week or ten days, and the eruption is getting somewhat less than it was.

TRICHINIASIS
IN ITS RELATION TO
PUBLIC HEALTH AND NATIONAL ECONOMY,
BY FRANK S. BILLINGS, VET. SURG.,
BOSTON.

Third Article.

AMERICAN HOGS MORE INFECTED WITH TRICHINE THAN EUROPEAN.

Comparison of the statistics here given demonstrates, beyond all question, that American hogs are more liable to trichinosis than those of Germany.

The hogs which have been examined here have all been Western (except those examined at New Orleans, which are reported to be somewhat Southern [1]), yet no one well acquainted with the circumstances would assert that the hygienic conditions under which our Western hogs are raised are not superior to those of the famed "home-fed porkers" of the small New England farmer—raised, as they almost always are, in dark, loathsome, poorly ventilated pens; only too frequently under stables, with the house-vaults and sink-drains emptying into them.

I should mention that it has been, thus far, impossible for me to make any valuable examination of Massachusetts hogs, there being no disposition upon the part of State or local authorities to aid in such a matter, and, consequently, no material could be obtained.

As to German hogs, whoever has been upon a tour of observation through the agricultural districts of that country must have been struck most forcibly with the absurd non-hygienic conditions under which, not only hogs, but all domestic animals are, in general, raised, in comparison with those of our own country, especially of the West.

In making examinations of hogs with reference to trac-
According to the best German authorities, it requires from five to seven days for newly introduced trichinae to produce symptoms.

No "large American packing-house" keeps a lot of swine on hand for from five to seven days, for they kill them as soon after arrival as possible. They could not make money, or handle the numbers they do, did they do otherwise. It would be absolutely impossible to kill from 1,000 to 3,000 swine a day were they to keep them on hand; no packing-house has pen-room enough to keep them.

While the remarks of Bollinger are so erroneous with reference to the system of procedure at our packing-houses, they are absolutely true, not only of many small slaughter-houses, but still more of home-killed hogs, among our farmers. These hogs, however, find ready consumption here, few, if any, being sent to Europe, some being sold in our markets as "home-fed pork" by persons who "know all about the man who raised them."

Here let me say there is a prejudice, at least here in Boston, in favor of this "home-fed pork" against Western; my opinion is, that, so far as cleanliness of feeding goes, the balance is strongly in favor of the Western hog, trichinous or not, as compared with that of New England.

Bollinger says further: "The refusal from slaughtered swine at such large establishments is sold to the neighboring farmers as food to fatten their swine upon, and thus helps to swell the percentage of trichinosis in American pork."

Unconditionally false!

His report ends thus: "It is therefore right to warn the people against the consumption of American pork," unless it has been submitted to the most stringent microscopic examination.

We would say this measure is equally applicable to all pork, European or American.

THE DISEASE IN SWINE.

Numerous feeding experiments with trichinous meat were made at the Berlin school (the results being given in an able paper by Professor Mueller).

It has been proved that the consumption of such meat by swine with the sequential development of embryos in their intestines, and their migration and lodgement in the muscles, may, indeed, cause disease, but that the phenomena of the same prove neither that constancy nor distinctness of character which will admit of diagnosis of the disease during life.

All the swine thus fed became ill within a few days after consuming the meat. The following were the most constant phenomena presented to observation: Diarrhea, but not constant, being frequently interrupted by the passage of solid feces. Sometimes it failed altogether. Phenomena indicating abdominal pains were frequently observed, such as uneasiness, burying themselves in straw, etc.

These phenomena, either singly or collectively, may be observed in swine, entirely aside from any anticipatory trichina infection. They simply indicate the action of some irritant within the intestinal canal, and in this case (where the trichinae had been fed), if swine die or are killed, we should find the same pathological phenomena as in an intestinal catarrh of similar degree of intensity, plus trichina, which could only be discovered by the microscope.

"With the gradual cessation of the migration by the parasites, the abdominal symptoms become less marked, and finally disappear, to be followed by those indicating some disturbance of the motor functions. If the latter do not lead to death, they, in their turn, gradually cease with the encapsulation of the parasites."

Although the presence of trichina within the intestines causes diarrhea, yet, in these animals, it was impossible to find any embryos in their feces.

This by no means excludes the possibility of finding them in other cases; their passage away with the feces must be, in a measure, retarded by their being buried in the profuse layer of mucus which is the product of the irritation caused by them. In none of these swine was it possible to discover anything resembling the oedema which is observed in man under the same circumstances, and which serves essentially to strengthen the diagnosis of the disease.

Leisering,* of Dresden, has also made numerous experiments upon swine with trichinae. He says: "One can not speak of a 'trichina disease' among swine which is characterized by any distinct and pathognomonic phenomena. In this regard, trichinae deport themselves similarly to the cysticerus—measles."

Gerlach † says: "About two fifths of the hogs fed with infected meat were either not affected thereby, or but very slightly; the remaining three fifths were manifestly sick."

"The slight cases presented nothing of diagnostic value, while in the severe ones the symptoms were not of such a character as to indicate the true nature of the disease."

"After an attack of trichiniasis, the hog becomes again as well as ever, and can be fattened as well as one that has not been infected."

"In cases which apparently pass over symptomless, or when the infected animal betrays but slight constitutional disturbances, the infection is still of sufficient degree to make the flesh a dangerous article of food."

"Hogs are more susceptible to trichina invasion at an early age, old ones being more difficult to infect."

"Death results in over one half of the extremely severe cases."

Trichinae can only gain admittance to an organism and cause infection by means of the mouth and digestive canal. Notwithstanding the apparent negation of the Berlin observations, we have the very best authority for affirming that intestinal and embryo trichinae leave the autotoxic organism with the feces.

Leuckart says: "As the sexually matured trichinae accumulate in great numbers in the intestines of an autosite, and as the irritation caused by them leads to the development of a more or less severe diarrhea, it is evident that the young must be taken up and pass off with the feces, and not only free embryos, but also pregnant females, are subject to this removal, which has been sufficiently attested.

† Die Trichinae.
by my own observations and those of Vogel, Kuhn, Gerlach, and others. This form of migration, under favorable circumstances, also contributes to the further distribution of trichina. Heubner and Gerlach quote cases where they intentionally caused trichinosis among young swine (the non-trichinous condition of which they at first assured themselves of) by causing them to live in the same pens with such as were known to be infected. Such embryos and pregnant females become mixed with the manure and bedding of the hog-pens, or pollute the grass and ground, and may be taken up by other swine, or even by the original autotises, as they root over such material, and consume whatever they may find to their liking.

In the foregoing we have a course of invasion in which swine are the only factors. Is there no other factor or factors playing an active part in trichina invasion? It has been previously mentioned that wild swine have been found trichinous, also cats, dogs, foxes, and other animals; but of all autotises which lodge trichine (aside from swine and man), the rat enjoys the most sensational reputation from the entirely hypothetical etiological connection between the trichin- nasis of rats and that of swine. It is my firm conviction that, while a trichinous rat, alive or dead, may give occasional rise to the infection of one or more hogs, porcine trichinosis is due to some other, at present unknown, intermediate factor.

Leisering appears to have been the author of the rat-infection hypothesis. There is no rational reason why rats should not be trichinotic as well as swine, or even more so; they have much in common in their habits of life, and it will be found, by exact investigation, that the facts go to prove that trichinous pork (which does not exclude an outside, common source of infection) is more frequently the cause of rat trichinosis than that rats give occasion to the disease in pigs.

The following statistics of rat-infection are all I have been able to collect:

Of 704 rats from different parts of Germany, 59 were found trichinous, 8.3 per cent.; of 208 rats from German knackers, 46 trichinous, 22 per cent.; of 224 rats from German slaughter-house, 12 trichinous, 5.3 per cent.; of 372 rats from other places, 1 trichinous, 0.3 per cent.; of 326 rats from other places, 39 trichinous, 11.5 per cent.

Of fifty-one rats caught at the knacker’s establishment at Spectacle Island, Boston Harbor, thirty-nine were trichinous.

The proprietors of this place kindly gave me opportunity to examine twenty-eight hogs which had been kept and fattened at the island.

None were trichinous!

These hogs received no city swill of any kind. What flesh they received had been subjected to heat enough to extract the fats; otherwise, they were fed upon nothing but cornmeal.

Forty rats caught for me at the largest packing-house near Boston were all trichinous.

Of sixty rats caught for me at different stables in the city of Boston, where no pigs were or had been kept, but six contained trichine.

Dr. Payne examined six rats from a New Orleans slaughter-house, and found them free from trichine.

The results of the examinations of American pork, as well as rats, lead to the following conclusions:

1. Both show a higher degree of trichinosis than those of any other country from which we have any statistics.

2. The fact of the great number of trichina-infected rats, according to my idea, gives support to the greater degree of infection among our hogs.

3. I am not yet ready to accept Dr. Payne’s “trichina-free” districts; hence I see the necessity of the most thorough examination of hogs within the limits of the States or sections of the country where they are raised and fattened, not by single men, but by commissions of five, to conduct the whole, no matter what the labor or expense may be.

4. The United States Government must “face the music”; it can not sit still and quietly deny the trichinosis of our hogs. The facts are against us. Proof of an unquestionable sort is necessary.

5. If the fact becomes generally proved of a greater percentage of trichinosis here than anywhere else, we must seek the cause. The cause—the real one—one found, prevention can be made easy.

PREVENTION OF TRICHINIASIS IN SWINE.

1. State boards of health are necessary in every State.

2. Local abattoirs, where all cattle and hogs used for domestic consumption should be kept, with suitable inspection, must become the law.

3. Continued examinations of swine as well as rats in the respective States, and the prevention of all refuse from slaughtered swine ever being thrown into the pig-pen or barn-cellars.

4. All sick swine, from whatever cause, should be perceptibly isolated from healthy ones, under the supervision of a competent veterinary inspector.

5. All swine suffering from diarrhea should be isolated, and singly. The greatest care should be taken in cleansing the pens of such swine from all bedding and fecal masses.

(a) The excess from such swine should be subjected to microscopic examination.

(b) On cessation of the diarrhea, whether motor disturbances appear or not, the muscles and tongues of such swine should be “harpooned,” and the specimens thus obtained subjected to a careful microscopic examination.

6. Hogs in which trichine have been found should be branded “Trichinous”; they should be fattened singly, and should never be allowed to be sold for human consumption. Their lard could be tried out, however, to make “lard-oil.”

7. Hog-pens should have asphalt floors, and be kept scrupulously clean. The turning of compost into the hog-pens, or allowing water-closets, sink or house-drains to enter them, should be absolutely forbidden by law.

THE MICROSCOPIC EXAMINATION OF PORK.

Numerous elaborate essays have been written upon this subject, but the entire process is so easy and simple that such extended labor can well be looked upon as useless.

We have seen that natural causes offer us the point for the best and most available examination in the pillars of
the diaphragm. No trichina there, none anywhere, may be looked upon as law.

The remnants of them are always to be found, as two small stumps of muscle—flesh—immediately below the kidneys (in the dressed hog when hung up to cool out), or in front of them, when the hog is laid down.

A power of 50 to 75 diameters is sufficient for a correct examination. The necessary paraphernalia are: A few glass slides and strong covering glasses, of twice the size and thickness of those ordinarily used, a pair of curved scissors, and two teasing needles.

The modus operandi is as follows:

If at all dried, cut into the body of your specimen with the scissors, and then cut any number of small pieces, lengthwise to the course of the fibers; place them, two or three at a time, upon the object glasses, a little distance apart, then place the covering glass upon them, and gently thin them out with pressure and a slight backward and forward sliding motion of the covering glass.

In the face of all contrary assertions, this will give a better chance of discovering the trichina in fresh meat than by teasing out, or other method.

It is not necessary to cleanse the glasses for each specimen to be examined.

To determine if the parasites still live, place the object glass over heat for a second or so, and then place it under the microscope, and they will be seen to move in their capsules.

Salted pork is best examined by cutting it into suitably thin pieces and placing them in warm water for a few moments.

Doubtful objects which may be seen in the examination for trichina.

It not unfrequently happens that the capsules become abnormally thickened and the parasites dead within them.

In other cases calcification takes place to such a degree as to entirely change the appearance of both capsule and contents. Treatment of such capsules with hydrochloric acid will render the diagnosis easier.
Again, cysticerci—measles—perish and become calcified; these objects are larger than trichina capsules, and are often filled with a caseous mass.

The sacs of Rainey, or, as they are also termed, "psorospermia," are elongated, granulous bodies, like trichinae, intra-sarcolemmatous. The true nature of these bodies is still an open question, as well as their pathological importance. By trichinae, the striation of the fiber is entirely destroyed within the capsule—that is, it is not to be seen alongside of the parasite, while in cases of psorospermia it is retained and to be seen at the side of the object, and continuing directly from its extremities.

Bruch, Virchow, and Leuckart have described peculiar roundish or oval objects of a whitish color and variable dimensions, which are sometimes to be seen in the flesh of hams, and which have been found to be made up of needle-like crystals. They fill the fiber to a varying degree without otherwise disturbing its contents, and disappear upon treatment with hydrochloric acid, the striation of the cell again coming to view.

PROF. ERCOLANI'S RECENT INVESTIGATIONS OF THE ANATOMY OF THE PLACENTA.

BEING A REVIEW OF THREE LETTERS ADDRESSED BY HIM TO PROFESSOR ALBERT KÖLLIKER.

BY HENRY O. MARCY, M.D.

BOSTON.

(Concluded from page 21.)

In the second letter the causes are examined by which the anatomical school of Kölliker was led astray in its decisions concerning the intimate structure of the placenta in woman, which, as has been said, is identical with that of the superior simia. The origin of the mistakes with regard to woman is twofold. Some of them spring from the same idea that hindered a knowledge of the structure of the placenta in the mammifera—namely, that the decidua and the placenta are the product of a transformation of the whole uterine mucous membrane. Others have arisen from the fact that in studying the intimate structure of the organ the opinion has been derived from its examination when completely developed, without taking into account the changes that must of necessity take place in its interior from the first period of development, in which the two parts, maternal and fetal, which compose it, can easily be separated (as in the non-deciduates and in some deciduates), till the organ progresses and arrives at the second period or at complete development, in which the two component parts are so intimately united as in nowise to admit of separation. The observations made on the formative process of the decidua and the placenta in the vertebrate mammifera warrant the assertion that if the decidua in woman was really derived from a transformation of the pre-existing uterine mucous membrane, it would be a fact quite exceptional for the human species, or, rather, which the human species would have in common with only the higher simia.

Before undertaking to show the uncertainties and contradictions which one is compelled to accept as truths—in entertaining the opinion that the decidua in woman is derived from a transformation of the uterine mucous membrane, and not from a neo-formative process, as in all the mammifera—the author draws attention to the not recent observations of Bischoff on the peculiarities of the mucous membrane in the uterus of woman, which he has from the beginning of his labors striven to place in clearer light. And let it be observed that although Professor Kölliker, in his "Treatise on Embryology," repeatedly asserts that the decidua is developed by a transformation of the mucous membrane without a hint of the peculiarities observed in this mucous membrane, he has yet recorded and described them in his "Treatise on Histology."

But, without entering into minute particulars on this subject, which the author has treated at length in one of his preceding works,* he contents himself with noticing one fact, unanimously recognized by anatomists, viz.: that the mucous membrane in the uterus of woman does not present, and can not be detached in folds from the uterine muscular tissue beneath, as can easily be done in the ordinary mucous membranes of other organs. He observes that the reason of this fact consists in this: that the mucous membrane of the uterus in woman is not furnished with a rich stratum of submucous connective tissue, as is the case in the uterus of all the mammifera, the higher simiae excepted.

Now, this simple and general circumstance being overlooked, and the assertion made that the decidua is derived from a transformation of the mucous membrane, as if this were an ordinary mucous membrane in the strict anatomical sense of the word, occasion is given for not a few ambiguities and uncertainties. "The decidua is," according to the school of Kölliker, "nothing but the uterine mucous mem-

brane transformed, and even in the first stages of pregnancy it is exclusively formed from the hypertrophied uterine glands."

And yet everybody knows that, when the fifth month is past, the decidua is detached from the uterus, and its component elements undergo regressive phases. Is it then, perhaps, that new uterine glands begin again to form? Surely not, since Kölliker himself affirms that he has found them hypertrophied and immersed among the innermost layers of the uterus during the whole period of the pregnancy. How is it, then, that they are transformed, and that from them alone the decidua is developed, if, at the same time, they remain hypertrophied in the uterus? Is it, then, only the stratum of submucous connective tissue that is transformed? But this, as has been stated, does not exist in the uterus of woman. Perhaps the transformation is due only to the epithelial stratum of the mucous membrane. But Kölliker himself has shown that this disappears immediately after the act of conception. What part, then, is it of the uterine mucous membrane that is transformed to become decidua?

According to the author, the decidua in the uterus of woman, as in that of the mammiferan, is developed from the elements of new formation called deciduates, which derive their origin from the capillary walls of the vessels that remain uncovered by the denudation of the epithelium. Nevertheless, these cellular elements are not found opposite to the discharging apertures of the uterine glands. The hypertrophic condition of these and the fact of the hypertrophy attest their increased functional activity, and the moisture separated from them must necessarily make a passage for itself through the surrounding new-formed cellular elements. The apertures or outlets of the decidua, however, are not glands, as is believed; they are the openings that correspond to the discharging mouths of the said hypertrophied glands in the uterus. But, moreover, in that portion of the decidua against which the ovum rests, and which, therefore, will become the maternal portion of the placenta, every trace of glands is very quickly lost, as Kölliker himself asserts. The reason of this singular fact in a part which has been declared to be exclusively formed from the hypertrophied uterine glands deserves to be sought for—all the more, since in the subjacent stratum which touches the uterus evident traces of altered glands are found, even when the pregnancy has reached its term; and the reason is found in the altogether special form which vascularization assumes in the placenta of woman—a form of vascularization that completely wastes away the glands. Now, in the said part the glands have already disappeared, Kölliker tells us, before the completion of the first month; and as we know that the special form of vascularization—vascular aneurysm, that is, or lacunae—is not established until about the third month, an effect is thus ascribed to a cause which, at the very time when it was operating so energetically, did not yet exist.

From what has heretofore been said, it clearly appears that, for the author to proceed in the minute criticism of separate particular facts in order to exhibit the uncertainties and contradictions which they include, it would be necessary to quote his work in great part. It will be sufficient to mention that the examination of the well-developed uterine decidua observed in cases of extra-uterine pregnancy convincingly show that in woman, as in the deciduates and non-deciduates, the decidua is developed by means of a neo-formative process, and that the new-formed cellular elements take their origin from the walls of the capillaries.

The author follows the arrival of the ovum in the uterus up to the complete development of the placental organ in that portion of the decidua against which the ovum was arrested. He shows how those who defend the transformation of the mucous membrane are themselves forced to recognize a process of active proliferation in the decidual elements to account for the formation of the decidua reflexa. Held by this, the ovum is fixed against the new-formed decidual elements, which are vigorously proliferous, and form the obstacle which the walls of the ovum oppose to the exit of the fluid separated by the underlying utricular glands. These glands are, from the pressure exercised by the separated fluid, diluted and altered; thus take place the two strata constituting the uterine or maternal part of the placenta, the spongy stratum near the uterus, or the non-caducous portion of the placenta of Kölliker, formed from the altered utricular glands, evident traces of which may be observed even at the termination of pregnancy; and the stratum over this, developed from the new-formed decidua, or the caducous stratum of the placenta in which there never are traces of glands, because there never were any glands there. It is in this stratum that the placenta is formed; and all anatomists agree in recognizing that in the first months of pregnancy this is developed from a mass of cellular or decidual elements, traversed by a vascular network with endothelial walls only, and that among the said decidual elements the fetal villi are buried.

This is the first period of the development of the human placenta which is observed in the first three months of pregnancy; and, as long as it lasts, the fetal part can be separated without laceration of the maternal part, as happens in the mammiferan non-deciduates.

The second period of development, in which the organ is perfected and completed, and which renders it first difficult, and, later, impossible to disjoin the fetal portion from the maternal, begins, by the universal consent of anatomists, with the establishing of two facts—the rapid and exuberant proliferation of branches from the trunks of the villi, and the ecstatic process in the network of the maternal vessels. Now, these two facts occurring contemporaneously in a limited and circumscribed space, as the result of simple physical and mechanical laws, it must necessarily follow that the branches of the proliferating villi should press against the endothelial walls of the vessels, which are at the same time dilated; and the ultimate result is, that the walls of the vessels, at first simply bent in toward the internal cavity of the dilating vessel, must, as the process of aneurysm becomes more and more pronounced, completely invest the villus the more, as this fact is helped by the tension exercised upon the walls of the vessel by the proliferous branches of the villus. That this takes place has heretofore ob-
served by Weber and by Virchow, when they described in human abortions the occurrence of tufts of villi making complete hernia in a maternal vessel.

It is not possible to sum up in a few words the observations made by the author, as he follows minutely the succession of these facts in the development of the human placenta. It will suffice to say that he shows how the observations of Weber and Virchow give, in what may be styled a rudimentary form, the exact conception of the intimate structure of the completely developed human placenta, because as in this there is the appearance of the fetal villi swimming in the blood of a lacuna, it may likewise be the case in the observations cited, while in reality it is the villi that have caused hernia in the lumen of the dilated vessel, bending inward the walls at the place where they seemed to penetrate.

With these views, all the uncertainties that encumber the knowledge of the intimate structure of the placenta of woman entirely disappear, and the author shows that it is no longer necessary to suppose the penetration into the interior of the placenta of two plates—the one called by Winckler fundamental, the other of inclusion—the placental caduca and the subchorial stratum of the placenta, according to Kolliker, who does not himself know where they have been transmitted thither from the decidua and the reflexa. The explanation is clear that the so-called lamina of inclusion is not continuous, this depending on the arrival or non-arrival at the chorion of the wall of the enlarged vessel resembling the lacunae. It is no longer necessary, in order to understand the formation of these last, to have recourse to the hypothesis that the villi, in proliferating, corrode the maternal tissue and the walls of the vessels, determining a sort of physiological hemorrhage. There is reason for the internal divisions of the placenta being constituted of two plates, although they spring from one uniform and continuous stratum. It could not be otherwise, since they represent the walls of two adjacent enlarged vessels, furnished on their external surface with the decidual elements which these vessels elaborate.

There is also reason for the manner in which are formed the so-called roots of attachment, the discovery of which has been erroneously attributed to Langhans.

In short, the author shows that, by substituting the observation of the neo-formative process of the decidua for the imaginary doctrine of the pre-existing mucous membrane, and that by following the formative process of the placenta from its first to its second phase of development, not only are all the uncertainties and all the errors avoided, which are generally taught at this time, but there is acquired a simple and clear acquaintance with the histological structure of an organ so important, not merely in woman, but also in all the mammifera.

As to the human placenta, it may be said that the chief difficulty of the question is contained in the opinion held upon the nature of the external clothing of the fetal villi in the placenta at term. According to the author, this investment is supplied to the villi from the mother.

By Kolliker, such an assertion is not even to be discussed, because the fetal villi are covered with a peculiar epithelium from the first moments of their development.

Apropos of this are shown the striking differences of form and size between the true fetal epithelium clothing the villi during the first period of development in the human placenta, and the covering shown by the same villi when the placenta has completed its phases of development, thus, for the most part, overthrowing Kolliker’s reasoning.

But the clearest and most convincing proofs for confirming the conclusions of the author are drawn from the observations made in the field of comparative pathological anatomy, which form the subject of his third and last letter.

In this, he strengthens with these observations the opinions offered upon the intimate normal structure of the placenta in the mammifera, as well as in woman.

For the mammifera, he described the maternal portion of the placenta at the close of pregnancy in the uterus of a female Myoxus glis (dormouse), in which part of the organ continued to develop in three segments, besides the two which were full, notwithstanding that in the said three the embryos had died at the beginning of the pregnancy, the fetal part of the organ had been necessarily arrested in its development, and that part atrophied which was developed before the embryos died.

Professor Cesare Belluzzi furnished the material for an analogous observation obtained in a woman who was delivered of a nine-months placenta, to which was united, by an atrophied cord, a small shrunken embryo, of about the size of the human fetus in the second month of intra-uterine life. The examination of the fetal villi in this placenta showed that the parenchyma of the villi was atrophied, and here and there changed by a chalky, granular degeneration, and that the so-called external epithelium of the villi was notably enlarged by hypertrophy and hyperplasia of its cellular elements. Since it would be absurd to believe that certain elements of a dead part might not only live, but be prolific, this observation furnishes an evident demonstration that in this woman were repeated the conditions found in the Myoxus glis, viz.: that the maternal part of the placenta had continued to develop after the death of the embryo, and that, consequently, the hypertrophic covering of the fetal villi can be maternal only, and not fetal.

The examination made by the author of two human placentas that remained in the uterus after parturition “at term,” the one for two, the other for three months, offered a favorable opportunity to make comparison with the aforesaid observation, and to exhibit the differences met with in conditions that may be styled analogous: when the maternal part of the placenta overruns its ordinary phases of development, and when the life in it is maintained beyond the ordinary term by an accidental cause.

For proof that the exterior covering of the fetal villi is furnished by the endothelial walls of the placental vessels, and by an external stratum of the decidual cells elaborated from their walls, the author records his observations, largely confirmed by Professor Romiti and others. Such observations are not difficult to make in examining villi of placenta of human abortions, in which, through the alteration of the parts that determine the abortion, a state is kept stationary,
which is only transitory in the normal condition—that is, the persistence of the chorial epithelium of the villus, although it may be surrounded by the maternal covering which remains separate from it.

To complete, from the pathological point of view, the observations and the conclusions reached upon the intimate structure of the human placenta, the author describes the anatomical lesions observed in a syphilitic placentum at term, in which he follows the process of infiltration of lymphatic cells, and of complete mucous or colloid degeneration in the portion called by Kölliker caducia of the placenta, and which, by universal consent, exclusively appertains to the mother. The same pathological process is followed by the author in the so-called epithelium of the villi in woman; and he observes how this process of infiltration of new elements, and subsequent colloid degeneration, which determines a swelling of the external wrapper of the villi, has been by learned writers designated by the improper name of deforming hypertrophy of the villi.

His labor thus ended, the author turns to the illustrous anatomist to whom he has addressed his letters, confident in the belief that he will at least concede that he has not been prompted by a selfish personality in thus controverting his views taught upon this subject, but that, the rather, he was drawn to it by the love of truth, and that, after long and repeated investigations, he has felt bound to obey the first duty of inquirers, whether great or humble—namely, to act in the best way possible to them for the discovery and promotion of truth.

THE PATHOLOGY OF
ACUTE LOBAR PNEUMONIA
FROM A NEW STANDPOINT.

By WILLIAM D. SCHUYLER, M. D.

First Article.

An Introductory Summary of the Diverse Views held by Leading Authors as to the Nature of the Disease; its Various Manifestations; its Unexplained Phenomena; its Importance; the Necessity of Accurate Pathological Data for Therapeutical Indications.

The absence of a settled general opinion relative to the well-recognized disease acute pneumonia, its obscure pathogenesis, as conceded and generally regarded, the universal prevalence of the disease and its destructive results, combined to render it a subject of deepest interest to the medical student, whether pathologist or clinician.

The diversity manifested by the disease in different individuals, in the degree of its symptoms, in its course and development, and in the mode of its resolution; the sudden termination of its symptoms when the process is at its height, as determined by the symptoms less the physical signs; the want of a constant relation between the constitutional symptoms and the extent of the local process; the manifestation of unexplained phenomena in regard to the most common site of the affection, i. e., in certain portions of the lung; in regard to pathological results, especially the non-injurious character of the process upon the pulmonary structure, the unexplained vascular conditions throughout the process, the rationale of the occurrence of crisis, and the unexplained phenomena of its temperature curve; besides other facts which relate to its blood conditions, to exudation, to nutrition, and especially excretion—increase and deepen this interest. Furthermore, the existing difference of belief and teaching among prominent and accredited authors as to its true nature or essential character as a pathological process; some holding to the old belief that it is a local disease merely, with its consequent and attendant general symptoms; others arguing with equal or more force that it is a constitutional affection—an infectious febrile disease with a local lesion; and others, undetermined, finding in both theories given points which they support and others which they reject. This difference of authority more than anything else enhances the importance of the subject and justifies investigation, however divergent from the generally received views the conclusions may be.

To define the nature of this malady which has been the object of much study, many essays and discussions; to show that its true character is specifically different from what it has been held to be historically, and that later as well as early teachings regarding it are untenable and inadequate to form a basis upon which may be constructed a rational plan for the treatment of the malady; to point out what I conceive to be the cause of and the initial lesion in the process; and especially to characterize the initial lesion, and show how all subsequent phenomena are but a natural sequence of it as it occurs—in a word, to suggest a broad basis of settlement for the character of the disease upon which all of its phenomena can be explained, to point out more clearly the dangers which attend the process, and to indicate a rational treatment for the same, is the object of this paper.

To initiate a departure from views which are historical and farther sanctioned and established by the authorities of our own time; to take issue with beliefs and dogmas seemingly well grounded by microscopical research, sanction, and support, is no easy task, and is one which I should not presume to undertake did not my own convictions, a sense of duty, and the claims of scientific truth, impel me to it.

That acute lobar pneumonia is a disease well worthy of most careful study, and that any truths which may be evolved thereby merit fair and honest scrutiny, whatever their source, is evident from its very serious character, which can not be over-estimated, from its general prevalence throughout the habitable world, and from its disastrous effects upon persons of all ages and all conditions of life, and such a study especially commends itself to medical men at this time for its more recent effects during the past winter in taking from our midst many useful lives.

From a clinical point of view, any light thrown upon this pathological process which shall define its scope, which limits and explains its different events, which more clearly interprets its symptoms and fixes the relation of the constitutional signs to the different movements and events of the local affection, which clearly specifies the dangers which may arise and traces them to their true cause, and which
shall point out the various indications for a rational treatment, should be most thankfully received. I may remark here that the practical scope of this work has especial regard to the latter reference to treatment. That there is need for therapeutic light in the management of this malady, that the treatment of acute lobar pneumonia has been, and is yet, most empirical, one must conclude from a general survey of the remedies used and plans resorted to, tried, and applauded, rejected and again advocated. Venesection, tartar emetic, salines, salines with stimulants, veratrum, aconite, digitalis, sweating, cold inhaled, cold externally, packing, sedatives and stimulants, treatment by quinine, expectant treatment, and rational treatment, so called, have each had their day, and each still has its advocates. The list given, considered with regard to the therapeutical effect of each remedy, is its own commentary, and clearly exhibits the blind groping and the absence of anything like an inductive method governing the means used. I do not mean to be understood as condemning a single remedy included in the above list. Each is valuable if rightly used according to a proper indication, but each is equally potent to do harm according to its activity or inertness if wrongly administered. This is what I would point out, that remedies work both ways, and that in no disease may a potent drug do more harm than in the process we are about to study. The indiscriminate use of remedies, therefore, is what we should deplore and strive to correct; especially as we exhibit them in a process so readily affected, so full of peril, and which, on account of some mistake, may in any stage prove fatal in a few hours.

We can not be prepared to exercise judgment in the management of a diseased process until we appreciate its true character—the nature of the action set up, its etiology, the significance of its symptoms and course, and the results of the morbid action or its inherent dangers. Until we have such complete knowledge of the disease from which to derive indications for treatment, we are more or less at sea, and in so far our therapeutics is both empirical and unscientific, if not positively dangerous or harmful. That we have as yet no well-grounded notions of the nature and true character of acute pneumonia may be inferred from what has already been said, and will be more clearly pointed out as we proceed; that we are in doubt as to the significance and cause of certain symptoms and phenomena, and also that the dangers which may arise are not well appreciated, will also be shown.

As setting forth, in brief, some of the uncertainties which are entertained relative to the disease, I give the following: 1. There is the general uncertainty, already specified, as to the true or essential character of the action set up, or of the nature of the entire disease. 2. Its pathogenesis is involved in obscurity, and its immediate cause is uncertain. 3. The tendency of the local affection to involve by preference certain portions of the lungs, the lower lobes, and the lower lobe of the right lung, in a majority of cases, is unexplained. 4. Many of its symptoms are not satisfactorily accounted for; notably, the cause of dyspnea or of the greatly increased rapidity of the respiratory movements. 5. The cause of the phenomena of resolution by crisis, the natural mode, and a most remarkable event, has not as yet been given. 6. There are sub judice questions as to the origin of exudation or some of its constituents, as to the condition of the affected vessels throughout the course of the process, and as to the febrile signification. Furthermore, as before noticed, the relation of the general symptoms to the local affection, and a seeming want of conformity of the former to the latter, is to be explained.

In the articles to follow, want of space and the desire not to be needlessly prolix and wearisome render it both impossible and impolitic to give even a partial reference to the many theories, views, and discussions which are extant relative to the subject under consideration. But, with the least that can be said for the end in view, a consideration of the entire subject of pneumonia will be somewhat extended, and, as this work is necessarily of the nature of an argument, fullness or completeness must be given upon doubtful points. However, so far as the writer's art will avail him, brevity will be studied. The functions and forces involved, the effects of the process in deranging the former and creating degrees of morbid development in the latter, and the action of events to produce morbid effects at one stage and conservative effects at another, render the subject, from a scientific and dynamic point of view—though intricate and difficult of portrayal—yet very interesting.

Book Notices.

The United States Dispensatory has always been an indispensible work to pharmacists, and far more adapted to be of service to practitioners of medicine than those who have not familiarized themselves with it would be likely to imagine. The fifteenth edition has been brought into accord with the new pharmacopoeia, and in many other ways the work has been amplified and improved. It would be strange if so large a book, embodying so much new work as this edition does, were wholly free from points open to criticism. We have observed several, but we will mention only two. The first is a tendency to relevant and unnecessary comments from a therapeutical point of view, as exemplified in the remarks on pulsatilla. The second is an occasional forgetfulness that the book is liable to be followed literally by persons who are incapable of digesting its contents. An instance is to be found in what is said of the treatment of phosphorus poisoning with sulphate of copper. The unqualified advice, "Sulphate of copper, with opium to restrain the emesis, should be administered in such doses as the stomach will retain," seems questionable in a work of this sort. Such defects as these, however, are trifling in comparison with the sterling value of the therapeutical part of the book as a
The editors have certainly done their work well, and this latest edition can scarcely fail to maintain the status of the dispensary with physicians and pharmacists.

This book bears a striking general resemblance in its appearance to the pharmacopoeia itself. Although professedly a companion to that work, its chief excellence, we think, lies in the short supplementary section devoted to non-pharmacopoeial drugs. The information it conveys is for the most part exceedingly fragmentary. Nevertheless, those who are entirely ignorant of materia medica and therapeutics can learn something from it.

Having been a member of the committee that prepared the pharmacopoeia, although, as he tells us in the preface, prevented from taking an active part in the work of revision, the author of this book, it might be supposed, would have become imbued with the spirit that animated the committee; yet in some respects his production is quite opposed to that spirit. The committee set itself rigidly against a nomenclature that confounded the alkaloids with neutral principles. It also discarded the absurd names ending in *ia* that have so commonly been applied to the alkaloids. The committee's course in regard to these matters was eminently wise, but Dr. Eves disregards it again and again in the book. Besides this evidence of carelessness for we can not look upon it as significant of a deliberate intention to thwart the good influence of the pharmacopoeia, we would remark upon the many inaccuracies in the French and German equivalents of the pharmacopoeial names of drugs.

**An Index of the Practice of Medicine.** By Wesley M. Carpenter, M. D., Assistant Pathologist to Bellevue Hospital, etc. New York: William Wood & Co., 1883. Pp. 304. [Interleaved.—Pocket cover.]

This little work is entitled to rank far above the compends of which there is such a surplus. Although modestly put forth, it is evidently not a mere compilation, but shows method and mature thought on the author's part. With the exception of syphilis and skin affections, it gives a condensed picture of all the ordinary diseases, together with succinct hints for their management. Dr. Carpenter is one of the few who, like the late Dr. Tanner, have the faculty of telling the reader in few words just what he is most likely to need to be told. The form in which the volume is brought out, with a flap cover for the pocket, was a happy idea, for we know of no book that a busy practitioner would find it more profitable to carry about with him in his daily rounds, to be taken out and read at odd moments, or studied on long, lonely drives.

**BOOKS AND PAMPHLETS RECEIVED.**

Experimental Researches on the Tension of the Vocal Bands. (a)—The Action of the Thyro-erisoid Muscle. (b)—The Action of the Expiratory Blast of Air. By F. H. Hooper, M. D., Boston, Assistant Physician to the Clinic for Diseases of the Throat, Massachusetts General Hospital, etc. Pp. 20.

The Stuart Period from a Medical Standpoint. By R. L. Macdonnell, B. A., M. D. [Reprint from the "Canada Medical and Surgical Journal."

Official Register of the Dentists of Iowa who registered as having been in practice prior to March 8, 1882, and those to whom licenses have been issued by the Iowa Board of Examiners. Revised and corrected to June, 1883. Published by authority of the Board of Examiners. Also Dental Directory of Missouri, Minnesota, Kansas, Nebraska, Texas, and the Territories, 1883.

**Note on Disinfectants.** In the "British Medical Journal" Dr. W. E. Buck writes: Most practitioners must have often realized the inefficiency of disinfectants in allaying the feter of cancerous ulcers, an annoyance which sometimes troubles patients even more than the pain, or the thought of death. I have used the whole round of disinfectants for cancerous ulcers, but all have failed in allaying the feter and keeping the ulcer clean. The disinfectants tried were carbolic acid, nitric, terebene, resorcin, creosote, boroglyceride, chloride of zinc, charcoal, etc. After failure with these, I tried a saturated solution of hypo-sulphite of soda added to an equal quantity of water, and found it exceedingly efficacious. The ulcerating surface was well sprinkled and washed with the solution, and was then covered with rags steeped in it. The granulations were kept clean, and the feter was well kept under. Most disinfectants seem to lose their virtue after a few days' application, but I have used this one for months in the same patient with continuous good effects. It is cleanly, has no smell, does not stain, and is very cheap.
THE PROPOSED STATE MEDICAL EXAMINING BOARD.

While there can be but little doubt that the Legislature of the State of New York will before long give serious consideration to the matter of creating a State examining board as a sole licensing body, and still less doubt that the establishment of such a board will be favored by the great majority of the profession, it cannot be denied that the advantages to be gained by the people and by the profession from the enforcement of such a scheme will depend upon points of detail concerning which opinions do not yet seem to be settled.

One of the first questions to be determined seems to be, as to who are to be affected by the board's action. It seems to us that all legally qualified practitioners living within the State at the time the act goes into effect should be exempt from its operation. Of course, such exemption will render the elevation of the tone of the profession that is looked for as a consequence of the measure slower of accomplishment than would otherwise be the case. It is better, however, that immediate and striking results should fail to take place than that individual rights should be invaded. But it is to this extent only that leniency seems desirable. All physicians coming from beyond the limits of the State for the purpose of engaging in practice should be required to undergo a bona fide examination by the board, no matter what their fame or achievements may have been, or what diploma they may have. Any other course would be unjust to our own colleges and to their graduates.

As to the constitution of the board, it should unquestionably be a body of men charged with the work of examining and licensing, and with nothing else. It will not do to put so much labor and responsibility on any board existing for other purposes. In some of the States, it is true, a function very much the same in kind has been given to sanitary boards, and it can not be denied that, in two conspicuous instances at least, those of Illinois and West Virginia, the State Board of Health has acquitted itself creditably. But it should be borne in mind that what work of this kind is done by those boards has reference only to persons who are in an exceptional position as regards their professional status, and not at all to the annual recruits from the colleges, for the diplomas granted by the latter still constitute so many licenses to practice. Moreover, State boards of health are constituted with special reference to the sanitary work required by the community, and there is no guarantee that their personnel will at all times be such as to fit them to act satisfactorily as examining and licensing bodies on so large a scale as the policy under consideration would call for. There is, indeed, little probability of its being of that character at any time.

If the board is established at all, it will be for the good of the people primarily, and for that of the profession only incidentally. The Legislature will therefore, doubtless, insist that the medical sects recognized by the State shall be represented. We can not see that this will do any particular harm if it is properly managed. It is useless, however, to expect good of a pro rata representation. There is no ostensible conflict between the rival sects in medicine, save in the single field of therapeutics. It seems necessary, then, that there should be three separate examiners in this department—one for the non-dogmatists, one for the homeopathists, and one for the so-called eclectics. In all the other branches there should be but one examiner for each, and in no instance should he be chosen from the ranks of the sects. We shall certainly be justified in insisting on the predominance of legitimate medicine to this full extent, and, while it will be our duty to obey whatever law may be enacted, and to do our best to make its operation as satisfactory as possible, we shall be culpable if we fail in any lawful endeavor to resist the encroachments of the sects beyond the point mentioned.

Perhaps the most knotty point of all to decide is, as to the mode in which the examiners shall be appointed. No better plan seems to suggest itself than for the Medical Society of the State of New York to appoint a full corps, and for each of the two analogous sectarian societies to designate an examiner in therapeutics. But, even if this course were determined on, questions of detail would still arise. It would have to be settled, for instance, whether teachers of medicine should be excluded from the board, and that question might either be decided by the law, or left to the determination of the societies. It would probably be politic, if nothing else, to exclude them. The tenure of office is not a consideration of the first magnitude, but it would be well to provide for overlapping terms, rather than a complete change at stated times.

The board should be a large one, examining in many more branches than the college faculties, and representing all the recognized departments of medicine. It is a question if it should not be a double one, to facilitate its holding sessions in various parts of the State. If this is not thought necessary, there should certainly be alternates appointed in each branch, to guard against inefficiency from causes affecting individual members.

Although the board should be the sole licensing body, it is questionable if it ought to issue its own diploma. It would doubtless tend more to promote a continuance of the desirable feeling of attachment that exists between the several colleges and their graduates, if the board's license were simply affixed to the college diploma in the form of a confirmation.

All these matters, and perhaps others of equal importance, should be well considered by the medical profession in the State, for it is quite probable that the Legislature will take action before long, and it behooves us to exert our influence to make that action as wise as may be. It will not do to lay rival schemes before the law-making body. To accomplish anything, the profession must know what it wants, and its wishes
must be expressed definitely and in such a way as to afford no reasonable pretext for hunters of mares' nests to pose before the public with the air of having ferreted out an attempt on the part of the regular profession to strangle the sects.

LIFE INSURANCE AND THE PERILS OF CHILDBIRTH.

When an accused person is conceded to have proved an alibi, and then goes on to offer corroborative testimony of his innocence, he is apt to put himself in the attitude of the dame who, when charged with having broken a pot she had borrowed, declared that the pot was cracked when she got it, and then added that she had never had it. This reflection is suggested by the pains that seem to have been taken of late by the officers of some of our life insurance companies to fortify their denial of certain motives said to have been attributed to them by Dr. W. A. Hammond as lying at the bottom of their unwillingness to insure the lives of women—as if their bare statement were not likely to be accepted by the public.

Dr. Hammond's allegation is understood to have been, that the reputation of the sex for inaccuracy was such that the companies felt it unsafe to rely on their answers to the questions put to them by the medical examiners. The gentlemen of the insurance companies aver that this is not the case, but that they are perfectly willing to insure the lives of women at a trifle in excess of their ordinary rates, that excess being rendered necessary, in their opinion, by the increased mortality due to childbearing among women who are below the age at which that function ceases. They add, that for insuring women past the menopause they charge no more than for insuring men of the same age. One of them remarks that the childbed mortality is very moderate in the civilized countries of Europe, being the lowest of all in France, but that in this country it is "frightful."

Now, let us look into the matter a little. The most trustworthy estimates are to the effect that, in Great Britain, in round numbers, one labor in every hundred gives rise to the mother's death. Dr. Lusk, who has investigated the matter with extreme carefulness, tells us, in his "Science and Art of Midwifery," that, according to the New York Board of Health's statistics for a term of years, the proportion in this city is about one to eighty-five. It is only fair to add that he says "at least" one to eighty-five. Assuming that the Board of Health's statistics are correct, this difference is certainly one to challenge attention and to occasion regret, but not, with any just appreciation of the force of words, one sufficient to warrant our friends of the insurance companies in calling the puerperal mortality of the country "frightful." Nor is it fair to make the New York mortality the basis of a calculation for the whole country. The general death rate of New York is high, as is well known, although not actually so high as the figures always make it appear; and that fact of itself would vitiate any estimate of the puerperal mortality of the country at large founded on those figures. Moreover, the total childbed mortality of this city includes the deaths of an enormous proportion of women of foreign birth, many of whom are rachitic or in various other ways predisposed to severe complications of the process of childbearing—a class, be it noted, with which the life insurance companies can scarcely have much to do.

The companies understand their business thoroughly, and there is nothing to show that they fall into the error of hampering its extension by the imposition of unnecessary increments of rate. It may well be conceded that they have sufficient reason for demanding higher rates from women than from men; but this is by no means equivalent to admitting that the perils of childbed are of themselves enough to constitute that reason. At all events, those perils cannot be said to be "frightful."

THE NEW QUARANTINE STATION ON CHESAPEAKE BAY.

Whatever uncertainty may be felt as to the strict legality of the Secretary of the Treasury's assumption that the lapse of an Act of Congress substituting the authority of the National Board of Health for that of the Surgeon-General has virtually revived the latter, there can be no other feeling than that of gratification at one of the immediate results of the Secretary's course, namely, the establishment of a quarantine station at the mouth of Chesapeake Bay. Certain it is, at all events, that those who live on the banks of the Susquehanna, the Patapsco, the James, or the Potomac, will not be in haste to criticise the Government for massing its quarantine operations in the neighborhood of Cape Charles and Cape Henry, rather than adhering to the more costly and far less efficient system always hitherto employed of dividing the work between the waters of Norfolk, Baltimore, and other ports on the arms of the bay.

Surgeon-General Hamilton, of the Marine-Hospital Service, has now an opportunity, such as is seldom afforded a medical man, to demonstrate before the whole country the necessity and the value of an enlightened and energetic central sanitary administration. Coupled with that opportunity there is, of course, a grave responsibility. We may well believe that Dr. Hamilton appreciates both the one and the other. Bound, on the one hand, to an efficient and at the same time economical use of a limited special fund, applicable to the work of staying the progress of epidemic diseases on internal lines of communication, and charged, on the other hand, with all that the National Government can do to the same purpose on the coast, the course of the Surgeon-General needs to be guided by sound judgment and discretion, as well as impelled by energy. Strengthened as his hands are now by the prominence of a threatened visitation of yellow fever in the public mind, the danger is that, when the first wholesome dread is over, the demands of trade will cease to find a check in that popular support that the administration of sanitary measures always needs. That the Surgeon-General will prove himself equal to such a contingency there is every reason to trust, judging from his admirable course thus far. It must be said that nothing could more encourage confidence than this action on Chesapeake Bay. It seems safe to assume that we shall not soon again be told of a yellow-fever ship having made her way into the harbor of Baltimore unmolested.
THE AMERICAN NATIONAL ASSOCIATION OF THE RED CROSS.

Small as the chance may be of our suffering to any serious extent this summer either from cholera, from yellow fever, or from some other pestilential disease, such a contingency is not by any means so remote as to excite a lukewarm regard for any measure of preparation designed to mitigate the distress that is always unavoidable as the result of an epidemic visitation. It is satisfactory to know, therefore, that we have in this country an organization acting under the auspices of the Geneva Convention. Thanks to Miss Clara Barton, whose tact and perseverance finally succeeded in inducing this "government of the people, by the people, and for the people" to condescend to allow its citizens to share the benefits of the confederation of Red Cross societies, we are now in a position, should occasion arise, to profit by the machinery of relief made ready, we can not doubt, by the American society.

Fortunately, warfare within our borders has not called for the relief measures it contemplates. It was our last war, however, and in particular the admirable work of our Sanitary Commission, that was largely instrumental in drawing the attention of the humane promoters of the Geneva Convention to the good that such an organization might accomplish. It is but fitting, then, that our people should first feel its practical working under other calamities than those involved in an armed contest. Our expectation that neither cholera nor yellow fever will obtain a foothold in the United States this season may at any time be shown to have been over-sanguine. Should such a state of things come upon us, and any of our large cities find its industries paralyzed and its sanitary resources crippled, the knowledge that the medical and nursing corps of the Red Cross can promptly be brought into play, as well as its stores of supplies, its provisions for hospital work, and its ambulance service, to say nothing of food, medicine, and money, will tend powerfully to counteract any tendency to panic.

MINOR PARAGRAPHS.

YELLOW FEVER.

Or the two diseases, yellow fever and cholera, it looks as if we were in more danger at present of an outbreak of the former. Up to the present time, however, the country has remained free from it, although vessels from Vera Cruz continue to land sick passengers at Havana, and in some instances to proceed to American ports. Information having been received from our consul at Vera Cruz in regard to the sailing of certain infected ships, but without mention of their destination, that officer has been directed to furnish more specific information on that point in future communications.

On Thursday of last week a seaman died of yellow fever at the Philadelphia Lazaretto station. He had come from Havana on a brig, which, it is stated, will probably be detained at the station for a period of three weeks. The steamship California, from Vera Cruz, arrived at Baltimore on Friday of last week, having had four deaths from the disease during the voyage. Several of her company were still sick with it. The vessel was at once quarantined.

Stimulated, perhaps, by this occurrence, together with the apprehension expressed by the people of Norfolk and Ports-
baled at ports this side of the infected localities, and where there is no suspicion that the disease prevails. It is believed that this article of commerce is frequently shipped from the ports referred to to European ports, where competition in freights is so considerable as to make it profitable to reship to this port. Consignees or owners of such cargoes will be required to furnish satisfactory evidence that rags reshipped from such ports have been cleansed, disinfected, and rebaled at the port of transshipment.

THE SANITARY CONDITION OF PHILADELPHIA.

At a meeting of the Philadelphia Board of Health, held on Friday of last week, General Kinsey offered the following:

Whereas, The sanitary condition of the city is not what it should be, particularly those portions bordering on the Delaware and Schuylkill Rivers; therefore, it is

Resolved, That the Sanitary Committee are hereby directed to cause a thorough sanitary inspection to be made of all market-places, wharves, docks, yards, courts, alleys, cellars, cesspools, and other places where filth is liable to accumulate and cause the spread of disease.

Resolved, That, to enable the Committee to carry out the first resolution, the Sanitary Committee be authorized to employ such additional assistance as may be necessary to make the inspection thorough and the work complete, all to be reported to the board and subject to their approval.

The resolutions were adopted. The Lazaretto physician, Dr. Robinson, reported that a brig which was detained at Quarantine with yellow fever on board had been thoroughly fumigated, and her crew were now in good health.

Dr. Richardson, who stated that a vessel laden with rags was on her way to Philadelphia from an Italian port, offered the following:

Resolved, That the special attention of the Quarantine officials be called to the transportation of Italian and Egyptian rags, in which it is possible that germs of cholera may be concealed, and thus enter this city.

This resolution also was adopted, together with another ordering that for the remainder of the quarantine season none of the Lazaretto officials should leave the station without the board's permission.

THE BOSTON CITY HOSPITAL.

In the annual report of the Board of Trustees, submitted to the Board of Aldermen on Monday of this week, it is stated that the net cost of maintaining the hospital has been $7,702.01 more than last year. This has been mainly due to the higher cost of subsistence and general supplies, and was anticipated. The excessive outlay incident to the care of the sick does not allow retribution, without lowering the standard heretofore maintained. The expense is considerably below that of several other general hospitals, and can not well be diminished without being directly felt by the sick. Among other recommendations, the trustees name more ample accommodations for treating patients with infectious or contagious disease by isolation. The want of such room has caused the rejection of a large number, sometimes under conditions that were a hardship to the patient, or the friends, as well as a danger to the public health. The trustees express regret that the city council has not granted their repeated request for an appropriation with which to build a pavilion for nurses. This is the sixth year that mention has been made of it. The want of a suitable building has been the cause of much ill-health and inconvenience among the nurses; it would have supplied rooms for fifty more patients, and would have provided for the isolation of delirious patients, and those very ill or dying, who now can, as a rule, be provided for only in associate wards. While the City Hospital is, and has been, foremost in many of the cardinal points of a good hospital, it is said to be far behind most others in its accommodations for those who nurse the sick.

"EVAPORATED" MILK.

The Granulated Milk Company, which has a factory at Walton, in Delaware County, and a warehouse in New York, is said to be engaged in experiments with machinery and processes designed to reduce milk to the form of a powder. While thus engaged, it condenses milk by the process of evaporation, transports the product to town, adds water to the amount of loss, and sells the mixture, thus saving freight on a bulky commodity. On some occasions, more milk having been contracted for than could be treated to advantage in this way, the cream has been skimmed off and disposed of to makers of ice-cream, and the residue, skim-milk, has been sold to farmers to be fed to pigs and other domestic animals. This is the company's story. Some of the Board of Health's milk inspectors, however, have suspected that the skim-milk was condensed by evaporation, and then offered for sale as "whole" milk, and in consequence of this suspicion the officers of the company were summoned to appear before a Police Justice last week, on a charge of violating the sanitary code. The company professes to be able to give satisfactory assurances that it has not pursued the course with which it is charged.

THE BRITISH PASSENGER STEAMSHIP MEDICAL SERVICE.

Last week a deputation from the British Medical Association, together with several members of Parliament, called upon the President of the Board of Trade and asked him to appoint a committee to consider the inadequate medical and sanitary management of Atlantic steamers. They commented upon the want of proper precautions on emigrant vessels, in consequence of which a large annual sacrifice of life resulted. They suggested that shipowners be compelled to increase the pay of ship surgeons, and that our Government be requested to contribute a small sum toward the expenses of vaccinating passengers. The President is said to have replied that he intended to introduce into Parliament in 1884 a bill dealing with the subjects mentioned and amending the Shipping Act.

THE AMBULANCE SERVICE IN JERSEY CITY.

Without undertaking to decide upon the merits of the case, we give the following statement from one of the newspapers: An Italian railroad laborer was struck by a locomotive Saturday afternoon and both legs were cut off. The injured man was brought to Jersey City in a train, and a telephone message was sent to the City Hospital for an ambulance. The authorities at the hospital asked what the case was, and, on being informed that a man's legs had been cut off, they demanded further particulars. Word was sent back from the railroad depot to send the ambulance down first, and then all the particulars that might be required would be furnished. This was refused, and the dispute was continued at intervals for three hours and a half. In the mean time the wounded man was lying in the depot. The ambulance was finally sent at half past nine o'clock.

SICKNESS AMONG HORSES IN CONNECTICUT.

Last week we recorded an outbreak of pulmonary disease among horses in West Hartford. It now appears that within the past few weeks sixteen horses have died in Stamford from a disease which results in paralysis of the throat and hind parts.
The animal, it is said, crouches like a dog, is unable to stand, and soon becomes bloated and dies, after a few days' suffering, from exhaustion. Dr. Tanner, a veterinary physician, thinks that the disease is chargeable to atmospheric changes, and warns owners against fast driving and against watering horses while in a heated condition. The dissections show an inflamed condition of the intestines.

A NEW CASE OF COW-POX IN FRANCE.

A milkmaid at Eysines having lately contracted a pustular eruption on her upper lip, the physician whom she consulted called the attention of the Bordeaux vaccination authorities to its nature. These gentlemen took some of the contents of certain pustules that they found on the teats of the cows on the place, and with it they inoculated a heifer in their parc vaccinal. The result was a lesion of tardy development, but supposed to be vaccinal. From it a second animal was inoculated, and undoubted cow-pox was the consequence. The Bordeaux Vaccine Institution therefore considers itself the possessor of an independent stock of cow-pox, although the criticism has been suggested that the punctures made experimentally may have become inoculated by accident, as the animals were allowed to run together promiscuously in the park.

A SUIT TO OBTAIN A DIPLOMA.

The "Maryland Medical Journal" gives the outline of the facts in a suit lately brought against the faculty of the College of Physicians and Surgeons, of Baltimore, by a gentleman who came up for the degree in the class of 1883, but was among the rejected. It seems that he petitioned a court to issue a mandamus ordering the faculty to give him a diploma—on what ground, we are not informed. The faculty filed a demurrer setting forth that it had the right to withhold its diploma on any ground it saw fit to take: that in such a matter its action was not subject to judicial revision. The demurrer having been sustained, the case has been taken to the Court of Appeals.

CREMATION AND THE CHOLERA.

In view of the possibility of a European outbreak of cholera, the "Progres medical" urges upon the authorities in Paris the importance of establishing crematories in three of the chief cemeteries of that city.

NEWS ITEMS.

The Riberti Prize.—The Royal Academy of Medicine, of Turin, says the "Gazetta degli Ospitali," has given the Riberti prize of 20,000 lire to Professor Giulio Bizozero, of the University of Turin, for the host essay on physio-pathology of the blood. Besides other Italians, the competitors included several distinguished English and French professors.

Mr. Jonathan Hutchinson, F.R.S., the "British Medical Journal" learns, is about to retire from the position of Senior Surgeon to the London Hospital, his term of office having expired. He has been appointed Emeritus Professor of Surgery in the Medical School, and will deliver a course of lectures on surgery each session. A "Hutchinson Testimonial" was resolved upon at a recent meeting of the present and former students of the school.

M. Pasteur's Pension has been increased, says the "Lancet," from 12,000 to 22,000 francs, with reversion to his wife and children, the bill having passed the French Chamber without a division. In reply to certain dissentients, M. Paul Bert cited the English grant to Jenner, and scouted the charge of sordid motives brought against Pasteur.

M. Pasteur's Cholera Commission, to proceed to Egypt, will consist, it is said, of M. Roux and M. Thuillier, of M. Pasteur's laboratory; M. Strauss, of the Faculty of Medicine; and M. Nolaco.

DARTMOUTH MEDICAL COLLEGE.—The address introductory to the regular course of lectures was given on Wednesday by Professor Louis Elsberg, of New York.

THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY.—Dr. W. T. Sedgwick, of the Johns Hopkins University, has accepted the chair of biology at the Institute of Technology.

THE CARNBY HOSPITAL, BOSTON.—An entertainment was given in aid of the hospital on Thursday at Forest Garden.

THE MEATH HOSPITAL, DUBLIN, has been obliged to discontinue the use of one third of its beds for a time, according to the "British Medical Journal," for lack of funds.

THE LOUISVILLE MEDICAL NEWS.—Dr. L. S. McMurtry has retired from the "News," and has been succeeded by Dr. H. A. Cottell, formerly an editor of that journal.

GLANDERS IN NEW JERSEY.—Health Physician Mandeville is reported to have found sixteen cases of glanders recently among the horses used on the Newark and South Orange horse railroad. It is said that the horses have been watered at public fountains.

A DISEASE AMONG CATTLE IN NEW HAMPSHIRE.—Seven deaths are reported as having taken place recently among cattle in the town of Stoddard, of a disease concerning which our only information is, that it proves fatal in from twenty-four to forty-eight hours.

MEDICAL EXAMINERS IN CONNECTICUT.—The corps appointed under the new law has lately been increased by the choice of Dr. W. S. Hulbert, of Winsted, for the towns of Winchester and Colebrook.

MARKED.—At Cincinnati, O., July 26, 1883, by the Rev. Dr. Rowland, Professor Samuel G. Armor, of the Long Island College Hospital, Brooklyn, N. Y., to Mary T. Yorke, of Cincinnati.

OBITUARY NOTES.

M. AROHAMBLET, OF PARIS.—The French journals announce the decease of this distinguished physician, who was well known in this country by his contributions to the literature of the diseases of children. He was a physician to the Hôpital des Enfants, and, like his master, Tronseau, was exceptionally successful with the operation of tracheotomy. His death was occasioned by a long and painful illness.

PROFESSOR FILHOI, OF TOULOUSE.—The death is announced of M. Filhol, the Director of the Medical School of Toulouse.

Dr. JAMES BALDWIN, OF DANBURY, CONN., died recently, at the age of eighty-one. He retired from practice a few years ago.

BERNARD G. SEMIG, M.D., ASSISTANT SURGEON UNITED STATES ARMY.—Surgeon Semig died suddenly in San Francisco, on Wednesday, the 1st inst. He entered the army as Hospital Steward May 20, 1863, was discharged June 27, 1864, and appointed Medical Cadet July 2, 1864, serving in that capacity until May 5, 1865. November 10, 1874, he received his commission as First Lieutenant and Assistant Surgeon, and five years later was promoted to the rank of Captain. Surgeon Semig had a brilliant record. He lost a leg during the war with the Modoces.
Proceedings of Societies.

AMERICAN OPHTHALMOLOGICAL SOCIETY.

(Supplement from page 102.)

Sympathetic Neuro-Retinitis occurring during Pregnancy.—Dr. McKay also reported this case. The patient was twenty-six years of age, and had been married ten months. In infancy she had scarlet fever, since which time the right eye had been weak. Five years ago the eye was treated for a painful inflammation by an oculist in Philadelphia, but during the last two years it had not annoyed her. When Dr. McKay saw her the eye was in a quiescent state of chronic irido-choroiditis, with partially occluded pupil and dense opacity of the vitreous. She complained of her left eye, and reported that after a week's crocheting a sudden pain was felt in it while looking at a white wall. She was debilitated by malarial and pulmonary troubles, and was three months advanced in pregnancy. Ophthalmoscopic examination revealed hypermetropia and a faint opacity of the deep portion of the vitreous, with decided congestion of the optic disc and retina. Within two weeks sympathetic neuro-retinitis was fully manifested, and vision was reduced to the ability to count fingers six to eight inches off in a dimly lighted room. After three months' treatment in a darkened room, with a dark bandage over her eyes, and the occasional use of a solution of atropine to prevent iritic adhesions, inunctions of mercurial ointment to the temples, several leechings to the left temple, and a general sustaining and tonic treatment, she improved in general health, the vitreous opacity as well as the exudation of the optic nerve and retina disappeared, and she recovered good vision. Her pregnancy, Dr. McKay thought, greatly modified the course of the sympathetic neuritis favorably. The ophthalmoscopic appearances of retinitis albuminuria were looked for repeatedly, but never found, and the fact of her vision not being again impaired while she had general anemia, which developed later in the progress of the case, made him regard it as a case of neuro-retinitis.

The Difficulties in Making a Differential Diagnosis in Glaucoma.—Dr. L. Howe, of Buffalo, read a brief paper and presented a specimen. The patient was four months old. When first seen, at two months of age, a yellowish reflex in the interior of the eye, which had been previously somewhat reddened, and vision, so far as could be determined, was much impaired. Increase of tension was scarcely perceptible, but after some hesitation it was regarded as +1. After enucleation, it was found that the entire vitreous had contracted into a small cone as a result of previous inflammation, and that the apex touched the retina, having its interior filled with a semi-purulent yellowish substance.

Commotio Retinæ; or some of the Effects of Direct and Indirect Blows to the Eye.—Dr. E. E. Holt, of Portland, Me., read a paper in which he reported four cases. In two of these the patient was struck more or less directly by a stick of wood, in one by a round rod or cane, and in the other by a flat piece of coal, striking the forehead, nose, and cheek, not hitting the eye itself. In three cases recovery was uninterrupted. In one there was a relapse. Vision was reduced to a perception of light for four days, after which it began to return, and in the course of two weeks became nearly normal. Relapse then occurred and vision sank, but not so low as it had been after the receipt of the injury. Recovery with a perfect eye took place much more slowly than at first. Dr. Holt gave a detailed history of this case, and also of one of the others.

The President remarked that Dr. Holt had reported four cases manifestly dissimilar in character. From a thorough study of the affection referred to, he had become convinced that commotio retinae was a phenomenon which had been entirely explained upon the supposition of a fissure running through the optic foramen of the orbit, and was almost entirely a mythical supposition by itself.

Dr. Selyea thought the subject could not be dismissed so summarily as Dr. Noyes had supposed. He had reported one case which could not be explained away so readily, because a single application of electricity restored a vast amount of vision, and there was no explanation of the extreme lowering of the vision from which the patient suffered.

The paper was further discussed by Dr. Kipp, Dr. Greening, Dr. Knapp, Dr. Wadsworth, and Dr. McKay.

Two Cases of Ophthalmoplegia Externa, Associated with Disease of the Optic Nerves from Brain Tumor, with an Account of the Post-mortem Examination.—A paper with this title, by Dr. Charles Stedman Bull, of New York, was read by title, and referred to the Committee on Publication. [Dr. Bull's paper will be given in a subsequent number of the journal.]

Injury to the Eyes by Hanging.—Dr. F. B. Loring, of Washington, said that since the series of experiments reported by Dr. Dyer he had seen no communications concerning the effect produced upon the eyes by hanging, except the case reported by Dr. Green, of St. Louis, which was not corroborative. He had had an opportunity to observe one case, which he wished to place upon record. In that instance both eyes were affected, but the one not so markedly as the other.

Dr. Green remarked that his case was not corroborative of Dr. Dyer's conclusions in a certain sense; but he did not consider it valuable either as corroborative or otherwise, because the time afforded for examination after the execution was too short, not being more than one hour.

Dr. Howr referred to one case in which he examined the eye thirty-five minutes after the execution, and was unable to see any change.

Dr. R. H. Derry referred to three cases which he had already reported in which there were marked changes in the eye produced by hanging.

Coloboma of the Choroid.—Dr. McKay, of Wilmington, wished to place upon record three cases. In one there was coloboma of the iris. Two cases occurred in children, aged, respectively, seven and ten months. The other occurred in a woman twenty-eight years of age. In the child seven months of age coloboma of the iris occurred.

An Improved Bandage.—Dr. Theobald, of Baltimore, presented an additional modification of his bandage, which he regarded as a substantial improvement. It consisted in cutting the eye-piece "bias," in order to prevent the tendency to wrinkling.

Powders for Application to the Eye.—Dr. Mittendorf called attention to a new method of applying remedies to the eye, namely, in the form of impalpable powders or triturations. He presented several specimens of remedies prepared in this way.

The President remarked that he had employed homatropine prepared in this way, and had been well pleased with the preparation.

Dr. Jones asked if this method was preferable to the discs prepared by Savory and Moore.

The Permanence of Eserine Solutions.—Dr. Wadsworth spoke of the loss of power in solutions of eserine. Recently he had found a solution which was three years old, and it still worked perfectly well.

Dr. Selyea, of Cincinnati, said that for ordinary purposes he preferred an old solution of eserine to a fresh one.
NEW YORK SOCIETY OF GERMAN PHYSICIANS.

A stated meeting was held October 27, 1882, Dr. F. Serr in the chair.

REMOVAL OF AN ANEURYSMAL TUMOR OF THE ORBIT.—Dr. H. Knapp presented a specimen of aneurysmal tumor of the orbit, recently removed by operation from a female patient who, eight years previously, had met with a fall, the consequence of which was a hemorrhage into the orbital cavity, followed by protrusion of the eyeball. The patient subsequently had severe headaches, and a circoid aneurysm had gradually developed over the whole left half of the head. Coincidently with the formation of cataract and the development of a high degree of exophthalmus, the eye had become almost completely blind during the past three years. Perception of light still remained. The patient also complained of very annoying noises in the ear. Two years ago Dr. Sands had ligated the carotid, securing primary union, and since then the noises had ceased, and the aneurysm had undergone a complete retrograde development. The exophthalmus, however, had not only persisted, but had increased, the cornea had sloughed, and the eye had been lost by panophthalmitis. At the inner canthus of the eye, and in both eyelids, a congeries of pulsating blood-vessels were visible. Two weeks ago Dr. Knapp had enucleated the eyeball without encountering any special difficulties, as he had been careful to keep close to the sclerotic and not to invade the orbit. On removal of the globe, the whole cavity of the orbit was found to be filled up with a pulsating mass, which imparted a firmly elastic resistance to the touch, and which sent out two prolongations—one to the upper and one to the lower lid. Since there were cases on record of the successful removal of similar growths from the orbital cavity, he had attempted extirpation in this case with entire success. He had opened into the orbital cavity at the outer angle, and penetrated along the roof until, reaching the apex of the space, a pulsating vessel of the size of the little finger was encountered, which, being compressed, caused all pulsation in the tumor to cease at once. The tumor was easily raised from its bed by means of fingers and scissors, and separated as far as its pedicle, only one vessel requiring ligature. The large vessel above mentioned, which constituted the pedicle of the tumor, was, after ligation, accidentally divided in front of the ligature, but, strange to say, not a drop of blood was observed to flow from the patulous mouth, which, as stated, had a caliber of the size of the little finger. The cavity was now lined by a gold-beater's skin, and filled with absorbent cotton. Healing took place, with complete asepsis, the secretion being merely serous. It was a very difficult matter to find a satisfactory explanation for the absence of hemorrhage from the central portion of the severed vessel. During the operation hemorrhage was avoided by his confining himself to working with the scissors, guided by the finger, between the capsule of the growth and the periosteal lining of the orbit. In answer to a query by Dr. Gerster, the speaker stated particularly that the periosteum had not been removed with the growth. Neither did he agree with that gentleman's suggestion, that, as ligation of the carotid had preceded the operation, there might be reason to suppose that the vessel contained in the pedicle of the tumor was a different and not an afferent one, so that the vessel had, in fact, been properly divided behind the ligature. The circumstance that compression of that vessel had cut off the blood supply and stopped the pulsation in the tumor was proof conclusive against the argument.

CAVERNOUS ANGIOmA OF THE TONGUE.—Dr. A. Frennder presented a case of cavernous angiomata of the tongue occurring in the person of a young married woman. The growth had originated in the shape of a small blue speck on the tongue when the patient was two years of age. It had grown slowly but steadily, being strictly confined to the median line, until it now occupied the whole left half of the organ, which was three times the size of the other half, of a dark-blue color, tense and elastic in feel, and easily emptied of its contents by compression. At the tip of the tongue the process had invaded the right half, and similar foci of telangiectatic development were discernible on the left half of the soft palate and on the buccal mucous membrane, extending forward as far as the first molar tooth. Two days before each menstrual epoch the patient had noticed an increase in the size of the tongue, always attended by slight dysphagia, until the flow was well established. At the left angle of the lower jaw an elastic swelling, the size of a small hen's egg, could be felt, easily diminished by pressure; this was evidently the root of the tongue, presenting the same condition as the rest of the organ. The speaker inquired whether ligation of the left lingual artery were not indicated as a means of cure?

Dr. Jacob said that, as the angiomata was supposed to be venous in character, he failed to see the benefit to be derived from ligation of the artery. In cases of cavernoma of the extremities, ligation of the principal afferent arteries had been found useless. If, in this case, the carotid had not already been ligated, he would suggest experimental compression of that vessel. Should this result in collapse of the swelling, it would then be eminently proper to apply the ligature. He would, however, recommend the destruction of the growth by puncture with needles at a black-red heat.

Dr. Guerek asked whether there was any direct indication requiring the removal of the tumor. He had had a patient, seventy-two years of age, the subject of a very similar growth, which had never given any trouble.

Herpes Zoster.—Dr. H. C. Klotz presented a portion of integument of the mammary region, removed from the body of a man who had succumbed to general tuberculosis two days previously. Shortly before death a crop of vesicles had made their appearance, attended by severe pain, in this region. Nervous influences were evidently concerned here, and the local process had not run its course when death had supervened.

Dr. Schiarlau showed a Fetus in the Fifth Week of Embryonic Development.

Litholapaxy.—Dr. Gerster showed the débris of a uric acid calculus weighing fifteen grammes, which had been removed at one sitting by Bigelow's method of litholapaxy. The patient, a man, fifty-three years of age, had been able to evacuate his bladder immediately after the operation, which had lasted about seventy minutes, had passed urine quite free from blood on the following day, and had been dismissed, cured, from the Mount Sinai Hospital, a week later. The stone showed a multinuclear structure. One of the fragments, of the size of a pea, had become lodged in the eye of the evacuating tube, requiring the temporary withdrawal of the instrument.

Blepharoplasty by Transplantation of Skin from the Arm.—Dr. E. Greening reported a case of blepharoplasty of the upper lid for ectropion, resulting from a burn, the flap for which had been entirely removed from the bicipital region of the arm. In accordance with a recommendation to select a flap two and a half times the size of the surface to be covered, he found his
flap almost twice as large as necessary. The preparation of the flap by the removal of all the subcutaneous adipose tissue was completed before severing its attachment to the limb. The transferred flap was not secured to the lid, but merely placed accurately in sitio, and covered with very fine gold-binder's skin.

Dr. Grester remarked that, as a general thing, it certainly was preferable in plastic operations to cut the flap too large rather than too small. A flap that was so small as to require any degree of tension to adjust it to the space intended for its reception was almost certain to slough, whereas the remaining portion of a flap that had been too liberally planned could readily be converted to further use. The speaker instanced the case of Wiencfeld, a patient at the German Hospital, from whom both eyelids, the eyeball, the orbital tissue, a large portion of the cheek and of the superior maxilla, and half of the nose, had been removed for epitheliomas involving these structures. The resulting ghastly deformity was relieved by bringing down two large curved flaps out of the integument of the forehead, one serving to construct the upper lid, the other for a partial rhinoplasty. When the flaps had firmly united, the redundant portions of integument were employed, one to form a partial covering for the defect in the forehead, and the other in the construction of the lower lid.

Dr. Schappinger remarked that the relative amount of shrinkage in flaps varied according to the age of the patient, and that, therefore, no general rule could be established.

Dr. Knapp was not enthusiastically in favor of the method. The results were not encouraging. In the majority of cases a flap that had had its connections severed would slough. The object in removing every particle of subcutaneous tissue from the flap was for the purpose of bringing the rete in direct contact with the denuded surface.

Dr. J. A. Wyeth reported a case of interest in connection with the subject, in which a flap measuring 7" by 2" had been prepared to cover a defect in the integument of the leg resulting from phlegmonous gangrene. The whole flap had sloughed. He recollected a case, occurring at the clinic of Professor Thiersch, in which the nutrition of the flap had been stimulated before complete removal by pinching the skin until hyperemia was developed. In this case, also, sloughing took place. When large flaps were employed, favorable results were exceptional.

A. G. Grester, M. D.,
Secretary.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held March 1, 1888, the President, R. A. Clemann, M. D., in the chair.

Double Enucleation of Uterine Fibroids.—Dr. W. Goodell presented the specimens and reported the case. Mrs. B., a Hebrew lady, aged thirty-eight, and the mother of five children, the youngest five years old, began, early in 1880, to have menorrhagia and difficult micturition. Afterward, her physician, Dr. A. H. McAdam, discovered a uterine fibroid. In January, 1881, Dr. Goodell was called in to see her. He confirmed the diagnosis, and found a fibroid in the anterior wall of the womb, bulging out the anterior lip of the cervix, which was greatly hypertrophied, but not at all enlarging the os. The sound gave a measurement of six inches. As all remedial measures wholly failed, he admitted her into his private hospital, and, on February 6th, cut into the tumor by means of Adams's subcutaneous saw, and by enucleation removed most of it. A month later the fragment left behind descended low enough to be removed without difficulty. The tumor weighed not quite two pounds. At the time of this last operation a small fibroid was discovered in the posterior wall of the womb, but it was too high up to be attacked.

Her convalescence was prompt, and her monthly flux became natural. On October 6th, the sound gave a measurement of only three inches, and she felt well. But in the following March she again sought his advice for a return of the menorrhagia. A fibroid was now bulging out the posterior lip of the cervix, not expanding the os. The uterine cavity measured five inches. As all remedies again failed, enucleation was once more proposed, and, on February 28, 1883, the operation was performed for the second time. The posterior lip of the cervix was cut open by the saw without invading the uterine cavity, and, after an hour's hard work, a tumor weighing one pound and a half was taken away in fragments. Several very beautiful and perfect fibroids, as large as a pigeon's egg, were also removed. They were attached to the capsule of the mother tumor merely by loose connective tissue. About a pint of blood was lost during the operation, but after the removal of the tumor the haemorrhage ceased, and the cavity left behind was not tamponed. The patient is doing very well, although the shock was somewhat profound.

In commenting upon this case, Dr. Goodell remarked that the to-and-fro linear movement of the saw made it a very efficient instrument for working in narrow channels, and that it had the further merit of lessening the amount of haemorrhage. He now used no other instrument for incising the capsule of fibroid tumors. The history of this unique case had somewhat shaken his confidence in the operation of enucleation, because, since the womb was affected usually with multiple fibroids, some one of these must invariably be left behind, and a second operation might become needful. He believed that in these cases oophorectomy, as a safer and surer remedy, had a future before it. He had, in fact, performed the operation four days ago on a lady who was so feeble from prolonged haemorrhage that he did not dare to remove the fibroid by enucleation, which was a more prolonged operation, and attended by a greater loss of blood. She was doing very well indeed. For the same reason, not daring to enucleate, he had early last year removed both ovaries for a bleeding fibroid, but after a remission of several months the haemorrhage returned, and he would probably have to perform enucleation or hysterectomy.

Dr. B. F. Baker inquired if the tumor in the case in which haemorrhage returned after oophorectomy was not of the submucous variety? Ought not the operation to be limited to the interstitial and subperitoneal varieties, where enucleation was not possible? In one case reported by Dr. Byford, of Chicago, a uterine (submucous) fibroid had gone on increasing, and hemorrhage had continued after oophorectomy.

Dr. Goodell, from a priori reasoning, would expect less favorable results in submucous tumors, as they were more like polypus in their character, and would be more likely to continue to bleed. The tumor referred to, for which oophorectomy had failed, was of the submucous type, and could have been removed by division of the mucous membrane and enucleation had the patient's condition permitted it.

Induction of Premature Labor for the Relief of Suppression of Urine.—Dr. B. F. Baker narrated the history of a case in which this procedure was considered necessary. The case occurred in the practice of Drs. Marcy and Meagor, of Cape May, N. J. About the sixth month of pregnancy a general edema was noticed, and the urine contained considerable albumin and a few casts. The amount of urine passed diminished rapidly while the proportion of albumin increased, and the patient became weak and anæmic. Every means was tried to increase the quantity of urine, but without avail. Among the remedies used were a wide range of diuretics and hydragogue cathartics, with Basham's mixture. A sudden suppression of urine occurred at eight months, and but four ounces were passed.
in forty-eight hours; this became solid when heated; headache and spots before the eyes were now added to the other symptoms, a gummos discharge from the uterine had been noticed for a week, and convulsions seemed threatening. Dr. Baer was called in consultation, and he agreed with them as to the advisability of inducing premature labor. A No. 9 flexible catheter was warmed and softened, and was, after great difficulty, introduced between the membranes and the anterior wall of the uterine. The cervix uteri had been lacerated in a previous labor, and was hard and small. Pains of a natural character followed immediately upon the introduction of the catheter. After some hours the pulse became weak and the patient faint, the os was but slightly opened, and it was considered advisable to administer stimulants, use Barnes's dilators, and the Hodge forceps; a dead child was speedily extracted. The latter had been alive in the morning. Four hours after delivery, urine was secreted, and in two days the albumin had entirely disappeared. The patient recovered.

**Induced Premature Labor for Great Edema of the Labia Minora.**—Dr. D. F. Willard reported the case of a patient, probably over forty years of age, who had been married about one year, and was pregnant with her first child. She suffered from headache, her feet and eyelids were swollen, and her urine showed a sixth albumin and contained casts and blood-corpuscles. Basham's mixture, diuretics of every kind, diaphoretics, hot-air baths, hydrogogue cathartics, and tonics were used without a satisfactory result. Digitalis infusion and jaborandi alone gave a very temporary relief. The patient, soon after her first visit, called attention to the condition of the labia minora, which were found to be enormously swollen, dry, sensitive, and pitting on pressure. The urine amounted to from fifteen to thirty ounces daily, and steadily decreased in quantity. The edema of other portions of the body decreased under the use of digitalis, but that of the labia increased. The patient could lie only upon her back with her knees drawn up and as widely extended as possible; the pain was great and constant; lancet punctures were made with temporary relief. The patient was steadily falling; her pulse was 150 per minute. An emollient, smooth muscle made its appearance and rapidly spread to the abdomen and thighs. Premature extraction of the child offered the only chance, and was at once performed. Gestation had reached eight months. It was a difficult task, as the labia were five inches in depth. Barnes's dilators and the Hodge forceps were used, and delivery was accomplished in two hours. The child was dead, and the mother died three hours later.

W. H. H. Githens, M. D., Secretary.

Reports on the Progress of Medicine.

**OBSTETRICS AND GYNECOLOGY.**

**BY ANDREW F. CURRIER, M. D.**

**Active Interference in Abortion.**—Spaldy's paper ("Ztschr. f. Geburtsh. u. Gynäk." ix, 1) is mainly a collection of fifty-three cases in which abortion occurred, in all of which there was a favorable issue. He offers nothing new, and only lays down those rules and precautions which every careful obstetrician would naturally follow. It is not a new idea, though a sound one, to recommend the complete removal of all the products of conception from the womb when an abortion has occurred. He thinks this can usually be done with the finger, in case the canal is sufficiently dilated to admit it. Hence the necessity of interference very soon after the foetus has been expelled, and of not waiting for the secondaries to come away without assistance.

**The Duration of Labor.**—Lumpe ("Centralb. f. Gynäk.," May 19, 1883; from "Arch. f. Gynäk.") says that in the calculation much depends upon fixing the time accurately when labor begins. Since there is so great a difference in the disposition as well as in the age and constitution of child-bearing women, it is hardly accurate to fix upon the first pains perceived subjectively as the beginning of labor in all cases. The condition of the cervix is a most important element in the calculation; indeed, the principal question is whether the cervix dilates before labor has begun. Two separate processes relating to the cervix are to be considered: 1. The opening of the cervical canal, which is the result of the so-called edema of pregnancy. Any sort of irritating process at any period of pregnancy may produce this opening, and complete closure may result without interruption of the pregnancy. Normally, the opening and moistening of the cervix, which end in dilatation, occupy from eight to fourteen of the last days of pregnancy. 2. The dilatation of the cervix, which can not be the simple consequence of the edema of pregnancy, but is always the result of uterine contractions. It leads, under all circumstances, to the termination of pregnancy. The author believes that a thorough knowledge of the physiological limits of labor, and particularly of its beginning, will prevent any unnecessary and premature interference with its normal progress.

**Cervico-vaginal Ruptures in Their Obstetrical and Forensic Significance.**—Bayer (ibid.) observes that incomplete ruptures of the uterus, rents of the cervix and vaginal wall, without involvement of the peritonaeum, are events which present great dissimilarities as to degree and as to significance. Two cases are reported, both occurring in multipara, in which the cervix was torn on the right side as far as the os internum, and the peritonæum was raised, but not torn, in a direction pointing toward the right kidney. Death followed in twelve hours in one case, from post-partum hemorragia; in the other, in two days, from sepsisemia. The raising of the peritonæum on the right side in these and in other reported cases is noteworthy, especially since the majority of ruptures of the cervix are upon the left side. In the first case, turning, and extraction with forceps, in a placenta prava patient had been practiced; in the second, the birth had been spontaneous in the normal position. The medical-legal question, in the author's mind, was based upon the hypothesis that the second case was also one of instrumental delivery. On this supposition, there would have been two identical accidents, both followed by a fatal result, and a fair inference would be that undue force or a lack of skill had been shown, which might have been a ground for prosecution. This was impossible, however, from the fact that there was no instrumental interference in the second case, and the fault in both cases might, therefore, be attributed, so far as the peeling up of the peritonæum was concerned, to anatomical peculiarities relating to the fixation of the pelvic peritonæum in its bed.

**The Treatment of Post-partum Hemorrhage.**—This note of Dr. Barnes's ("Lancet," Jan. 27, 1885) was suggested by a recent article by Mr. Coates on "Two Cases of Intra-venous Injections of Fluids for Severe Hemorrhage," in which it was shown that injections of simple water had no bad effect upon the blood globules. He approves of this method of treatment, but thinks that saline injections are better. It is especially necessary to have a good cannula. As might be expected, he has something to say in regard to the use of iron solutions for the arrest of post-partum hemorrhage. The principle which he insists upon is that, when the diastolic function of the heart is suspended, "persistence in remedies which act through that
function is useless, and may be injurious"; hence a local styptic action is desirable, and it is obtained from solutions of iron. He believes in strong solutions, but not in caustic ones, of the perchloride and persulphate, one to eight being the strength which he prefers. His concluding words are very valuable: "The first thing to do is to take care that the uterus is free from blood or clots. To insure this, a stream of hot water should first be sent through. This is a last appeal to the diastolic force. If it check the haemorrhage, the iron will not be used. But often it will fail; then the iron comes to the rescue as the last resource. About eight ounces should be injected slowly and gently. I have well weighed the advantage of swabbing, and prefer the method by injecting. With those who see no danger in haemorrhage, or who urge that it can always be checked by 'ordinary means,' it is useless to reason. Nor can the dictum that the remedy is worse than the disease command respect. Haemorrhage kills if not checked. It has often killed when the 'ordinary means' have failed."

**On Dangerous Haemorrhage from the External Genital Organs during and after Labor.—Dr. Peter Young's paper ("Edinburgh Med. Jour.," March, 1883) was read before the Edinburgh Obstetrical Society at the session of January 31, 1883. The author prefaced his remarks with the statement that dangerous or even fatal haemorrhage occasionally occurred after parturition, even when the womb was well contracted. This accident arose in such cases, not from the uterine sinuses, but from lacerations of the cervix or the external genitals. Two cases illustrating this point were given. In the first case the patient was practically lifeless when first seen, and all efforts to rouse her were ineffective. The autopsy showed that the uterine sinuses were effectively sealed with clots. There were several shots rents in the cervix. On the anterior wall of the vagina there was a tear five eighths of an inch long, which extended upward from the left side of the urethra to the left of the clitoris. The wound was seven eighths of an inch deep, of a spongy appearance, and revealed not only a divided plexus of veins, but some small arteries as well. In the other case the wound was also in the region of the vestibule. It was discovered seasonably, and the patient was saved. Wincell is quoted as to the possibility of injury to the nympha and labia majora during parturition, even without rupture of the perineum, but the neighborhood of the vestibule seems to be a more common, as well as a more dangerous, locality. The accident may be caused by the simple pressure of the child's head, especially if the tissues are friable, or otherwise without resisting power, or it may be caused by the interference of the accoucheur. As it is likely to occur when only the head of the child has been expelled, the existence of profuse haemorrhage at such a moment should suggest this accident. If, after ocular examination, it is found that it has taken place, it should be treated at once by pressure in the most convenient and suitable form which can be devised at the time. It will often be desirable to apply pressure temporarily, and subsequently pass one or more sutures through the wound.

**Psychogenic Hysteria.—Greller ("Centrallbl. f. Gynäk.," June 2, 1883; from "Arch. gén. de méd.,") thinks that the beginnings of hysteria antedate puberty in more cases than is commonly supposed; indeed, he thinks that menstruation has no real influence upon the development of the disease. The clinical picture of hysteria does not differ, whether the subjects are children or adults, both types presenting the same psychical phenomena, and the same sensory and motor disturbances. The usual ovarian symptoms, too, are not wanting in hysterical children, the trouble being referred to the left side. Whether these so-called "ovarian symptoms" have anything to do with the ovaries is to be questioned; at any rate, Kiefer reports the case of a twelve-year-old hysterical boy who had them well developed. The treatment recommended for these cases is hydrotherapeutics.

**Diseases of Gartner's Canals.—Böhm ("Zentralbl. f. Gynäk.," May 26, 1883) considers that a pathological interest attaches to those functionless remnants of fetal life, in that they may become diseased, either independently, or in connection with inflammations of the vagina, vulva, or urethra. This fact has been observed by him in a number of cases, the canals having undergone a sort of diverticular dilatation, while they were discharging a more or less abundant secretion, of the consistence of cream. The edge of the orificium urethrae also showed evidences of inflammation, as well as the gland-containing depressions in the mucous membrane surrounding that orifice. The treatment consisted in the application of astringent solutions, and in one case it was found necessary to divide the tissues. The trouble is likely to be confounded with gonorrhoea, especially when the canals open into the urethra.

**The State of the Uterine Mucous Membrane during Menstruation.—Besides Wyder ("Zchr. f. Geburtsh. u. Gynäk.," ix, 1), the names of Kündrat, Engelmann, Leopold, Möricke, and de Sinéty may be mentioned among those who have made investigations upon this subject. All of them agree that the uterus is deprived of its epithelium during menstruation, and is converted into a wound-like surface. The disagreement is as to the extent of the exfoliation. Williams concludes that there is a complete loss of the mucous membrane of the uterine body, and a laying-bare of the muscular tissue. Kündrat, Engelmann, Leopold, and the author are of the opinion that only the superficial layers of the mucous membrane are shed. The four authors first mentioned believe in a fatty degeneration of the menstrual mucous membrane, all but Leopold considering it as the primary and principal factor in producing the haemorrhage, while Leopold, on the other hand, considers it (the fatty degeneration) as secondary to and dependent upon the haemorrhage, the latter being caused by excessive dilatation of the capillaries of the uterine mucous membrane, with relative insufficiency of the veins. Regeneration takes place, according to the author, from the layers which have not been shed, and which are in a condition of cell hyperplasia. Neither Möricke nor de Sinéty admits that there is loss of mucous membrane during menstruation, or fatty degeneration, to a very great degree, the process being largely limited to congestion and dispepsis. The author proceeds to the analysis of eight cases, with special reference: 1. To the condition of the superficial and glandular (uterine) epithelium; 2. To the kind of haemorrhage which occurs during menstruation and the method of its occurrence; 3. To the condition of the mucous tissue, particularly the interglanular substance. He adds that Möricke gives the credit of having established the following points: 1. That during menstruation a portion of the mucous membrane of the body of the uterus is undisturbed; 2. That the teaching of Kündrat, Engelmann, and Williams concerning a primary fatty degeneration of the uterine mucous membrane is no longer tenable; 3. That the superficial and middle layers of this membrane do not suffer conversion into a decidua. His own views are summarized as follows: 1. During menstruation a portion of the superficial layer of the mucous membrane disappears, the rest remaining. This shedding process varies in extent in different cases, now involving the entire superficial layer (Leopold, Wyder), again taking only a small portion of it (Spieglerberg). The elements which are thrown off are partly detritus and partly undecomposed matter. In some cases, as in dysmenorrhea membranacea, small mucous shreds are found, which, however, are too small to cause dysmenorrhea. 2. This process of shedding is caused by the haemorrhage of menstruation, and not by primary fatty de-
generation. 3. The superficial and middle layers of the mucous membrane, which are left behind, show an abundance of small cells, but no similarity to the decidua membrane of pregnancy. The deepest layers show a cell-hyperplasia of the inter glandular tissue, the evident mission of which is to furnish a supply for the tissue which is lost during menstruation. 4. The degeneration of the superficial epithelium is participated in, as well by the glands as by the surrounding membrane in which they are embedded.

Manganese in the Treatment of Amenorrhoea.—Dr. S. Ringer and Dr. W. Murrell ("Lancet," Jan. 6, 1883) have been using permanganate of potash extensively, in hospital practice, for amenorrhoea, with good results. They have used it both in the pharmaceutical (B. P.) solution and in the form of one- or two-grain pills. One grain three times a day is given to begin with, and this is increased to two grains four times a day, the larger doses giving the best results. Its administration should be begun three or four days before the period is due, and, if it is not successful in bringing on the flow, its use should be continued for some time, even until the next period is due, if necessary. It should not be discontinued as soon as the flow appears, as its use will facilitate that process. Its action is not so certain in the case of girls who have never menstruated, though, after having been tried unsuccessfully, it may be successful if tried at a subsequent period. It is also recommended in the case of women who have reached middle life, have passed through numerous pregnancies, and have become irregular. It is necessary to avoid giving it during pregnancy for any cause, though it is not known that it will produce abortion. In the amenorrhoea of phthisis it is not thought to be of value. The pills will usually be found to be more acceptable to the patient, as to any disagreeable after-effect, than the solution. Permanganate of sodium and binoxide of manganese are equally effective with the permanganate of potash. Manganese does not seem to improve the condition of the blood in anaemia and chlorosis, but acts equally well with the plethoric and the anaemic.

Offensive Catamnetal Discharges.—Dr. Wiltshire ("Med. Times and Gaz.") remarks that menstrual discharges commonly have a peculiar but not an offensive odor, the former being due to the secretions of the glands around the vulva, the latter being an evidence of disease. Especially in the discharges of chlorotic women is this peculiarity noticeable, the blood of such people being readily subject to decomposition, and its greenish color being due to altered coloring material. The mechanical retention and decomposition of clots, in cases of stenosis or flexion, are also causes of putrid menstruation, and these may be added subinvolution. Still other cases are caused by some disease of the endometrium, often of a malignant character. Then is the time when a developing uterine cancer can be best treated. The general treatment for such a condition consists in the proper use of disinfecting astringent solutions.

Uterine Irritation and Uterine Movement.—Ronge ("Centralbl. f. Gynäk.," May 26, 1883) says that the value of hot water in producing uterine contraction being so well recognized, it occurred to him to make a series of experiments, in order to test also the efficiency of cold as an irritant to the uterus. Very young pups were selected for the experiments. The abdominal cavity was carefully opened, and the uteruses presented a pale-red appearance. Water at 5° C. was then poured into the cavity, covering the uteruses, which suddenly became rigid, and of a slightly deeper color. This tetanic condition lasted about a minute, after which the organ returned to its former condition, but manifested a few weak contractions. More water being added, so as to keep the uterus in a medium with a temperature of 5° C., the condition of contraction of that organ continued for ten to fifteen minutes; the color became a deeper red, the vessels dilated and filled with blood, while the muscular tissue became very pale. After half an hour the muscular tissue became redder and more relaxed, and the uterus returned to its normal condition. Further irritation being applied, of a mechanical, electrical, or thermal nature, marked uterine contractions followed, showing that the irritability of the organ bad not been exhausted by the action of the cold. Identical results followed the application of cold to the rectum. If the experiment was repeated at a temperature of 50° C. during a period of ten minutes, the uterus gradually became flaccid, and reddish-blue in color. Cold or electricity being then applied, the uterus showed no irritability. Even strychnine applied at this high temperature caused no contractions, or none of any force. The action of cold in these experiments, therefore, was to produce a long-continued and firm contraction of the uterus, with no intercurrent stage of paralyis; this stage was reached only when the temperature exceeded 40° C. If the same conditions obtain in man as in animals, this would seem to prove that cold is more effectual as a hemostatic than heat. In obstetric practice, while cold water would undoubtedly stop the haemorrhage in a patient anemic to the verge of collapse, it would precipitate the latter condition. Hence hot water is almost universally preferred in the exhausting hemorrhages of parturition. The author suggests, en passant, the very useful precaution against pain and accident, in the use of hot water, that the entrance to the vagina and the vulva be well smeared with carbolized oil. In gynecology, hot-water injections are certainly more grateful to the patient, and their power of producing absorption is far greater than that of the cold. Hence, whether cold or hot water is to be employed depends upon the exigencies of the case. Both act as irritants to the uterus, and will produce contractions.

Subinvolution of the Uterus.—Williams ("Brit. Med. Jour."") says that, by the investigations of Hesselt, who took a series of measurements of the uterus in the cases of women who had died at different periods after delivery, it was ascertained that the greatest loss of weight occurred in the second week after that event. There are elements of uncertainty in such methods of calculation which, the author thinks, can be remedied by the systematic measurement of the uterine cavity in the living subject with the sound, in connection with the bimanual method of examination. In one hundred and thirty cases in which he made examinations he found that there were ninety-six in which the uterus had contracted back again into the cavity of the pelvis on or before the twelfth day of the puerperium. The process of involution goes on more rapidly with young multiparas than with primiparas, and more rapidly with the latter class than with old multiparas. The duration of labor has no influence upon the process, but post-partum haemorrhage and retention of the secondaries have a bad influence, as does also rupture of the perineum. The author thinks that rupture or laceration of the cervix has no influence, good or bad, upon the process. In some cases of puerperal fever and pelvic peritonitis, involution is not interfered with, in others it is delayed. The influence of suckling and early getting-up is not yet decided in the author's mind, though he thinks the recumbent position well adapted for drainage, and approves of the use of disinfecting solutions as vaginal injections.

A Clinical Classification of Backward Displacements of the Uterus.—Dr. Herewau ("Lancet") remarks that backward displacements of the uterus occur chiefly in cases in which there is relaxation of the muscular tissue of the pelvic floor, and particularly among women who are inclined to inflammatory and other diseases of the pelvic organs. The uterus being displaced, the venous flow is obstructed, and the uterus then
becomes congested. The following classification is made: 1. Those cases in which the patients experience no discomfort, which, according to Vedeler's statistics, amount to about 16-49 per cent of all women. 2. Those in which the only symptoms are those of prolap—namely, pain in the region of the sacrum and bearing-down pains, trouble in urination, constipation, vaginal catarrh, occasionally, but no menstrual disturbances. With women who are thus affected, the symptoms disappear when they lie down, and mechanical treatment, by means of a pessary, is often signally successful. 3. Those in which congestion of the uterus has occurred, and the phenomena resulting from that condition include menstrual disturbances. If the congestion is the result of pressure upon the veins, due to backward displacement, the raising and antverting of the uterus with a pessary will produce a good effect. If, however, the congestion is only an accompagnement, or, it may be, the cause of the displacement, then a hard-rubber pessary will only increase the congestion; a soft-rubber ring will do much better service. 4. Those cases which are complicated with other diseases. In these, help is often afforded by means of a pessary, if the uterus is movable.

The Development of Uterine Myomas.—Kleinwächter ("Ztschr. f. Geburth. u. Gynäk.," ix, 1) thinks this process is not yet fully understood. Virchow's opinion is that an excessive enlargement of muscular fibers, as a rule, does not take place, but there is a conversion of round cells into spindle cells, and these cannot be distinguished from organic muscular fibers. The question remains as to whether the round cells are developed from the connective tissue or from divisions of the muscle cells. Förster believes in the division of the muscle cells, but admits the possibility that a new growth may proceed from connective tissue. According to Klebs, the formation of muscular tissue proceeds at a parallel rate with the development of vessels, and the consequent amount of abundant supply of nutrition. According to the author, the best specimens for the study of this subject are very small growths in which proliferation is actively progressing. In these pure myomata, or fibro-myomata, the connective tissue exceeds the organic muscular tissue to a greater or less extent. Pure fibromata were never found. The growths which have been met with by the author were mostly small subserous structures, and usually multiple. They were very often located upon the fundus, seldom upon the posterior wall or lower segment of the body, and only in exceptional cases upon its anterior wall. The peritoneum was apt to be thickened at those points where the growths projected. The breadth and length of the cells and nuclei in a myoma are commonly greater than in a normal, unipregnated uterus. Large arteries and veins were not often found in the small myomata, and the capillaries showed an abnormal relation; on both sides lay rows of round cells, which in many cases formed a kind of envelope. These seemed to assume by degrees a spindle shape, so that they quite resembled organic muscular fibers. In this transformation the capillary vessel disappered, and in its place appeard a bundle of muscular fibers. Each myoma showed a long, thin pedicle, which gradually became lost in the surrounding muscular tissue, and the question was suggested as to whether this was not originally a vessel, and the very one, too, from which the myoma began its development. In some tumors, capillary vessels in a normal condition were seen, as if the process of pathological development had ended, and so had caused an end to the development of muscular tissue. Commonly a myoma and a fibro-myoma were found side by side. Though the author never saw a new development of vessels in a myoma, in a fibro-myoma this process was observed. Also the transformation of round into spindle cells was not observed in the latter variety.

The Treatment of Uterine Cancer with Chin Turpentine.—Dr. E. Holland ("Brit. Med. Jour.," March 24, 1883) alludes to the introduction of this drug for the treatment of uterine cancer by Mr. Clay, of Birmingham, and the prejudice which has prevented a fair trial of it. He has used it in a series of cases in which the existence of the disease was doubted, and in which it had made considerable headway. After a fair and unbiased trial the conclusion was inevitable that it did no good; it neither relieved pain, nor prevented hemorrhage; when used upon the uterus it produced strangury, in some cases, and when used upon the breast it was prone to produce eczema. His opinion is that the only remedy which is as yet known for the disease is early and complete extirpation. Even in advanced cases operative measures are often justifiable for the temporary relief which can be obtained thereby.

The Pathological Anatomy of Tuberoulis of the Uterus and Fallopian Tubes.—Dr. J. L. Steven ("Glasgow Med. Jour.," Jan., 1885) observed this rare condition in the case of a woman twenty-four years of age. The lungs gave very little evidence of tuberculosis. The rectum was performed by an opening of the diameter of a quarter of a dollar, and this opening communicated with Douglas's pouch. In this vicinity caseous nodules were abundant both in the rectal mucous membrane and in the peritoneum of Douglas's pouch. They were also found in the mucous membrane of the cervix, in that of the cavity, and in the left Fallopian tube, which was thickened and elongated, discharged thick caseous material on section, and contained caseous, fatty masses. The right tube was involved to a lesser degree, and some of the contiguous lymphatic glands were implicated. There were also millary nodules at the base of the brain, in the region of the infundibulum. The specimens from the uterus and tubes were examined microscopically, and the tubercular bacillus was found, thus verifying the diagnosis from the gross appearance. The conclusions from this and a case which had previously come under the author's notice are: 1. Tuberculosis of the Fallopian tubes alone may arise from the action of infective material which has been drawn into them from the peritoneal cavity; 2. Tuberculosis of the internal female generative organs may be primary, and may remain most severe in them.

Obstetrical Operations.—Tauffer ("Ztschr. f. Geburth. u. Gynäk.," ix, 1) says that since Hagar and Battey proposed this operation it has been done more than three hundred times. He dissects from Battey's statements that an artificial climacteric is to be obtained, and that this is the means of cure. He considers that an anatomical change is the end accomplished—a diseased organ being removed, which is of first importance—the climacteric not being the end to be sought for in all cases in which the operation is required; for example, in a case of hopelessly prothused ovary. Hagar's formula is accepted by him—that castration is indicated in amonalous and diseased conditions which are immediately dangerous to life or promise only a tedious progressive sickness, obstructive alike to enjoyment and to occupation. This presupposes that instrumentilities of a milder nature have been used, or can only be used in vain, while the removal of the ovaries will do away with the trouble. Twelve patients have been operated upon by the author without a single death. These cases are grouped upon an anatomical basis, as proposed by Hagar, the groups including the following conditions: 1. A small parovarian cyst. 2. Cystic, follicular degeneration of the ovaries, with degeneration of the stroma. 3. Such a condition of the uterus as rendered menstruation impossible or very difficult, the ovaries, meantime, proving to be normal. 4. Structural disease of the uterus; e. g., myo-fibroma. 5. Pathological displacements of the uterus and ovaries. 6. Circum-uterine and circum-ovarian inflammation, inflammation of the pelvic con-
nective tissue, and salpingitis. 7. Mental disease connected with the family history. The following is the résumé of the cases: ten double, two single operations; no deaths; continuance of inflammation in tubes in two cases; immediate menopause in four; menopause after an apparently normal menstruation in one; metrorrhagia continued in two patients who had been operated upon for fibroma uteri. In three the periods continued normally for a number of months (while the patients were under observation), caused by inflammation of the tubes or of some other portion of the uterus or its attachments. The author sums up his experience in the following Propositions: 1. With proper precautions, castration is not attended with great danger; the average mortality is now less than ten per cent. 2. The operation should be done antiseptically, with the spray; the abdominal cavity should be closed; drainage need be employed only exceptionally. 3. The limitation of the operation to those who are not near the climacteric is not sound, for the period at which the climacteric occurs is variable. 4. The precept of Hegar's—to be able to palpate the ovaries, if they require removal—is impracticable. 5. It is usually best, for obvious reasons, to remove both ovaries, especially if one shows disease. 6. Occasionally the removal of the tubes is necessary, especially if they show the slightest disease. 7. Hysterectomy is totally curable by castration. 8. Hysteria is often traceable to ovarian disease. 9. The question as to the influence of ligation of certain large vessels of supply in uterine fibromata, without castration, is well worthy of consideration. 10. As to prognosis concerning the climacteric, all inflammation in organs adjoining the ovaries will have a retarding influence. 11. The final result of the operation often requires months for its determination. 12. The question as to how far diseases of the female sexual organs are influential in the development of certain psychoses is an open one. 13. The same is true of the question as to whether psychoses are curable by castration. 14. In the interest of the profession, some such grouping of cases should be followed as Hegar’s, thus permitting a rapid accumulation of facts necessary to one who is studying the clinical history of the subject.

**Miscellany.**

**The Use of Quinine in the Diseases of Children.**—M. Jules Simon, of Paris (“Revue des maladies de l’enfance,” February, 1883), calls attention to the necessity of being in mind the curious and unexpected forms in which malarial poison manifests itself in children no less than in adults. The obscurity of the malarial origin is often greater in cases affecting children than in those affecting the mature. Not only may there be no fever, but there may be no periodical exacerbations of the disease. There may be no reason to suspect the true nature of the attacks, except the history of exposure in a malarial region. Nevertheless, if the affection be due to malarial poison, all treatment that does not take the cause of the disease into consideration will signally fail, while quinine will effect the most astonishing cures. M. Simon cites four cases of children suffering from irregular forms of malaria, some of which had resisted all other treatment, all of which, however, yielded quickly to the sulphate of quinine.

**Perchloride of Iron in Diphtheria.**—M. E. Dinaud ("Union médicale," July 5, 1883) calls attention to the value of perchloride of iron in diphtheria, in which disease it should be used both internally and locally. He urges its use internally for the purpose of preventing the diphtheritic poison from modifying the composition of the blood. M. Regnard, when hospital internes under M. Jules Simon, performed the following experiment: Taking two specimens of blood, one from a patient who had succumbed to some other disease, he caused a current of oxygen to pass through each, separately. The blood from the non-diphtheritic subject quickly regained a bright red color, while that from the case of diphtheria remained of a dark color. He was thus led to believe that diphtheritic poison deprived the blood of its property of absorbing oxygen, probably by destroying the hemoglobin of the red corpuscles. And the efficacy of the perchloride of iron as a remedial agent in diphtheria he supposes to be due to the material it furnishes to their hemoglobin to the red corpuscles. The perchloride of iron may be given in a liquid form, two to six grammes being a suitable amount for a period of twenty-four hours. In some cases the dry salt is preferable. Dragées are now made, each representing four drops of the liquid perchloride. These may be given, one every two hours at first, and afterward one every hour. Thirty of the dragées are equivalent to six grammes of the liquid. As has been mentioned, this treatment should be combined with the local application of the iron to the diphtheritic patches.

**Influence of the Benzamid of Alkalies on the Excretion of Uric Acid.**—Edmund Alleyne Cook, L. R. C. P. Ed. ("British Medical Journal," July 5, 1883), has come to the conclusion, from a series of experiments, that the benzoates of the alkalies do not prevent the excretion of uric acid, as has been claimed by Dr. Garrod in a paper before the Royal Society. Dr. Cook's experiments, as interpreted by him, show that the benzoates, taken internally, do increase the solubility of uric acid, and prevent its precipitation by acidulation; but that the uric acid, instead of disappearing entirely, exists in a state of combination, perhaps as a compound acid. Other experiments by Dr. Cook confirm the view that the salts of potassium and of sodium, when present together in excess in the urine, have the power of destroying the uric acid present, probably by a process of oxidation, the products of its decomposition being oxaluric acid, and, finally, urea and oxalic acid.

**Seasickness: its Prevention and Relief.**—J. M. Kendall, L. R. C. P. Ed., of Sydney, Australia ("British Medical Journal," July 7, 1883), after observations in two hundred cases of seasickness, has come to the following conclusions: Food in sufficient quantity to keep the stomach comfortably full diminishes nausea, and prevents overstraining in retching. Soups, milk-puddings, and sweets should, however, be avoided, as they increase the tendency to sickness, and are followed by sickness, nausea. Curry is often retained by a stomach that will reject all other food. Oranges should be abstained from, and lemon-juice also, except in cases of extreme nausea. Brandy is to be used sparingly. It is useful in extreme prostration, but champagne is better. Champagne is a very popular remedy, but great prostration often follows its discontinuance. Bicarbonate of soda acts nicely in mild cases; in severe attacks it is worse than useless. Worcestershire sauce will often relieve disagreeable symptoms. Hydrochloric acid is seldom of service. If acidulated water is desired, it should be acidulated with hydrochloric acid; other acid mixtures should be avoided. Cressote is to be withheld in the early stages, but is often very useful in the later stages, to relieve excessive prostration. In Dr. Kendall's hands, bromide of sodium, ten grains three times a day, proved to be the most effectual of all remedies.

**Electricity as a Galactagogue.**—M. E. Labbé ("Union médicale," July 5, 1883) calls attention to the value of electricity as an adjuvant to other means for establishing or restoring the secretion of milk in puerperal women. When the secretion is absent or scanty, or when it has been suppressed from any cause, in addition to other modes of treatment (suction of the nipple, poultices of leaves of the Ricinus communis, etc.), it is well worth while to employ a weak current of electricity. The mammary gland is to be gently compressed between two electrodes consisting of moistened sponges. A mild current passed twice a day, for ten to fifteen minutes at a time, will materially increase the functional activity of the gland. (The author does not state whether he means the galvanic or the Faradic current.)

**Gallium Aparine for the Relief of Cancer.**—Dr. Charles Boyce, of Maidstone, Eng. ("British Medical Journal," July 7, 1883), believes that Gallium aparine may be used with benefit in cancer. It should be given internally and applied locally. The juice of the fresh plant,
expressed after macerating, should be given twice daily by the mouth, in five-ounce doses. The ulcer should be smeared at the same time with an ointment of the juice. Over the ointment freshly bruised leaves should be frequently applied. The diet must be simple, and the state of the bowels carefully attended to. This treatment, if persisted in, will gradually decrease the size of the ulcer and lessen the pain.

Cannabis Indica in Melancholia and Mental Depression with Sleeplessness.—Dr. William Strange, of Worcester, Eng. ("British Medical Journal," July 7, 1883), has observed beneficial results from the use of cannabis in cases of melancholia and mental depression attended with sleeplessness. The usual dose he thinks is too small; at least a grain of the extract or twenty to thirty minims of the tincture should be prescribed ordinarily. This amount, combined with half a drachm or a drachm of bromide of potassium, rarely fails to give relief. It dulls the anxiety, lessens the depression, and gives restfulness if not sleep. If there be visceral disturbance, hyoscyanus acts well with the cannabis. Dr. Strange reports an interesting case of accidental poisoning with cannabis. Nearly half a drachm of the spirituous extract was taken at one time. Three hours afterward the patient presented the following symptoms: There was superficial anæsthesia so complete that he felt as if he were dead. He declared he could not touch or recognize anything. All objects appeared in multiple. The action of all the senses was perverted. The pupils were dilated, but responded slightly to light. There was no clammy perspiration, no failure of the pulse, no sexual excitement. Vomiting did not occur until artificially induced. The dread of death was intense, and the facial expression indicated great fear. Brandy was used freely, and after two hours the patient fell into a deep sleep, from which he awoke the next morning with a ravishing appetite.

Very Dilute Solutions of Exsine in the Treatment of Weakness of the Ciliary Muscle.—Dr. John C. Uthoff, Surgeon to the Susses Eye Hospital ("British Medical Journal," July 1, 1883), has met with much success in the use of very weak solutions of exsine in cases of failure of accommodation. Two classes of patients, comprising no small proportion of all who resort to ophthalmic surgeons, are specially benefited by instillations of exsine in very dilute solutions. The first and chief class is that of young adults who are slightly hypermetropic, but who enjoy good vision until it is rendered defective by failure of general health, or by overtaxing the eyes with excessive near work. As the power of accommodation fails, the effort to do near work, especially by artificial light, causes headache, and such work can be performed for short periods only. The use of a weak solution of exsine (g. $\frac{1}{2}$ to $\frac{3}{4}$), dropped into the eye three times a day, is attended with great benefit, and may preserve the power of near vision at its normal standard until, with rest and improvement of the general health, the ciliary muscle regains its normal power. The second class of cases consists of patients suffering from masked myopia, who, even when supplied with proper glasses, are sometimes unable to use them with any comfort for near vision. The feeble power of accommodation of such myopic eyes may be greatly improved by weak solutions of exsine. In these two classes of cases instillations of a solution of g. $\frac{1}{2}$ to $\frac{3}{4}$, used three times a day, were attended in some cases with immediate benefit, the improvement continuing so long as the solution was used, and remaining for a varying period thereafter. In other cases the improvement was maintained only by increasing the strength of the solution. In a few cases—and in but few—no good results were produced by weak solutions. [Dr. Uthoff gives in detail the results of his interesting experiments with weak solutions of exsine on the pupil and ciliary muscle of the normal eye.]

The Illinois State Board of Health's Requirements of Medical Colleges.—At the last meeting of the board it was Resolved, That the Indiana Eclectic Medical College, of Indianapolis, Ind., and the Joplin Medical College, of Joplin, Mo., having given assurances of their intention and determination to fully carry out and abide by all the requirements considered by the Illinois State Board of Health as essential to the good standing of a medical college, the diplomas of said colleges will be recognized in the future by this board whenever and so long as it shall appear that their methods and practices entitle them to be classed among "medical institutions in good standing."

In a foot-note, the secretary adds: Although the language of this resolution explicitly says that these colleges will only be recognized as in good standing "whenever and so long as" their methods and practices entitle them to such recognition, the action of the board has been misinterpreted to be a direct and unconstitutional recognition of the Joplin and Indiana Eclectic. The resolution is not legitimately susceptible of any such construction, nor was it so intended by the board.

I have also answered letters inquiring whether the diplomas of certain colleges would be recognized in the future, in accordance with the spirit of this resolution, to wit, that recognition would depend upon a substantial and bona fide compliance with the board's requirements, both as to preliminary education and course of study.

Since the adoption of that resolution facts have come to my knowledge which do not encourage the belief that it will be possible to recognize the diplomas of the Joplin, at least, upon any assurances yet received. The announcements of this college contain, it is true, what is asked for in the matter of requirements for graduation, etc.; but the accompanying letters and documents, herewith submitted, demonstrate that a compliance with our standard of minimum requirements in this case will, to a great extent, be merely on paper. In the case of other colleges, additional instances of evasions of their own published requirements have come to my notice since our last meeting, and it involves upon the board to duly consider what weight shall attach to the paper promises and proclamations of remote schools.

To recognize or reject the diplomas of colleges upon the mere fact of their literal acceptance or non-acceptance of our published standard could not fail to work injustice in some instances. On the one hand, diplomas would be recognized which might be worthless as evidence of the real qualifications of their possessors, while, on the other hand, graduates of colleges whose general standing and character are vastly better might be rejected.

To rigidly adhere to such a rule would, in effect, be to discriminate against the schools of our own State; and yet our Illinois colleges, as a whole, do better work, furnish better facilities, and are more thorough in their instruction, than those of many other States. In point of fact, many of these latter should be entitled to recognition only as preparatory medical schools; since neither in the qualifications of their teachers, nor in their anatomical, physiological, or chemical laboratories do they possess such an equipment or furnish such facilities for instruction as to warrant them in conferring the degree of M. D. upon their students, with the popular estimation of the virtues which such a title now possesses. Further, such a course would virtually frustrate the object of the Medical Practice Act, by throwing open the State to any incompetent possessor of the diploma of an institution which had nominally complied with the minimum requirements for graduation of the State Board of Health. The obvious intent of the law is to guard the people from ignorant and incompetent medical practitioners, and it indicates the standard by which to judge of the fitness of claimants to the rights and privileges conferred by it.

In any effort to define this standard, by formulating the conditions which constitute the "good standing" of a medical college, it must be the substantial and bona fide, and not a superficial and perfunctory compliance with the essentials of a sound medical instruction which shall be the test. Such, of course, is the meaning and intent of the board in its adoption of the report of its Committee on Medical Education.

The Nature and Treatment of Diphtheria.—The "Therapeutic Gazette" thus summarizes the results of its "collective investigation" of diphtheria:

1. Diphtheria may be either local or constitutional in its origin.
2. It may continue as a purely local or as a purely constitutional disease, or the local disease may be followed by constitutional infection, or vice versa—the disease in the vast majority of instances manifesting itself in both the constitutional disturbance and the local affection.
3. The comparative value of local and constitutional remedies is dependent upon the nature of the affection in individual cases.

4. Diphtheria is a contagious disease, but not liable to attack a healthy mucous membrane or to find an entrance through it into the circulation.

5. The contagium of diphtheria is not a micrococcius, nor is it visible under the most powerful microscope yet manufactured.

6. The contagium of diphtheria is of a gaseous nature (the result of decomposing faecal and other organic matter), and can be neutralized only by a true disinfectant and not by an antiseptic.

7. The best local application is the tincture of the chloride of iron. It may be supplemented by other applications according to the indications in individual cases.

8. In a typical case of atheptic diphtheria, administer large (ten-grain) and frequently repeated (hourly) doses of calomel until the characteristic stools are secured. Following this, give large doses of the tincture of the chloride of iron every two hours, and administer alcohol within the limits of intoxication. In atheptic cases the calomel should be omitted and the main reliance placed on the iron and alcohol.

Charing-Cross Hospital.—For the purpose of undergoing cleaning and repairs, this hospital will be closed to in-patients from the present time to September 2d, and to out-patients until August 26th.

—Lancet.

Listerine.—Joseph Taber Johnson, M.D., says: "I have used Listerine in the same class of cases in which I have been accustomed to use carbolic acid, and have been much pleased with results. In uterine cases, and for removing odors from my hands after examinations, I employ it frequently. Its freedom from the peculiar odor of the carbolic acid is much in its favor. It is an excellent remedy, properly diluted, to correct the foul smells after abortion, and to disintegrate offensive lachrymal discharges. I often use it in obstetrical cases. In suppurative and catarrhal ulcers, and discharges in the throat and nasal passages, it promptly corrects the intolerable odor, and gives equal satisfaction in offensive leucorrhoea." Dr. George J. Engleman speaks highly of it in obstetrical and surgical practice.—Med. Annals.

A NEW METHOD OF APPLYING PRESSURE TO ENLARGED TESTICLES.

—Dr. J. L. Corbett, of Lackaw, writes in the "Lancet": "In the treatment of some of the diseases of the testicle accompanied with enlargement, the practice of applying pressure to the gland is undoubtedly a sound one, and is frequently resorted to by surgeons. I have often wondered that some simpler plan than that of strapping with plaster has not been suggested. The objections against the plaster strapping are numerous. First, it is a tedious business to do neatly and properly. Second, it is dirty both for operator and patient. Third, the operation has to be begun by incising the neck of the gland with a long strip of plaster. This undoubtedly interferes with the free circulation in the vessels of the cord, and tends to prevent the absorption of the material deposited in the gland. It stands to reason that the freer the circulation in the vessels going to or from the testicle, the more rapid will the reduction in size be from the operation of absorption induced by pressure. Fourth, the strapping loosens very rapidly, and, to be of use, must be reapplied frequently. Fifth, in many cases, even when carefully applied, the plaster cuts the skin and leads to sores. Sixth, I have seen many troublesome eruptions on the skin of the scrotum following the use of the plaster. I have, I think, enumerated enough objections to the old plan, and I will now try to explain the means I would recommend for obviating these objections, at the same time applying a steady, equal, compressing force, and one which would also admit of easy regulation as regards the amount of compression. I may preface the explanation of my plan by saying that I derived the idea from a homely source—nothing more nor less than seeing the means employed for incasing a football; barring that, instead of having the incasing material made of leather, I would have it made of India-rubber—such as one sees in the construction of the balls in spray-producers, etc. The cases I recommend should be made of different sizes and thicknesses, oval in shape (same shape as the Rugby football when inflated). The means of tightening the cases and applying the pressure would be identically the same as in the football cover—i.e., by lacing. There should be an opening at the neck of the case to allow the passage of the cord. This opening would be surrounded by a ring (interrupted) of leaden wire, to insure its patency and to prevent pressure on the structures of the cord. The leaden wire ring being interrupted, its softness would offer no obstacle to its easy adjustment round the neck of the enlarged gland. With a supply of the cases which I have attempted to describe above, the treatment of an enlarged testicle would offer but little difficulty; it would simply mean the selection of a rubber case of the right size and thickness, and capable, when laced up, of exercising a steady, equal pressure on the enlarged organs, and applying the case to the testicle and lacing it up. If considered necessary, the testicle could first be enveloped in a thin layer of cotton-wool; this would prevent any possibility of the skin being nipped or chafed by the lacing. As the gland reduces in size, a smaller case would be applied, and thus a steady pressure kept up until a cure was effected. The above plan has the advantages of simplicity, neatness, and quickness in its application to recommend it. It involves no elaborate apparatus, and I think does away with many, if not all, of the objections connected with the operation of strapping with plaster.

A SANITARY CONVENTION will be held at Muskegon, Mich., under the auspices of the State Board of Health, on Thursday and Friday, August 23 and 24, 1883. The objects of the convention are the presentation of facts, the comparison of views, and the discussion of methods relating to the prevention of sickness. At each session of the convention there will be addresses or papers on subjects of general interest pertaining to public health, each paper to be followed by a discussion of the subject treated. Reduced fare on railroads may be obtained by applying to the secretary of the convention, C. P. Done- son, M. D., Muskegon, Mich., for certificates.—Weekly Medical Review.

THE LEXINGTON MEDICAL ASSOCIATION will hold its third annual meeting at Easton, Pa., on Wednesday, the 15th inst. Dr. Traill Green, the president, will give an address of welcome; Dr. A. M. Coop- er, of Point Pleasant, will relate seven cases of strangulated hernia; and Dr. Charles K. Mills, of Philadelphia, will deliver the annual address, on The Diagnosis and Treatment of some Forms of Grave Byteria.

NAVY INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during week ending July 28, 1833.—Passed Assistant Surgeon J. D. Gatewood, detached from the New Hampshire, and ordered to hold himself in readiness for sea-service.—Assistant Surgeon Henderson, detached from the receiving ship Franklin, and ordered to the New Hampshire.—Assistant Surgeon Horace B. Scott, ordered to the receiving ship Franklin, Norfolk, Va.—Surgeon D. McMur- trie, detached from the receiving ship Franklin, and granted sick leave.—Passed Assistant Surgeon Robert Whiting, granted one month's leave.

ARMY INTELLIGENCE.—Official List of Changes of Officers serving in the Medical Department of the United States Army from July 21, 1832, to July 22, 1833.—Sutherland, Charles, Colonel and Surgeon, Medical Director Military Division of the Pacific; and Department of California. The leave of absence granted by S. O. 04, Headquarters Military Di- vision of the Pacific, June 30, 1833, is extended two months. S. O. 168, A. G. O., July 23, 1833, Bally, Joseph C., Major and Sur- geon. Assigned to duty as Post Surgeon at Fort Cohnco, Texas. S. O. 87, Headquarters Department of Texas, July 19, 1833, Appel, A. H., First Lieutenant and Assistant Surgeon. Granted leave of ab- sence for two months, with permission to apply for an extension of one month. S. O. 30, Headquarters Military Division of the Atlantic, July 20, 1833.

SOCIETY MEETINGS FOR THE COMING WEEK.—Tuesday, August 7th: Elena (N. Y.) Academy of Medicine; Buffalo Medical Association; Ogleensburg (N. Y.) Medical Association. Wednesday, August 8th: Medical Society of the County of Oswego, N. Y. Friday, August 10th: Medical Society of the Town of Saugerties, N. Y.
Lectures and Addresses.

A LECTURE ON
THE TREATMENT OF MENINGITIS.*

By Professor DuJardin-Beaunetz,
Physician to the Hospital St.-Antoine; Member of the Academy of Medicine, Paris.

Gentlemen: This lecture will be devoted to the treatment of inflammations of the meninges, with special reference to tuberculous meningitis. The latter is undoubtedly one of the most formidable diseases which you will ever be called upon to treat, and one of the most hopeless.

Inflammation of the meninges may affect different points; sometimes the membranes of the ecephalon alone are inflamed, sometimes those of the spinal cord, sometimes both simultaneously, constituting cerebral, spinal, and cerebrospinal meningitis, any one of which may be either acute or chronic.

I can not here trace for you the pathological history of these different meningites, and, as in previous lectures, I shall devote myself to treatment, beginning with the inflammations of the meninges of the cerebrum, the tuberculous form of which claims our first attention, by its frequency, its gravity, and its peculiar march, resulting as it does from the presence of tubercle granules in the encephalic envelopes.

From the special point of view with which we are concerned we have only to insist on these two points, the presence of tubercles, and the disorders which they occasion in the meninges and in the substance of the cerebrum, and ask ourselves if these lesions are curable and compatible with life. The curability of tuberculous meningitis is a question which has been much discussed of late years; it has been denied by some and asserted by others. The problem is a difficult one; it is so easy to confound the tuberculous phlegmasia in its acute manifestations with simple cerebral or fibropurulent meningitis, which only differs from the other in the absence of the specific granulations. Moreover, there are certain convulsive phenomena, of reflex nature, which may simulate inflammatory meningeal troubles. These former affections being curable, it is easy to understand that, when a mistake in diagnosis has been made, and the supposed tuberculous child recovers, the medical attendant would naturally claim a demonstration of the curability of the disease under consideration.

To-day this question is definitely decided, and the facts published by Archanbault, Roger, Blache, Bonamy, etc., justify the affirmation that the evolution of tubercles and the accidents of phlegmasia developed thereby may be arrested in their march. The proofs are of two kinds, the one furnished by pathological anatomy, the other by ophthalmoscopic examination.

As for the first class of proofs, we have the facts noted and reported by Roger, where a child recovers from a first attack of tuberculous meningitis to succumb to another, months or years afterward, and the autopsy reveals traces of the old phlegmasia and those of the new. As for the second class, you all know the importance of Bouchut's ophthalmoscopic studies in tubercular meningitis. The ocular examination with this instrument really enables us to make an autopsy before death by showing us the presence of tubercle granulations in the fundus oculi, so that, in an individual affected with meningitis, and presenting visible granulations in the choroid and retina, you may positively affirm the tuberculous nature of the meningeal inflammation; and, if the patient gets well, you have evidence of the curability of the disease. It was precisely this that happened to me in the case of the hospital patient which I reported to the Société des Hopitaux in 1878.*

This patient was a young man, twenty-three years of age, occupying No. 21 of Ward St. Lazare. He had presented all the symptoms of tuberculous meningitis; his father, a drunkard, had died of phthisis; his mother had died of phthisis following diabetes; the examination of the fundus oculi by Dr. Meyer, one of our most competent oculists, revealed neuro-retinitis and tubercles in the choroid; my diagnosis certainly seemed to be well founded. This young man, I assure you, recovered perfectly from his brain trouble, and for four months has not had a return of the disease.

Moreover, why should tuberculosi of the meninges follow a different course from tuberculosis in other serous membranes? Do we not see tuberculous pleuritics get well? The remarkable investigations of Grancher have made clear the tendencies to tuberculosis in many instances toward recovery; in others, however, the march is characterized by progressive fatal invasion. There is, then, gentlemen, no doubt of the possibility of the arrest of this disease, even when the membranes of the brain have undergone inflammation; and this consoling idea ought to direct all your efforts in the treatment of this grave affection. Of course, the chances of cure are lessened as the disease advances. Possible at the onset, recovery is exceptional when, by reason of the presence of tubercle granules in the meninges, inflammatory disorders have arisen, entailing profound lesions in the encephalon.

You know, in fact, that the pathological anatomy of tuberculous meningitis shows us, besides the granules, hanging from branches of the Sylvian artery like clusters of grapes, all degrees of phlegmasia from simple thickening of the membranes to the production of pus. We also see ramolissement of the peripheral cortical strata, and finally that intraventricular exudation and that softening of the fornix which have long characterized this disease, to which the name of acute hydrocephalus was early applied.

These different lesions have different symptoms, and you know that, from the standpoint of semeiology, tuberculous meningitis has been divided into several periods, corresponding to the various anatomo-pathological phases of the malady. In the first periods we observe only the symp-

* DuJardin-Beaumetz, "Tuberculous Meningitis: Arrest of the Disease; Recovery from all the Symptoms," "Union méd.," 1878.

* Translated, with Professor DuJardin-Bescametz's permission, by E. P. Hurd, M. D., Newburyport, Mass.
toms belonging to the evolution of tubercle granulations. In the later stages we see unfolded the complex phenomena which result from the inflammatory alterations determined in the brain and its membranes by the presence of the tubercles.

All our therapeutic efforts, as must now be apparent to you, ought to be directed toward preventing the production of these inflammatory manifestations, and, whatever may be our chances of success in the initial periods of the disease, those chances will be well nigh nil in the terminal periods. It is sufficient to add that prophylactic treatment ought to occupy the first place.

There is a fatal law which presides over the evolution of tubercles in different parts of the economy. I refer to the law of heredity, and tuberculous meningitis is no exception to this law. Therefore, we sometimes see all the children which spring from the union of tuberculous parents succumb successively to these first manifestations of tuberculosis, while the parents offer much longer resistance to the diathesis which they have transmitted to their offspring. Moreover, as there is a hereditary phthisis, an innate phthisis, and an acquired phthisis, so also it may be affirmed that there is a meningreal tuberculous corresponding to these three kinds of causes. If, as West has shown, in twenty-seven out of every forty-two cases of tuberculous meningitis this diathesis is found in the parentage, in other cases it is easy to trace the influence of two other important factors—bad health of the parents on the one hand, and faulty hygienic training of the children on the other.

The bad sanitary condition of the parents explains to us how alcoholism, diabetes, scrofula, excesses, cerebral troubles, disproportion in the ages of father and mother, etc., may be invoked as causes of tuberculous meningitis in the offspring. But we must also make great account of the bad hygienic conditions of the children. In our infant wards we find every day a striking confirmation of what I have just said. When in a little child we have diagnosed miliary granulations of the meninges, we always observe, as determining causes, either tuberculosis or alcoholic excesses in father or mother, or, in the case of the child, an infancy passed amid the most deplorable hygienic surroundings. Hence indications are plain enough from the point of view of prophylactic treatment.

In all families where you have occasion to apprehend the appearance of meningreal granulations, either because one of the children has already fallen a victim to the disease, or because the parental antecedents lead you to fear an outbreak of the kind, you ought to insist upon the utmost care in the rearing and education of the child. The tuberculous mother must not nurse her own infant; the child should, if possible, be brought up in the country and kept much in the open air; prolonged and fatiguing intellectual tasks must be strictly forbidden. By gymnastic exercises you should endeavor to establish a just equilibrium between the muscular functions and those of the cerebrospinal axis. By hydrotherapy you may calm the cerebral excitement of these young children, who almost always display a precocious intelligence. You should have a careful supervision of the food, and be ready to oppose the least disorder of the digestive organs, for here, as in the evolution of pulmonary tuberculosis, it is the failure of nutrition in general which predisposes to cerebral granulations.

You should, then, have a surveillance of all the periods of early life, with these two ends in view: to favor in every way the nutritive functions, and to avert excitation of the cerebro-spinal axis. I have said early life, for if the tuberculous brain affection oftener attacks children in the first years of their life (from three to six), it also finds its victims among youths between the ages of fifteen and twenty years.

But, unfortunately, you are not often called till the advanced periods of the disease, when the meningean inflammation has commenced its ravages. The prodromal periods have passed unnoticed, and the guardians of the child have placed to the account of peevish disposition, or to irritation of the digestive organs, the changed character of the child, the constipation, the vomiting, etc. When you are called in, meningitis is pronounced. What are you going to do? The treatment is the same whether the meningitis be tuberculous or simple.

The reulsive medication has been employed in all its rigor, and just as pleuritic, peritoneal, pericardial, articular inflammations have been treated by vesicatorys, so also the blisters have been applied to the shaven head of the hydrocephalic child. This reulsive treatment has been varied, and irritant inunctions have been advised with tartar emetic, or with croton oil; the actual cauterity has been recommended, and even the moxa.* These reulsive measures have been applied in all their rigor, not only to the shaven head, but also to different parts of the body, and in particular to the inner aspect of the thigh. Without absolutely denying the good effects of the reulsive medication in meningitis, it must be admitted that this method of treatment has been abused, and, for my part, I have more than once seen the condition of the patient rather aggravated than benefited by the irritation and pain provoked by severe vesication in this disease.

Therefore I warn you to be chary in the employment of these violent measures, and to prefer the constant application of ice to the head, which seems to me to have quite as much influence as the most energetic reulsion. If you resort to the ice-cap, it should be made to cover the whole head, and its application should be continuous. You may also make use of cold affusions to the head, as Schützenberger † advises, and, better still, the apparatus recommended by Dumontpellier, whereby a constant current of

---

* Hahn, of Aix-la-Chapelle, advocates tartar emetic ointment in meningitis. No internal medication, the shaved scalp to be rubbed every hour with the stibian ointment. Henriette, Turner, Watson, and Bang counsel inunctions of pure croton oil, first recommended by Henriette (of Brussels). Tracy, Valentin, Smith, and De Bellange prefer cauterieuse with the red-hot iron, while Billet and Barthez and Constant claim excellent results from the moxa. Bellange, of Brussels, reports a case of a child, aged three years, affected with meningitis who was cured by means of an issue of caustic potash on the top of the head.

† Schützenberger advises to place the child's head over a bucket at the edge of the bed, and to play upon it streams of water from a watering-pot ("Des affusions froides dans l'hydrocéphale aiguë").
cold water is maintained. The head should previously be shaved. To complete what I have said as to local treatment, it has been advised to leech the patient behind the ears; some, as Torci, have gone farther, and have proposed, not only bleeding from the temporal veins, but even abstraction of blood directly from the longitudinal sinus. [Torci opened this sinus from the anterior fontanelle, and withdrew eight ounces of blood. The child, a nursing infant, singularly enough, recovered, but nearly a month afterward succumbed to a second attack.] For my part, I am opposed to these emissions of blood in meningitis, and particularly in tuberculous meningitis; they weaken the child, without any sufficient compensatory advantage.

The internal treatment of meningitis comprises a great number of medicaments; unhappily, the very fact that the number is so great indicates how inefficacious, often, they all are. These medicaments may be ranged in several groups; some are directed to the phlegmasia, some to the symptoms which it produces, others especially to the tuberculous cause of the affection. Meningitis, considered as a simple inflammation, has been combated by the ordinary antiphlogistic treatment. Mercurials, and especially calomel, have been advised in small and often-repeated doses. This practice has received the sanction of Troussel, and at one time hardly a child was attacked with meningitis that was not mercu rialized to salivation. At the present day the calomel treatment is much in vogue, but the mercu rial is given in fractional doses. A grain of calomel is rubbed up with a drachm of white sugar, and divided into ten powders; of these, one powder is given every hour. Unfortunately, it is not proved that the mercurial medication of meningitis which is really tuberculous has ever done any good, and it is probable that the success which has been claimed for this treatment is attributable to faulty diagnosis—I mean to say, that it is probable that the meningitis was of syphilitic rather than of tuberculous nature. That an inflammation of the meninges due to syphilitic neoplasms might be benefited by a course of mercurials, there can be little doubt. The good results which have been ascribed to quinine in meningitis are probably explicable on the supposition of errors in diagnosis. There are, in fact, two affections whose symptoms are almost identical with those of meningitis: such are, attacks of pernicious fever of the cerebral form, and typhoid fever in infants. In the first class of cases quinine has a marvelously happy effect. I have even known children, given up to die from tuberculous meningitis, to get well under quinine, for their brain disease was simply the cerebral congestion of malignant remittent fever. These facts ought to be well impressed on your minds, and, whenever you have reason to suspect the toxæmic influence of malaria, you should hasten to give quinine, and, as the stomach is often irritable, you may have to administer the quinine in suppositories, or in the form of hypodermic injections of the bromhydrate.

The same remarks are applicable to typhoid fever, and recently Barthez has called attention to this point, and recommended that whenever, in the case of a young child, you are in doubt as to whether you ought to call the disease meningitis or typhoid fever, you should give large doses of quinine, say a scruple in four doses (which may advantageously be administered in coffee). If marked amelioration follows this medication, you may, with good reason, suspect the disease to be typhoid fever, and not meningitis.

There is a second group of medicaments addressed to the nervous symptoms developed by the meningeal inflammation. To calm the delirium, the agitation, and the convulsions which occur at different periods of the disease, opiates have been given; but chloral and bromide are especially to be recommended. Chloral, in combination with bromide, is here as useful as we found it to be in whooping cough; if it does not cure, it alleviates. In cases where cures are reported from this treatment, it is more than probable that the disease was not meningitis, but the eclampsia of childhood, dependent on peripheral or toxæmic and not on central lesions.

Two medicaments have been prescribed, from empirical considerations, in this affection—the extract of walnut-leaves and iodide of potassium.

Luton, of Reims, was the first to vaunt the curative efficacy of the extract of the leaves of walnut (known as extract of Grandval); this medicament was directed to the tuberculous cachexia, and not to the inflammation. Luton seems to have had some little success, but no one at the present day has any confidence in this treatment.

It is not so with iodide of potassium. Experimented with first by Blache, then by Bourrouse, and landed by Bonamy, iodide of potassium counts many earnest advocates. In fact, I think that, considering the testimonials in its favor, and the perfect safety of this medicine, it is well always to have recourse in hydrocephalus to the iodide, of which as much as two grammes (2 s.) may be given to children daily in divided doses.* It is possible that the cases where this treatment does good are of syphilitic character, and that it is ineffective in real tuberculous meningitis. I am unprepared to decide this difficult question.

You see, gentlemen, that, notwithstanding the promises which I laid down at the beginning of my lecture relative to the curability of tuberculous meningitis, I am obliged to admit that we have no certain curative means, and, unhappily, when we see little patients get well whom we have treated for this malady, we are in doubt whether the recovery is not rather the result of an error in diagnosis than of anything which we have done.

Therefore, these two facts—the possibility of the resorption of the inflammatory and tuberculous products, or the possibility that you have mistaken for a malignant tuberculous affection one that is benign and curable—should encourage your efforts in the treatment of this formidable disease.

Moreover, even in tuberculous hydrocephalus you will often observe marked remissions which are misleading, and ought always to keep you on the watch. After passing through the most severe phases of the disease, after the de-

* The formula of Bourrouse, of Laffont, is as follows: I. Iodide of potassium, five grammes; water, sixty grammes. M. A teaspoonful every three, four, or five hours, well diluted. Never exceed two grammes a day ("Moniteur des sciences méd.," June, 1861).
librium, convulsions, and coma, one sees the child suddenly revive, intelligence come back, the convulsions cease, and the family are ready to exclaim that a miracle has been wrought. Unhappily, this treacherous remission is short; the cerebral symptoms return, and the fatal event soon comes.

Among the various affections which may be confounded with tuberculous meningitis there is none more deserving of mention, because more common—attacking as it does both adults and children—than simple acute meningitis. This disease, within certain limits, is curable; aetiologically, of course, it is distinguished from the other meningeal inflammation by the absence of tubercle granulations. For these simple meningites the treatment is the same as for the tuberculous; you should especially insist on cold applications, revalves, and emollients. But in this form of meningitis our success will depend on the degree of the inflammation and the extent of the lesions. In respect to this latter point, the brain is sometimes strangely tolerant. We now and then see tumors of considerable size develop in the interior of the cerebrum, or even at its periphery, with a latency such that scarcely any symptoms reveal their presence. On the other hand, we frequently observe, from the moment that the cerebral cortex is affected, even if the lesion be quite circumscribed and of little depth, the most pronounced disorders in the sphere of intellect and motility, owing to irritation of the nerve-cells of the peripheral strata. It is for this reason that these meningeal inflammations are accompanied by grave symptoms, even when the phlegmasia is not extensive.

The greater part of mental disorders which are grouped under the general name insanity are only chronic meningitis, and the mental disturbances, so numerous and so similar, which alcohol produces, result from the pachymeningitis which the presence of alcohol determines in the cerebral envelopes. I can not enter into the treatment of these chronic meningites—treatment little understood, and which belongs to the domain of the expert in mental diseases rather than that of the ordinary practitioner.

I must, before concluding, speak of the treatment of infantile convulsions. It is an interesting subject not yet well elucidated, for the convulsions of infancy are only symptoms, which may be produced by a variety of causes. They may depend on inflammation of the brain or its membranes, or on certain conditions of dyscrasia (uremia, for instance), and belong to the group of ecampsias, or else they are simply reflex manifestations, generally of little gravity, which appear in the course of various affections, as dentity and diarrhea.

In eclamptic convulsions, or in those which have for their point of departure reflex action, the best mode of treatment consists in the internal administration of bromide of potassium, or chloral, or in inhalations of chloroform or ether. All medicaments which anesthetize the brain seem to do good in these cases; it is from this consideration that Trousseau proposed compression of the carotids. I warn you to be chary in the use of revalves—such as simpasms and blisters—in these cases, for severe cutaneous gangrenes, more difficult to cure than the convulsions themselves, have more than once been produced by the prolonged action of even a mustard cataplasm, and this in consequence of the insensibility which results from the fit.
these common symptoms first, before we speak of the special symptoms which belong to each subdivision.

In the first place, we have certain changes in the urine. There are very often changes in the quantity of urine passed. It is diminished in amount whenever there is produced in any way a sudden venous congestion of the kidneys. The moment such a venous congestion is established there is regularly a diminution in the amount of urine produced, but this affects the watery more than the solid portions of the urine, and, therefore, you may get it diminished in quantity, but of a normal or of a high specific gravity. If, for instance, a patient is suffering from a febrile movement of any kind, then there will be a vascular congestion of the kidneys, and the urine will be diminished in amount; and this is ordinarily a diminution in the watery rather than in the solid portions, and so the specific gravity of the urine will either be normal or higher than usual. Again, when injuries are done to the urethra, we find a very marked diminution of the urine in some cases. The simple passing of a urethral bougie is sufficient in some patients to lessen the amount of urine to only a few ounces in the twenty-four hours, or even to a complete suppression, and greater injuries than this are still more apt to produce a great diminution or a complete suppression of the urine. In these cases there is not usually any congestion of the kidneys, and the only way we are able to explain the diminution in the urine after such an injury is to suppose that there is a sudden constriction of the arteries in the kidneys, so that a sufficient amount of blood does not pass into the organs, and, therefore, the amount of urine excreted is diminished.

Then, again, we find that changes taking place in the epithelial cells of the kidneys regularly produce a diminution in the amount of urine. But this effect is more marked when these changes in the epithelial cells are produced suddenly than when they take place slowly. If, in the course of an acute disease, there are produced marked changes in the epithelium of the kidneys, there is almost always at the same time a very marked diminution in the urine; but if these changes take place more slowly and gradually, then there may be no diminution in the watery portion of the urine at all, but the solid portions will be diminished in amount. If the ureters become occluded in any way, then the amount of urine is also diminished. If this occlusion is effected very suddenly—as, for instance, by a large calculus in the pelvis of the kidney suddenly passing into the ureter and blocking it up at once, and if then the patient happens to have only one kidney, or if the other kidney is diseased—then there will be produced at once a complete suppression of urine, and the function of the kidneys, so far as the urine is concerned, is abolished. But if the occlusion of the ureter takes place more gradually, as by the passage of a small calculus into it, not large enough to obstruct it completely, or by the pressure of a new growth upon the ureter so as to constantly occlude it more and more, then there is regularly a diminution not only in the amount of water, but also of the solid constituents of the urine.

Generally speaking, whenever the urine is suppressed or very much diminished it produces cerebral symptoms which are more or less marked. By these I mean such symptoms as headache, restlessness, sleeplessness, delirium, convulsions, unconsciousness, coma, and the like, and any of these are apt to be developed whenever the amount of urine is seriously diminished. In some cases, however, this production of cerebral symptoms does not take place. When, for example, the urine is diminished as a result of injury to the urethra from the passage of bougies, or from the performance of internal urethrotomy, or the forcible dilatation of a stricture of the urethra, we do not usually have cerebral symptoms induced. But the patient is more apt to be seized with repeated rigors and vomiting, and he may pass quickly into a very alarming condition of collapse with feeble heart action, and this may be followed by great prostration terminating in death, or the patient may gradually emerge from this condition after it has existed for some time. Thus, then, the urine is not merely diminished in quantity, but entirely suppressed by the occlusion of the ureters, or by the extirpation of a single kidney when the other is wanting, or when one good kidney is removed by mistake instead of the diseased one. In these cases the function of the kidneys is abolished and the patient passes no urine at all, yet he does not develop cerebral symptoms usually for a number of days. But toward the close of the patient’s life, for these cases are always fatal after a certain length of time, there will be produced some cerebral symptoms. So that, although the mere diminution in the amount of urine is usually accompanied by the production of cerebral symptoms, yet absolute suppression is not necessarily so. It is very important to remember this distinction as to the class of cases in which cerebral symptoms may be absent, and especially those cases of which I have just spoken—namely: injuries to the urethra, occlusion of the ureters, and extirpation of the only good kidney. In these cases the cerebral symptoms are either not developed at all, or else not till the lapse of a number of days; so the mere abolition of the function of the kidneys is not by itself sufficient to produce cerebral symptoms.

In other cases we find that the urine, instead of being diminished in amount, is really increased. The most marked example of this we get in the case of diabetes, and especially in cases of saccharine diabetes, and in so-called incipient diabetes where there is no sugar present in the urine. In these patients we have a very large amount of urine passed in the course of a few hours. In some cases of disease of the kidneys, especially if there is a marked change in the stroma of the kidney and in the Malpighian bodies, and a waxy infiltration of the kidney and the Malpighian tufts, we often get a very decided increase in the amount of urine; but this is an increase as regards the watery portion of the urine only, and not of its solid constituents. These people do not get rid of as much of the solids as they should, and so the urine is of a low specific gravity. But in saccharine diabetes it has a high specific gravity, from the abundance of sugar in the urine.

When you are trying to find out the causation of the changes in the amount of urine, you have to look, in the first place, to the condition of the circulation—that is, you must find out how great the tension of the blood is in the
arteries. The greater the amount of arterial tension, so much the greater will be the amount of urine produced, and, the less the arterial tension, the less will be the amount of urine as a rule. Thus the exact condition of the renal arteries and capillaries should have an effect in regulating the amount of urine. If these suddenly become contracted from any cause, then the amount of urine should be diminished; but if, on the other hand, they become suddenly dilated, then the urine should be increased in quantity, and if these vessels are diseased, then the quantity of urine should vary with the character of the disease, and whether or not it is such as to prevent the proper amount of arterial blood from getting to the kidneys. The condition of the renal epithelium also has an influence, and especially in regulating the amount of solid constituents in the urine; and, lastly, the condition of the blood itself, and whether or not it has its natural composition, affects the quantity of urine.

The specific gravity is an indication of how large a proportion of solid constituents there is present in the urine. If the amount of water is diminished and the quantity of solid matter is constant, then the specific gravity of the urine will be increased, and, if it contains a foreign body, such as sugar, for instance, then the specific gravity will be increased also. But if the amount of water is increased while the amount of solids remains the same, then the specific gravity will be low; and if the production of solid constituents is diminished, then the specific gravity will also be low, no matter how small the amount of urine produced. So in some cases of chronic Bright's disease, the patient may pass only a few ounces of urine of a low specific gravity in the twenty-four hours.

In some cases of kidney disease we find blood in the urine. When we do find blood in the urine, it comes most frequently either from the bladder or the blood-vessels of the pelvis of the kidney, or from the kidney tissue itself. That which comes directly from the bladder we are not now concerned with. The blood from the pelvis of the kidney is usually due to a condition of chronic pyelitis, which may be produced in different ways, or to the presence of calculi in the kidney, or of new growths in the pelvis of the kidney. The blood from the tissue of the kidney itself may be found either in connection with an acute congestion of the kidneys or with a chronic congestion of the kidneys, though in this latter case you will very seldom get blood in the urine, and, when found, it is an exception to the rule. But with acute congestion you may get a very considerable amount of blood in the urine. The chronic forms of Bright's disease are not often accompanied by the presence of blood in the urine, unless the disease takes on an acute condition, but in that case it is found. While, however, it is going on in its ordinary chronic course, you will hardly ever get any blood. But when there occurs an acute exacerbation of a chronic Bright's disease, then you may have blood in the urine. The acute cases of Bright's disease do very often give blood in the urine, and sometimes, too, in considerable quantities. So in cases of Bright's disease the presence of blood in the urine is either an indication of an acute inflammation of the kidneys, or of an acute exacerbation of a chronic inflammation.

In most cases of Bright's disease we find, at some time in the course of the disease, albumin in the urine, and the particular kind of albumin that is characteristic and of any significance in this disease is the so-called serous albumin. Albumin of any other form is of no consequence in Bright's disease, but serous albumin belongs especially to Bright's disease. But we find that serous albumin, besides being present in the urine of patients with Bright's disease, may also be present in other people at times. Thus, there are persons in whom the presence of albumin seems to be a physiological rather than a pathological condition, and this is a very common experience. So it is important to remember that there are a certain number of people with a small amount of albumin in their urine who are otherwise healthy; and there are some persons who, for a number of years in succession, have always in the urine a little albumin in such an appreciable quantity as to be readily detected by the ordinary tests, though never in very large amounts. I mean that in these cases the albumin is present at some time during nearly every day, though it is not always to be found during the whole of the twenty-four hours. Some will have no albumin in the first urine passed on rising in the morning—that is, before they have eaten their breakfast—but the next specimen, taken from the urine passed a few hours after breakfast, will contain an appreciable amount of albumin, and it is especially marked in the later hours of the morning. These patients also, quite frequently, have in the urine a small amount of sugar; but this will not be constant during the whole twenty-four hours, but it will be present during some part of the day, and will be found on some days and not on others. The patient may go on in this way for a number of years and all the time have a little albumin and a little sugar in the urine, and yet he will perceive absolutely no change in his general health, and sometimes these are particularly strong and robust people. Then, again, after a number of years, the albumin and sugar may entirely disappear never to return, and you can follow some of these persons up for years after, and they never develop any other signs of disease of the kidney. There are other persons in whom you will find that albumin is always present in the urine after taking severe exercise, and this is a very common condition. In these cases, for the next few hours after exercising, there will always be some amount of albumin in the urine, and the rest of the time there will be none. Then we find, still further, that there are some young persons, between fourteen and twenty years of age, who, sometimes for weeks or months in succession, will have a considerable amount of albumin in the urine; and while it continues present there may be some change in their general health, such as a little anaemia or a little loss of appetite, and a loss of flesh and strength; then, after a time, the albumin suddenly disappears and the patients return to their natural condition of health, and never in the future manifest any further symptoms of kidney disease.

Then we find also that, when patients have had general convulsions from any cause, they will often have after
them a certain amount of albumin in the urine. We also find that some injuries of the brain, such as may result from falls, or from severe blows on the head, or from anything causing concussion of the brain, will be followed sometimes by the appearance of albumin in the urine. Still further, we find that the operation for the transfusion of blood is sometimes followed by the presence of albumin in the urine for a short time. In all these cases, then, that I have mentioned we may have the presence of appreciable amounts of albumin in the urine without any further symptoms of disease of the kidneys.

When we come to consider the kind of cases in which we get albumin in Bright’s disease, we find that it is most common and most abundant in acute parenchymatous nephritis, in chronic parenchymatous nephritis, in acute diffuse nephritis, and in those forms of chronic diffuse nephritis in which the kidney is increased in size, and the most marked pathological change is in the epithelium of the tubules; but the albumin in the urine is least constant and abundant where there is a waxy infiltration of the Malpighian bodies, and in those cases of chronic Bright’s disease in which the changes are most marked in the stroma of the kidney and in which the kidneys are diminished in size.

It is very difficult to understand the exact method by which the albumin finds its way from the blood to the urine. It seems to be derived directly from the plasma of the blood. But it is difficult to find out why no albumin is found in the urine in health as a rule, and yet in some healthy individuals the albumin comes and goes at intervals, although there are no structural changes in the kidneys. It is supposed by some that the cause of the albumin in the urine in diseases of the kidneys is on account of changes that have taken place in the cells lining the capillaries of the Malpighian bodies. It is believed by some that when the capsules of the Malpighian bodies and the tuft of vessels within the Malpighian capsules are covered, as they should be, by a layer of epithelial cells, then there is no transudation of albumin from the blood into the tubules of the kidneys; but as soon as these cells become obliterated, then changes in the urine take place. Others believe that the presence or absence of albumin depends upon the degree of the pressure of the blood in the renal arteries. Some hold that increased blood pressure, and others that decreased blood pressure, causes it to appear. Others attribute it to changes in the walls of the arteries, and others to congestion of the renal veins, or to changes in the composition of the blood, while others still look to the condition of the kidney tubules to find the cause of the production of albumin.

But, as a matter of fact, we find that albumin is present most constantly, and in largest amounts, in cases where there are decided changes in the epithelium of the convoluted tubes, and especially where these changes are produced rapidly there will almost always be a large amount of albumin present in the urine; but if these changes take place slowly, then sometimes there will be a good deal of albumin and sometimes only a little.

Another change that occurs regularly in the urine be-

TWO CASES OF POISONING WITH ILLUMINATING GAS SUCCESSFULLY TREATED BY THE INHALATION OF OXYGEN.

By ALONZO CLARK, M.D., LL.D.,
EMERITUS PROFESSOR OF PATHOLOGY AND PRACTICAL MEDICINE IN THE COLLEGE OF PHYSICIANS AND SURGEONS.

So far as I know, these two cases of poisoning with illuminating gas are the only cases of the sort on record in which the treatment by the inhalation of oxygen has been resorted to. The histories of the cases, somewhat condensed from the written reports of the house physicians, are as follows:

CASE I.—A woman, forty years old, was brought to Bellevue Hospital, and admitted into my service, May 30, 1882. She and her daughter had gone to bed the night before, and about noon they were found in a state of unconsciousness, the room where they had been lying for fifteen hours being filled with illuminating gas, the odor of which they had noticed on going to bed. On recovering from her insensibility, the patient could remember nothing that had happened from the time of her going to bed until she regained consciousness in the hospital ward, after the lapse of twenty-four hours.

At the time of her admission, she was found to be suffering from pulmonary edema; the radial pulse was scarcely perceptible, she was unconscious and cyanotic; her extremities were cold, there was trismus with rigidity of the flexor muscles, the urine was passed involuntarily, the pupils were slightly contracted, and a frothy mucus issued from the mouth. Her temperature was 90° F., and her respiration 40.

I entered the hospital shortly after she was brought in, and directed the inhalation of oxygen. Its administration was kept up for three hours. In addition, dry cups were applied over the chest, and tincture of digitalis was given endemically—in all, to the amount of thirty minims. Whisky also was given subcutaneously, and hot-water bottles were applied to the extremities. Occasionally, too, the patient was aroused by flagellation.

This treatment extended over a period of four hours, at the end of which time the woman began to show signs of returning consciousness; the pulse became more perceptible and regular, warmth returned to the extremities, and the temperature and the respiration were found to be normal. The next day the patient was able to tell her own story, and was soon afterward discharged.

CASE II.—The daughter of the first patient, a girl twelve years old, was admitted at the same time, in Dr. Loomis’s service. Her breath had a very strong odor of gas; she was completely comatose, the breathing being stertorous, the eyes closed, the conjunctiva insensitive, and the pupils contracted and insensitive to light; the pulse was 156, extremely feeble, and occasionally intermitting; the respirations were 30 and shallow. There were clonic spasms involving the left side of the body, with bird-claw contraction of the fingers of both hands. The urine and feces were passed involuntarily. The face and clothing showed evidence that the patient had vomited a good deal before reaching the hospital, but after her admission there was no vomiting.

Seeing that my patient was being treated by the inhalation of oxygen, the house physician, Dr. Pryor, resorted to the same treatment in this case, and, in addition, gave a hypodermic injection of a sixth of a grain of sulphate of atropine. This patient also recovered.

TWO CASES OF OPHTHALMOPLEGIA EXTERNA, ASSOCIATED WITH DISEASE OF THE OPTIC NERVES FROM BRAIN TUMOR.

WITH AUTOPSY.

By CHARLES STEIDMAN BULL, M.D.,
NEW YORK.

The two cases of ophthalmoplegia externa associated with disease of the optic nerves, which are here reported somewhat in detail, were due to brain-tumor; and they are of interest, partly because of the opportunity they gave for studying the several symptoms in the order of their development, and partly because of the autopsy which was obtained in each case.

In central paralysis of associated ocular movements it is not always easy to distinguish between cases where the lesion is at the basal centers of motion and cases in which the lesion is situated in the cortex. In those cases of paralysis of several ocular muscles in which the power of motility of the several muscles is gradually lost, or in which both eyes have become almost fixed and immovable, the lesion is probably always basal. The symptoms here are usually more advanced in one eye than in the other, and sometimes, as in the first case here reported, the motor paralysis is associated with a progressive double optic neuritis, because of the close relation which exists between the nuclei of origin of the motor and optic nerves at the base of the brain. In the first case reported, there was no piosis of either upper lid, and this fact may be of interest in connection with Ferrier’s idea of the possible existence of a separate center for the elevation of the upper lid toward the upper part of the anterior lobe of the cerebrum. Most observers have noticed that in well-marked cases of ophthalmoplegia externa the levator of the upper lid is much less affected than the other muscles, and the paralysis of this muscle usually recovers first. Nestle’s hypothesis that in central paralysis this might be accounted for by the movements of the upper lid being more automatic than those of the eyeball, but admits that this explanation would hardly apply in cases of disease of the nerve-trunk (see the “British Medical Journal,” December 2, 1882). In both the cases here reported the iris and ciliary muscle were affected, the latter slightly, as well as the extrinsic muscles, while the levator of the upper lid was involved only in the second case. In the first case, the lids were retracted somewhat as in Basedow’s disease. In these cases of central origin, when the optic nerve is affected, the lesion is usually a papillitis or neuro-retinitis, rather than a progressive atrophy. But,

* Read before the American Ophthalmological Society, July 19, 1883.
BULL: OPHTHALMOPLEgia EXTerna.

in the second case, the lesion would probably have been a simple descending atrophy, if the patient had lived long enough, rather than a neuro-retinitis.

Case I.—J. L., aged thirty-four, was first seen by me on February 1st, 1831. The patient was a civil engineer by profession, and had never suffered from any serious disease, except a severe and obstinate attack of malarial fever some years before. For about fourteen months he had suffered from occasional attacks of severe headache, which at times was limited to the vertex, and at other times was confined to the occipital region. These headaches gradually increased in frequency and duration, and for the past two months were nearly constant. For the past three months he had suffered from diplopia, which at first did not trouble him very much, but after a time it changed in character and became very confusing. When either eye was closed, he at first could see perfectly well with the other, but about three weeks before he presented himself for treatment, he noticed that the vision of the left eye was quite defective. Since the headaches began they had occasionally been accompanied by nausea, but of late the nausea came on with every on-set of pain in the head, and often there was actual vomiting. He also complained of vertigo, which was always brought on by any sudden movement, and occasionally appeared at other times. With the exception of the headaches and diplopia and the gastric disturbance, the patient's health was good, and his appetite remained excellent till near the last. The urine had been repeatedly examined and nothing abnormal found. When I first saw him, the most marked objective appearance was the staring appearance of the eyes. There was a moderate amount of exophthalmos in a direction forward, with almost complete immobility of the left eye and limitation of motility inward of the right eye. Both pupils were equally dilated and very sluggish. The upper lids appeared retracted and drawn upward. In the right eye, \( V = \frac{1}{2} L \), and he could read Sn. D = 0/8 from 8' to 10'; in the left eye, \( V = \frac{1}{2} L \) eccentrically, and unimproved by any glass. There was a large, irregular, central scotoma in the field of the left eye, and a slight indistinctness of central vision in the right eye, though no scotomas could be mapped out. The color-scotomas in the left eye co-extensive with the visual scotoma, except on the nasal side of the field, where it extended somewhat further. The media were clear in both eyes. In the left eye there was an extremely well-marked papillitis which extended some distance beyond the margin of the disc, and there was an extensive, yellowish-white exudation in the region of the macula, with numerous punctate and striated hemorrhages. In the right eye there were the signs of a papillitis in the first stage, but no hemorrhages and no visible exudation near the macula, or between the latter and the disc. The urino was carefully examined, but neither albumin nor casts were found. Its specific gravity was 1:023, its reaction faintly acid, and there was a small amount of sugar. An examination of the muscles of the eye showed on the left side a complete paralysis of the internal and superior recti muscles, partial paralysis of the inferior recti, and an apparent defect in the action of the superior oblique muscle. On the right side there was complete paralysis of the internal rectus only, all the other muscles being intact. Two days later, on February 16, 1831, vision had sunk in the left eye to \( \frac{1}{2} L \), and in the right eye to \( 1 \), and the neuro-retinitis had become nearly as marked as in the other eye. On February 19th and 20th he vomited all the food taken, and complained of severe frontal headache, and the heart's action was accelerated. Toward evening of the latter day the vomiting ceased, but he lost all power of recalling what had occurred during the day. At half-past nine in the evening of the 20th he rose and went to the water-closet and had a natural evacuation from the bowels, and on his way back to bed he drank a glass of water. At half-past ten, one hour later, he suddenly became comatose, with very slow and shallow respiration and very rapid action of the heart. Death ensued in about five minutes after the attack began. At no time was there any increase of temperature, nor any interference with either general motion or sensation.

Autopsy thirty-six hours later.—The ordinary signs of cadaveric rigidity were well-marked. The vessels of the scalp were found exceptionally bloodless. On the removal of the calvarium there were no signs of any special hyperpnea or inflammation either of the endo- or meninges. The facial, respiratory, and other bodies were well-marked. On opening the cranial cavity there was seen to be a large amount of cerebro-spinal fluid. Both lateral ventricles were enormously distended, particularly the one on the right side, which contained nearly four ounces of fluid. The fourth ventricle was distended and its floor softened throughout nearly the whole extent. In the right third ventricle was a cystoid mass as large as a walnut, which was attached to and developed in the anterior end of the choroid plexus. The optic chiasma was compressed, and both optic tracts were flattened to ribbon-like bands across the crura cerebri. There was a spot of softening, about as large as a silver quarter-dollar, at the anterior end of the inferior convolution of the right middle lobe. Careful dissection was made of the chiasma and optic nerves as far forward as the eyeballs, the roofs of the orbits and portions of the ala of the sphenoid bone being removed for the purpose with the bone-forceps. No distension of the sheath was found until close to the entrance of the nerve into the sela, where there was a slight distension. This was more marked in the left eye than in the right, where it did not extend all round the circumference of the nerve. The posterior portions of the eyes, with the optic nerves, chiasma, and tracts as far as the cerebral peduncles, were removed for microscopic examination. The thoracic organs were found tolerably healthy, with the exception of some bands of adhesions between the costal and pulmonary pleura on the right side—the remains of an old pleurisy. The liver was slightly enlarged and fatty, and the spleen was enlarged and showed sign of old infarctions. The kidneys were normal in size, and the cortex showed slight signs of disease. The other organs were not examined. 

Case II.—J. T., aged thirty-three, was first seen by me early in October, 1882. This patient had had a nose upon the penis thirteen years before, which was probably a chancre, as it was followed by a general cutaneous eruption, ulcers in the throat, which have left their traces in the fauces, and rheumatic pains in the limbs, and by one attack of inflammation in the right eye. For the past four years, the patient stated, there had not appeared any symptoms which he could attribute to syphilis. He had never had any malarial disease, and for more than three years had not missed a day at his work, which was that of a builder. He used tobacco to excess, but had never used any alcoholic stimulants. About four months before he applied for treatment he began to suffer from headaches, which were always frontal or through the temples, and never lasted more than a few hours, but they gradually increased in frequency, severity, and duration, until for more than a month they had been constant, and were at times so severe as to almost craze him. During this last period he began to see double, the diplopia being at first confined to the left side of the binocular field of vision, but soon invaded the entire field. His gait became very uncertain, especially when he rose from a chair or turned suddenly, the feet being thrown either to one side or the other. That this was not due to the diplopia alone was proved by bandaging one eye and then causing the patient to rise suddenly, walk rapidly, or turn round suddenly;
the staggering and sensation of falling occurred as before, though
the patient thought that it was not so marked. He had a
blanched, unhealthy look, which, however, was different from
the waxy look of chronic renal disease. He had a double sys-
tolic cardiac murmur and an intermittent pulse. The urine, on
examination, showed albumin, but no sugar and no casts. In
the right eye, V = \( \frac{5}{5} \); in the left eye, V = \( \frac{2}{3} \), and he could
read Sn. D = 1\( \frac{2}{3} \) at 12\( " \), but the accommodation was slightly
limited. The field of vision was slightly limited on the nasal
side in the right eye, but there was no scotoma in the field of
either eye, and no apparent interference with the color-sense.
There was complete paralysis of both third and sixth nerves;
the eyeballs stood slightly divergent and immovable; there were
troons of both upper lids, slight exophthalmus, and moderately
dilated and immovable pupils. The media were clear, and there
was nothing pathological in the fundus of either eye, except a
slight indistinctness and edematous condition of the temporal
margin of the optic disc and adjoining portions of the retina in
the right eye. On the supposition that the cause was syphilitic,
and that it might also be located in the kidneys, the iodide of
potassium was administered in increasing doses, beginning with
fifteen-grain doses three times a day, and he was also given cold-
liver oil, quinine, and iron. On account of the condition of the
kidneys, the administration of the potassium iodide was fre-
cently interrupted, and an interval allowed to elapse before
recommencing its administration. Under this treatment the
patient's general condition improved, the albumin nearly disap-
peared from the urine, and the staggering gait became less
marked. There was, however, no improvement in the diplopia
and no lessening in the severity of the headaches, which had to
be relieved by analgesics. On October 23d the patient had a
series of epileptiform convulsions, which occurred so frequently
that chloroform had to be administered. From this time the
patient slowly grew worse, though there was no recurrence of
the convulsions. The headaches continued with the same se-
verity, and the staggering gait and vertigo returned so that the
patient kept his bed. On the evening of November 5th he had a
convulsion, from which he passed into a comatose condition,
which gradually deepened until the following morning, when
death occurred. Ophthalmoscopic examinations were made
daily up to the day of his death, but no further changes were
noticed in the fundus of either eye, though vision had steadily
failed during the last three weeks of life; the last record made
was on October 28th, when it was found reduced to \( \frac{2}{5} \) in the
right eye and \( \frac{4}{5} \) in the left eye.

Autopsy thirty hours after death.—Cadaveric rigidity well
marked. Nothing abnormal was noticed in the scalp or calva-
rum on removal. The dura mater was firmly adherent, at two
or three points, to the calvaria, and the blood-vessels were
somewhat engorged. Considerable fluid was found in both lat-
eral ventricles, and a little in the fourth ventricle. There was
some softening of the cerebral substance discovered on incising
the right middle cerebral lobe, and about midway in the sub-
stance of this lobe, and extending forward into the posterior
part of the right anterior lobe, near the median line, was a
dense tumor, apparently sarcomatous in nature, about the size
of a small pigeon's egg, which, as it lay in the brain substance,
was somewhat nearer the base than the convexity, and was sur-
rounded by a layer of softened brain tissue of varying thick-
ness. The right lateral ventricle and the portion of the right
middle cerebral lobe on the median side of the tumor were
pushed over beyond the median line to the left side, and the
topographical anatomy of this region was considerably distorted.
The optic tracts were slightly flattened, and the third and sixth
nerves of the right side were pressed upon and flattened by the
pressure of the tumor in the lobe, and this undoubtedly af-
fected indirectly the corresponding nerves on the left side.
There was no distension of the sheath of the optic nerves, and
no flattening of the chiasm. Both optic tracts were the seat of
moderate interstitial neuritis, but this microscopic change was
but very slightly marked in the optic nerves, and could be
traced but a short distance in front of the chiasm. The heart
was somewhat hypertrophied, and was the seat of pronounced
valvular disease. The liver was large and fatty. The spleen
was apparently normal. The kidneys were somewhat con-
tracted, and the cortex was decidedly diseased. The other
organs were not examined.

THE AGONY OF DEATH BY CRUCIFIXION.

By HENRY C. COOPER, M.D.,
NEW YORK.

"Man's inhumanity to man" has been pre-eminent in
all ages. In ancient times it mattered little whether it was
the law to be satisfied or personal vengeance to be gratified;
the punishment which would cause the utmost physical
pain seems to have been in the greatest demand. But, with
the advent of Christianity, the modes of inflicting capital
punishment have become modified, and infinitely more mer-
ciful. Nero and his caldron of boiling oil have passed
away. The cry of "Christinos ad locones!" is no longer
heard. The Caesars and Dominats, with their horrid cruel-
ties; the Venetian Council of Three, and the Bridge of
Sighs; the Spanish auto da fe, and its ghastly processes;
the fiery stakes at Smithfield and Oxford—have in their
turn disappeared, the garrote, the guillotine, the knout,
the axe, and the rope taking their place. By gradations the
majesty of the law has been vindicated in all lands, with-
out the terrors of ancient barbarisms, until, in this nine-
teenth century of grace, all civilized communities demand
that a life to be sacrificed shall be sacrificed swiftly, and
without needless pain. True, various nations have different
opinions as to how this may best be accomplished; but the
American and English governments have decided that hang-
ing is the most merciful. As compared with the Spanish
instrument of death, the garrote, it is questionable whether
or no hanging is the most merciful. A bungling executioner
may, in either case, cause unnecessary tortures. With
these subjects, however, this paper has nothing to do.
The writer desires simply to set forth the various modes of
crucifixion as adopted by the ancients, and to show what
terrible sufferings the wretched malefactor had to undergo
before death came to his relief. Hours and days of un-
mitigated torture; a thirst which was unquenchable; a pro-
longed suffocation; a horrible gasping for breath, inten-
sified only by a moment's respite; the bites of the vultures
of the air, and the stings and burrowings of insects; the
burning by the rays of the noonday sun, and the cold,
clammy dews at midnight—tell us, in awful language, of that
dice ire, from a repetition of which the present day is hap-
ply delivered. In comparison, our present capital punish-
ments are most merciful, and the vindication of justice
most humane.

ORIGIN OF THE DEATH BY CRUCIFIXION.—In the Orient,
that was considered an art whereby the greatest and most
prolonged tortures could be inflicted on the culprit. It was in the East where the victim was smeared with a sweetened syrup and tied to a tree, there to be left a prey to the myriad of ants which were speedily attracted.

The term "crucifixion" was a general one. All modes of execution were termed crucifixions by the ancients. Thus, when the Persian Haman was hanged, the custom was borrowed from the Babylonians, and termed a crucifixion. But the earliest example of crucifixion on record is that of Pharaoh's chief baker, said, in the earliest English version of the Bible, to have been hanged (Genesis, xi. 10-22); but by Josephus to have been crucified (Whiston's "Josephus," vol. i. pp. 65, 66).

Herodotus states that Darius "crucified" three thousand Babylonians, though it is by no means probable that very many of them were actually placed upon a cross.

So, also, when the robber Sinias bent two pine-trees to the ground, and to the interlacing portions bound his victim, the trees were then unbound, and, springing back, the victim was dismembered; this also was termed a crucifixion, as was also the punishment inflicted upon Prometheus, on Caucasus, and Andromeda.

The Greeks skilfully resorted to crucifixion; the Carthaginians never. But the Romans were most artistic in carrying out this form of punishment. Pliny writes that Tarquinius Priscus invented it, and that it came into general use between 260 years and 160 years B.C. The culprit was entirely at the mercy of the executioner; the judge, having pronounced judgment, was never present when the sentence was carried into effect.

In Rome, all culprits who were slaves were crucified, as were also traitors and insurgents. The specific charge which made Pilate order Jesus Christ to be crucified was the accusation of insurrection made against him, and Pilate hoped that, by killing the Jewish Messiah in the most ignominious manner, he would thereby obliterate the most dangerous Jewish doctrine.

**Modes of Crucifixion.**—The most primitive seems to have been an upright tree, to which the victim was either bound or nailed.

In Ezra vi, 11, it is ordered that "whosoever shall alter this word, let timber be pulled down from his house, and, being set up, let him be hanged thereon, and let his house be made a dung-hill for this."

Titus had no time to add a horizontal beam, when crucifying five hundred Jews a day for months. He simply drove a pole into the ground, to which the victim was lashed, and he was left to die.

Slaves were generally punished by having a "furca" (fork) slipped over their necks, to which their arms were tied, and this was hoisted to the top of a pole, and secured there by a rope fitting into a groove. This device evidently suggested the more recent cross, to save time, and as being more artistic.

It was usual to nail the hands, but to bind the feet. It is erroneous to suppose that a single spike secured both feet to the cross, one foot in front of the other. A spike was driven through each foot, sometimes to a support fixed on the cross just beneath the plantar surface of the feet. Additional cruelty was sometimes practiced by the victim being seated on a spike or "horn" (Justin Martyr), though at times a piece of wood was so placed that he might rest on it.

**Phenomena attending Crucifixion.**—The nails, aided by intense heat, soon produced gangrene. Although the culprit writhed in agony for some time, it is doubtful whether any long-continued activity of the body could be maintained. The weight of the intestines, gravitating downward, produced intussusception. The circulation was impeded, the viscera pressing on the veins. The lungs could not be emptied. Insects got into the eyes, nose, ears, and wounds. At nightfall the bones of the legs of those still living were broken, ostensibly to hasten death; but, in reality, to gratify the spectators who were becoming satiated.

Death generally resulted from gangrene of wounds, displacement of viscera, regurgitation of blood through the valves of the heart, pericarditis, and paralysis of heart and lungs. "In many cases death was accelerated by hunger and thirst, the vicissitudes of heat and cold, or the attacks of ravenous birds and beasts, and in others designedly accelerated by burning, stoning, suffocation, breaking the bones, or piercing the vital organs" (Adam Clarke, "Commentary on Matthew," chap. xxvii. v. 33).

According to Origen, Timotheus and Maura, a married pair who suffered about the year 286, under Diocletian, remained for nine days and nights on the cross, exhorting each other, and expired on the tenth day. By order of the Emperor Maximian, in the year 297, seven Christians at Samosata were subjected to long and varied tortures; three of them were taken down from the cross while yet alive, and the Emperor, hearing of this, ordered huge nails to be driven into their heads.

**Accessories to the Death of Christ by Crucifixion.**—The one great object in history, toward which the eyes of civilized generations have been constantly directed, is that of the body of Jesus Christ hanging on the accursed tree. As being typical of the sufferings of many, it is here introduced as bearing upon the subject, and an analysis of His sufferings may not be considered out of place.

It is to be assumed that, the cross lying upon the ground, Christ was laid thereon, and nails driven through the hands and feet. The cross was then raised, and the lower end of the perpendicular portion sunk in a hole that had been dug for it, and made secure and upright. The nail, driven through the palmar surface of the hand, would probably perforate or impinge upon the following (it being assumed that, as "no bone was broken," the nail, on being struck, would glide to its ultimate destination in the cross through the parts offering the least resistance):

1. Integument.
2. Palmar fascia.
3. Superficial palmar arch.
4. Digital branch of median nerve.
5. Tendon of flexor profundus digitorum.
6. Adductor pollicis.
7. Deep palmar arch.
8. Second and third lumbricales muscles.
10. Intersosseous ligament.
11. Bone (doubtless the nail making its exit between the second and third metacarpal bones).
12. Intersosseous ligament.
15. Extensor minimi digitii. \{Tendons.\}
17. Branches of posterior, ulnar, and radial arteries.
18. Digital branches of ulnar and radial nerves.
19. Dorsal fascia.
20. Integument.

In like manner, the nail, being driven through the dorsal surface of the foot, would necessarily perforate or impinge upon the following:

1. Integument.
2. Dorsal fascia.
3. Metatarsal or second and third intersosseous arteries.
4. Branches of the anterior tibial nerve.
5. Extensor brevis digitorum.
6. Dorsal intersosseous muscles.
7. Metatarsal ligament.
8. Bone (doubtless the nail going between the second and third metatarsal bones).
10. Intersosseous plantares.
11. Lumbricales muscles.
12. Branches of internal plantar nerves.
13. Second and third branches of external and internal plantar arteries.
15. Integument.

The Immediate Cause of the Death of Christ.—Quoting Sir J. Y. Simpson, of Edinburgh, Scotland, he says:

Speaking medially, that the cause of death was laceration or rupture of the heart is a doctrine in regard to which there can be no absolute certainty; but, assuredly, in favor of it there is a very high amount of circumstantial probability.

1. His death was not the mere result of crucifixion, for
2. The period was too short; a person in the prime of life, as Christ was, not dying from this mode of mortal punishment in six hours, as He did, but usually surviving till the second or third day, or even longer.
3. The crucified, as is well known, under a lingering process of gradual exhaustion, weakness, and faintness. On the contrary, Christ cried with a loud voice, and spoke once and again, all apparently within a few minutes of His dissolution.
4. No known injury, lesion, or disease of the brain, lungs, or other vital organs could, I believe, account for such a sudden termination of His sufferings by death except
5. Arrestment of the action of the heart by fatal faintings or syncope.
6. Rupture of the walls of the heart, or larger blood-vessels issuing from it.

III. The attendant symptoms—particularly the loud cry and subsequent exclamations—show that death was not the effect of fatal faintings, or mere fatal arrestment of the action of the heart by syncope.

IV. On the other hand, these symptoms were such as have been seen in cases of rupture of the walls of the heart. Dr. Walsh says, when treating of the symptoms indicating death by rupture of the heart: "The hand is suddenly carried to the front of the chest, a piercing shriek uttered, etc." The rapidity of the resulting death is regulated by the size and shape of the ruptured opening. But, usually, death speedily ensues, in consequence of the blood escaping from the interior of the heart into the cavity of the large heart-sac or pericardium, which sac has, in cases of rupture of the heart, been found, on dissection, to contain sometimes two, three, four, or more pounds of blood accumulated within it, and separated into red clots, and limpid serum, or "blood and water," as is seen when collected out of the body in a cup or basin in the operation of common blood-letting.

V. To obtain positive proof that rupture of the heart was the cause of death, a post-mortem examination of the chest would be necessary. In ancient times such dissections were not practised. But the details left regarding Christ's death are most strikingly peculiar in this respect: that they offer us the result of a very rude dissection, as it were, by the gash made in His side after death by the thrust of the Roman soldier's spear.

The size may be inferred from the Apostle Thomas being asked to thrust, not his "finger," but his "hand," into it. (Vide John, xx, 27.) The effect of that wounding or piercing of the side was an escape of "blood and water," visible to the Apostle John, standing some distance off; and I do not believe that anything could possibly account for this appearance, except a collection of blood effused into the distended sac of the pericardium in consequence of rupture of the heart, and afterward separated, as is usual with extravasated blood, into two parts, viz.:

1. Crassamentum, or red clot.
2. Watery serum.

The subsequent puncture from below of the distended pericardial sac would most certainly, under such circumstances, lead to the immediate ejection and escape of its sanguineous contents in the form of red blood, and a stream of watery serum, exactly corresponding to that description given in the sacred narrative, "and forth with came there out blood and water."

VI. Death by mere crucifixion was not a form of death in which there was much, if any, shedding of blood. Punctured wounds do not generally bleed, and the nails, besides being driven through parts that were not provided with large blood-vessels, necessarily remain, plugging up the openings made by their passage. This "shedding of blood," therefore, was actually done in the feel-best possible sense, under the view that the immediate cause of death was rupture of the heart, and the consequent escape of His life-blood from the central cistern of the circulation.

It is evident that Jesus was dead before the lance was used, by the word "stabat," used by St. John, which may either mean perforation or simply "sweeping."

George Gottlob Richter, of Göttingen, was the first to consider the pathology of a crucified body. He considered that an abnoraml return of blood to the body and an undue pressure upon the thorax were the immediate cause of death.

The Roman law required that an intoxicating drink should be given to the victim, but Jesus did not take this, but a Roman drink called "poesea," of which the principal ingredient was vinegar.

Bartholinus states that a robber was crucified by his hands being nailed and his body free. And though the victim, if very fat, was bound by thongs, it is certain that
the "sedile" (foot-stool) was seldom used, and that the feet, if nailed at all, were nailed from the sides. If such a supposition is correct, it may readily be seen how the agony of crucifixion was intensified.

It has been deemed expedient, since the creation of the world, that the evil-doer should be punished. That the punishment was always commensurate with the offense need not here be discussed. Suffice it that we know that in thousands of cases the punishment for crime was brutal, ignominious, and unjust. Death by crucifixion was undoubtedly the most cruel punishment ever devised and carried into effect. Dismemberment, excision, the tearing to pieces with wild horses, the rack, and the screw, were terrible to contemplate, but death mercifully relieved the victim in a few hours. But in our day the garrote and the rope do their work swiftly, and generally the victim is dead within a few minutes.

But the agony of death by crucifixion—who shall describe it? The festering wounds, the dragging weight of the body on the nailed hands, the awful and unendurable thirst, the attacks of birds of prey and the stings and bites of noxious insects, the fierce heat of the sun upon the naked body, the chilling moisture at midnight, the head racked with pain and the body writhing in convulsions, and the long desire for death, which seemingly never comes—afford considerations for the reflective mind of the vast transitions that have been made by men spanning the time between these barbarisms and the merciful codes of the nineteenth century.

And perhaps that day may dawn upon the earth when nations shall leave the punishment of death to Him who said: "Vengeance is mine, I will repay," and when neither crucifixions nor hanging shall be known any more for ever.

**BOOK NOTICES.**

As in former years, the volume of the "Obstetrical Transactions" for 1882 contains, along with many valuable papers and formal discussions, a great number of brief but interesting accounts of anatomical and morbid specimens and therapeutic devices shown at the meetings. Much of its contents has appeared in the different journals, and at various times our readers have been given a summary of portions of the proceedings as they were brought out by our English contemporaries; but that will not diminish the interest of the volume for those who wish to follow the progress of obstetrics and gynecology systematically, or their desire to possess the consecutive volumes.

The following were among the more noteworthy proceedings of the society during the year: An adjourned debate on Dr. Godson’s paper on the Treatment of Spasmody Dysmenorrhea and Sterility by Dilatation of the Cervical Canal with Graduated Metallic Bougies; a case of retention of menstrual fluid in one half of a double uterus, by Dr. Alfred L. Galabin; the Annual Address by the President, Dr. J. Matthews Duncan; a paper by Dr. W. S. Playfair, on Emmet’s operation (tracheloraphy), or, as Frenchified by the author, (trachélo-raphé); a successful case of laparotomy for extra-uterine pregnancy, by Mr. J. Knowsley Thornton; a paper on the corpus luteum, by Dr. W. A. Popow, of Pensa, Russia; an essay on the natural history of dysmenorrhea, by Dr. John Williams; an adjourned discussion on Dr. Williams’s paper; a paper on the relation between backward displacements of the uterus and painful menstruation, by Dr. G. Ernest Herman; an account of a case of obliquely contracted pelvis in a child with nero-ilia syno-dosis on one side, with remarks on the pelvis of Nægæle, by Dr. Francis H. Champneys; an analysis of several cases of interstitial pregnancy, by Mr. Alban Doran; a description of a kyphostic pelvis, with remarks on Bresky’s description, by Dr. Champneys; a paper on puerperal diabetes, by Dr. J. Matthews Duncan; and a paper on the treatment of post-partum hemorrhage by means of hypodermic injections of ergotin, by Dr. C. Chabazza, of Paris.

Perhaps our readers will be most interested in Dr. Playfair’s paper. Although it deals with the merits of a procedure that now finds few opponents in this country, and has practically ceased to be the subject of discussion, except as to minor matters of detail, it is always well to review our conclusions, however settled they may be, in the light of what is thought of them elsewhere. We must say, however, that in the discussion there was a good deal of random talk, together with not a little of dilapidant reasoning from premises so erroneous as to seem grotesque. It is certain, however, that the English are "stirred up" in regard to Emmet’s operation, and it may be inferred that they will not let it alone until they have come to view it in its right light.

**BOOKS AND Pamphlets RECEIVED.**

A History of Tuberculosis, from the time of Sylvius to the present day. Being in part a translation, with notes and additions, from the German of Dr. Arnold Spina. Containing also an account of the researches and discoveries of Dr. Robert Koch and other recent investigators. By Eric E. Sattler, M.D. Cincinnati: Robert Clarke & Co., 1883. Pp. 191.

Announcement and Catalogue of the National Medical College (Medical Department of the Columbian University), Washington, D. C., for the sixty second session, 1883–’84.

The Canadian Frontier, according to Dr. James E. Reever, of the State Board of Health of West Virginia, constitutes a wide door of entry for infectious diseases, and a very dangerous one, "because it cannot be guarded by United States authorities; hence the possibility that cholera may first attack the lake cities—Buffalo, Chicago, Milwaukee, and Detroit, and spare meanwhile New York, Philadelphia, Baltimore, and other cities on the Atlantic seaboard."
GERMICIDE INHALATIONS IN THE TREATMENT OF CONSUMPTION.

The "Australian Medical Journal" for April, 1883, contains a report by Mr. G. Lydiard upon the "Particulars and Method of using the Carbolic Spray for the Cure of Sheep affected with Lung Worm." A fumigating house, built specially for the purpose, was as air-tight as it could be made. In it there were two rooms each thirty-three feet long, seventeen feet wide, and six feet and a half high, affording capacity for three hundred lambs. The solution of carbolic acid to be sprayed was first made of a strength of 1-30, afterward 1-20. Subsequently the "Calvert's carbolic No. 4," in proportion of 1-1, was used. The spray, produced by compressed-air machinery, was thrown into each room by four jets. It was so fine that it mixed at once with the air, scarcely any falling to the ground in a mist. One pint of carbolic acid was used to each room. When the spraying began, the sheep moved about a little, but soon became quiet, and stood with their eyes shut, chewing the cud. They were kept in the spray half an hour. No sheep have been lost by the process; on the other hand, they almost ceased to die from the lung-worm disease, and rapidly improved in condition. Mr. Lydiard found no difficulty himself in breathing in the room filled with spray, but felt a tickling all over his face, which likened to the pricking of needles. He was obliged to shut his eyes. Pure carbolic acid was used in some of the worst cases.

Mr. Lydiard's report was read and discussed at a meeting of the Medical Society of Victoria (Australia), with reference to its bearing on the treatment of tubercular phthisis. The report showed that a carbolic-acid spray of sufficient strength to destroy the Strongylus filaria, a worm from half an inch to an inch in length, lying free in the air-tubes, could be inhaled with impunity for a time by man or beast. While these facts do not prove that the bacilli of phthisis can be destroyed in a similar way, they indicate the possibility of such a thing, and suggest the propriety of further experiments so conducted as to determine with more certainty what can and what cannot be accomplished in tubercular and other forms of phthisis by such inhalations. It is still disputed whether the bacilli are a cause or a result of tubercular phthisis. By some it is contended that they are the prime cause of the formation of tubercle; by others, that they simply aid in the softening and breaking down of tubercular deposits; by still others, that they have no causative action either in the formation or softening of tubercle, but merely find in a tubercular lung conditions favorable for their own growth and propagation. Some observers hold that the germs are locked up within the non-vascular tubercle in such a manner that the spray of carbolic acid, or any similar agent, could not penetrate to them, much less destroy them. But, while theoretical objections are not wanting, none of them should prevent proper experimentation to test more thoroughly the value of carbolic and other germicide spray in the treatment of tubercular phthisis. It is well to bear in mind that the process so successfully employed in the case of Mr. Lydiard's sheep is not based upon the use of inhalers, but on the placing of the diseased animals in an atmosphere permeated with a spray, regulated as to its strength and other characteristics by successive trials, to meet the needs of the special form of disease for the relief of which it was resorted to. It seems that a spray in which the particles are very finely divided can be inhaled of much greater strength than one in which the division is not so fine. Moreover, the hygroscopic condition of the air must make no little difference in the fineness with which the spray can be made and maintained. This and all other conditions affecting the nature of the spray, and therefore its adaptability to the end in view, should be carefully taken into consideration. Though germicide inhalations may never amount to a specific cure for any form of phthisis, if they can be made to assist in the relief of symptoms, in the arrest of the disease, and therefore in prolonging life, they will prove a great blessing to a large class of those who suffer from the ravages of the disease.

Some have decried all treatment by inhalations, on the ground that they must be difficult if not impossible for the physician to carry out, and irksome, if not unbearable, for the patient. Such objections, after all, are not of much moment. The real question is as to the efficacy of the treatment, and this can be decided, not by a priori reasoning, but by proper experimentation alone.

THE HEALTH OF THE NAVY.

It is seldom that a "blue-book" is found so replete with information of practical value to students of sanitary science and to medical statisticians as the "Sanitary and Statistical Report of the Surgeon General of the Navy for the year 1881," just issued from the Government Printing Office. While it is nothing new for the medical corps of the navy to do good service in advancing the art of medicine, the volume in question must certainly be looked upon as one of the chief evidences of the many given by Surgeon-General Wales of his eminent fitness for the office he holds, and of his faculty of guiding the work of his corps in such manner as to make it of the greatest availability for the purposes of medicine in general, as well as for the preservation of the present satisfactory state of the health of the navy.

The report deals not only with the general sanitary condition of the force, but with that of the various squadrons, and even that of each individual vessel and shore station. Under these headings elaborate tables supplement the text. Of the entire force, 14,013 persons came under medical treatment during the year, including 469 whose treatment was continued from the preceding year: 400 of these were still under treatment at the close of the year, 97 died, 368 were invalided from the service,
1,845 were invalided to hospital, and 11,863 recovered. The total loss of time occasioned by injury and disease amounted to 166,927 days. Compared with the figures of the preceding year, the number of persons under treatment was increased by 626, and the number of those invalided to hospitals by 555; but 13 fewer were invalided from the service, the time lost was 12,508 days less, the deaths were fewer by 14, and the daily average sick-rate and the average duration of treatment were considerably reduced. This showing is highly creditable to the medical corps.

In the enumeration of diseases, the nomenclature of the Royal College of Physicians, of London, is adhered to in the main. This we can not approve of. The nomenclature is pedantic and open to various objections that we have not space to allude to at present. Not the least of them is its tendency to do away with the safeguard against error that the use of the more ordinary terms would supply. A striking illustration of this is to be found in the statement, in the report under consideration (p. 8), that nine boys were among the victims of "senectus!" Undoubtedly this is a typographical error, evidence of which is found in the fact that one man and nine boys appear in the table as making a total of thirteen, but it is safe to say that the use of a term more readily comprehensible by the proof-reader than senectus would have led him to call attention to the mistake.

THE SCIENTIFIC WORK OF THE NAVAL MEDICAL CORPS.

The same report furnishes the most gratifying proof of the pains taken by the medical officers of the navy to do creditable scientific work, while not neglecting the daily duties of attendance on the sick. We have on various occasions mentioned this devotion of the corps to investigations calculated to aid in the advance of medicine. That the data recorded in this volume have been worked out under all the disadvantages incident to a reduction of allowances, in some instances so great as fifty per cent. from the estimates, can but add to our admiration. The Government can scarcely afford to cripple the performance of such important work by stinginess in the matter of appropriations.

Among the scientific contributions to the volume is a continuation of Passed Assistant Surgeon Streets's experimental investigation of the organisms contained in the dust of the air, with excellent heliotype prints of microphotographs of the Bacillus subtilis, and the Bacillus robor (Cohn). This is followed by an account of the sanitary survey of a proposed site for the new Naval Observatory, by a board composed of Medical Director J. M. Brown, Surgeon J. H. Kiddler, and Passed Assistant Surgeon S. H. Griffiths. This includes a consideration of the topography, the buildings, the water supply, the drainage, and the soil. Well-executed heliotypes are given of various organisms found in the sediment of the well water and obtained by atomization of the ground air. The board came to the conclusion that the selection of the site was a fortunate one.

In the sections devoted to the various squadrons, topographical and sanitary reports are given in regard to numerous localities that will always have to be taken into consideration in our naval hygiene. Of the North Atlantic Squadron, Surgeon G. F. Winslow, of the Vandalia, reports upon Barbadoes, Trinidad, Antigua, Puerto Cabello (Venezuela), St. Pierre, Fortune Bay, St. John's (Newfoundland), St. John (New Brunswick), Hamilton (Bermuda), and Basse Terre (St. Kitts); Passed Assistant Surgeon H. C. Eckstein, of the Alliance, upon Reykjavik, Hammerfest, Spitzbergen, and West Spitzbergen; and Passed Assistant Surgeon H. Aulick, of the Despatch, upon Samana and San Juan (Puerto Rico).

Of the South Atlantic Squadron, Passed Assistant Surgeon F. B. Stephenson, of the Shenandoah, reports upon Port Castries, Curacao, and Carthagena. Of the Pacific Squadron, Surgeon C. H. White, of the Lackawanna, reports upon Juan Fernandez, the Marquesas Islands, the Society Islands, and the Samoan Islands.

Of the European Squadron, Medical Inspector B. F. Gibbs, of the Lancaster, reports upon Gibraltar; Medical Inspector J. C. Spear, of the Trenton, upon Marseilles and Funchal; Surgeon G. S. Beardsley, of the Galena, upon an earthquake at Chios; and Surgeon J. W. Coles, of the Nipsic, upon Stockholm and Christiania.

Of the Asiatic Squadron, Passed Assistant Surgeon B. F. Rogers, of the Richmond, reports upon Papete and Upolu; Passed Assistant Surgeon G. E. H. Harmon, of the Alert, upon various Japanese and Chinese towns; and Passed Assistant Surgeon F. H. Terrill, of the Monocacy, upon his observations in Japan and Corea.

Finally, an elaborate and exceedingly valuable Report on the Pharmacopoeias of all Nations, by Surgeon J. M. Flint, calls for more comment than we are able to give it in the limited space now at our command. We have, indeed, been able to do little more than mention the many important scientific contributions contained in the volume. We trust that the edition is large enough to admit of its being distributed freely among public libraries where it will be accessible to the profession.

THE AMERICAN MEDICAL COLLEGE, OF ST. LOUIS.

We have received a communication from the dean of the college, Dr. George C. Pitzer, in which, referring to an account of the annual meeting of the State Board of Health of West Virginia that appeared in our issue of July 21st, he says:

"The American Medical College is a reputable institution. No college in the West stands better with home authorities than this. Its hospital and clinical privileges, as conferred by the Board of Health of St. Louis, are the same as other colleges, and have never been questioned. We ask you to give place to this answer, and herewith furnish the curriculum of the American Medical College, that your readers may know the requirements of this institution.

"[Fee and Requirements for Admission.—A good elementary English education, including Mathematics, English Composition and Elementary Physics, or Natural Philosophy, as attested by the presentation of a diploma, from some literary and scientific college or high school, or by creditable examination upon those branches by a committee appointed for that purpose. Ticket for One Session, including all departments, $75.00. (Matriculation and Demonstrator's ticket included in the above.) Preliminary Course, Free. Hospital Tickets, Free. Graduation Fee, $25.00. Scholarship Ticket, including Graduation
MINOR PARAGRAPHS.

CHOLERA.

A like favorable account may be given of the cholera. It has not yet spread beyond Egypt, and even in that country its prevalence is much diminished and the percentage of deaths among those attacked has fallen notably. But these facts afford but a slender basis for the newspaper talk to the effect that the Egyptian outbreak was really not one of cholera, but of "choleric fever." Dr. Reeves, of the State Board of Health of West Virginia, having called attention to the danger of the disease creeping into the United States from Canada, in case it should spread over Europe, it is satisfactory to learn that the sanitary officials of several of the frontier States are impressed with the need of taking all possible precautions. A number of cargoes of Egyptian rugs are still on their way to this country, but there is reason to believe that they will be dealt with properly at all our ports. Particularly energetic measures in this regard have been resolved upon in Boston, which is, perhaps, of all our ports the one most exposed to this special source of infection.

YELLOW FEVER.

Thus far, the precautions taken by the Surgeon-General of the Marine-Hospital Service, by the sanitary authorities of our ports, and by the Sanitary Council of the Mississippi Valley, have prevented the disease from effecting a lodgment on American territory. The work of these various officials has now been reduced to such a system that there seems to be very little ground for anxiety. This, however, should not lead to any relaxation in its execution.

TYPHUS.

As typhus is quite prevalent in Liverpool, a port with which New York is in constant communication, the importance of guarding against an importation of this disease should not be obscured by the greater attention devoted to cholera and yellow fever by reason of their comparative rarity. In this matter, however, much may be trusted to the sanitary inspections of vessels in British ports made in behalf of our Government.

THE CHEASPEAKE BAY QUARANTINE.

The pilots of Chesapeake Bay having been stupid enough to recommend the transfer of the quarantine station from the Capes to the York River, it has remained for an official of a transportation company to point out the hazards that such a change would bring to passengers on the steamers plying regularly between points on that river and the port of Baltimore, as well as to the people living along the river. It is to be hoped that no class interests will gain popular support in opposition to the work of the Marine-Hospital Service.

CONTAGIOUS PLEURO-PNEUMONIA ON STATEN ISLAND.

In a recent vigorous communication to the "American Dairyman and Stock Breeder," Dr. A. S. Heath, of this city, Lecturer on the History and Breeding of Domestic Animals, at the Columbia Veterinary College, calls on the State Board of Health to suppress the nefarious business of one Meyerbaum, who buys, sells, and slaughters sick cattle at Linoleumville. It is suggested that, when the cows get too sick for traffic in their milk to prove profitable, they are butchered, and their carcasses are sold to butchers of "Bologna" sausages. It is thought that Meyerbaum's place is undoubtedly a perennial source of infection. Inasmuch as a member of the board lives on Staten Island, it certainly seems as if the matter ought to stand a fair chance of being attended to.

THE BUFALINI PRIZE.

In accordance with the will of the late Professor Bufalini, a prize of 5,000 d. will be awarded for the most meritorious essay on the application of the experimental method in the sciences. Manuscripts, which must be in Italian or Latin, will be received until October, 1884. They should be sent to the Secretary of the Faculty of Medicine and Surgery of Florence.
NEWS ITEMS.

THE NEW YORK POST-GRADUATE MEDICAL SCHOOL.—Dr. Andrew H. Smith has been elected a Professor of Clinical Medicine and Therapeutics, and Dr. Alexander J. C. Skene, of Brooklyn, a Professor of Gymnology—not to fill vacancies, but to serve in conjunction with the present occupants of those chairs.

THE BALTIMORE MEDICAL COLLEGE.—The "Maryland Medical Journal" announces that Dr. G. Halstead Hoyland has resigned the professorship of surgery, and that the vacancy has been filled by the appointment of Dr. G. Glauville Rush, of Baltimore.

DARTMOUTH MEDICAL COLLEGE.—We learn from the "Boston Medical and Surgical Journal" that Professor O. P. Hubbard has resigned the chair of chemistry, after forty-seven years of service, and has been made professor emeritus; that Professor Edwin J. Burdett will give the course in chemistry during the present session; and that $2,000 have been received from the estate of the Hon. E. W. Stoughton for the benefit of the Museum of Pathological Anatomy.

THE TSOLCOURSE SCHOOL OF MEDICINE.—M. Caubet, Professor of Internal Pathology, has been appointed director of the school for a period of three years, in place of the late M. Filliol.

A NEW MEDICAL COLLEGE.—The "Pittsburgh Medical Journal" states that a charter has been obtained for an institution to be termed the Pittsburgh Medical College, but adds that preparations have not been completed for its organization.

THE PARIS ACADEMY OF MEDICINE.—M. Lannelongue has been elected a titular member of the section in surgical pathology. Of the eighty-two votes cast, he received eighty-four, M. Pian twenty-six, and M. Terrier one, the remaining ballot being blank.

THE MASSACHUSETTS STATE BOARD OF HEALTH, CHARITY, AND LEANCT has appointed Dr. A. B. Heath, heretofore the Post-Doctor of Boston, to be a medical inspector, in place of Dr. William L. Richardson, resigned. Dr. Arthur G. Griffin succeeds Dr. Heath as Post-Physician.

THE CONNECTICUT MORTALITY RETURNS FOR JUNE, for which we are indebted to the secretary of the State Board of Health, show an increase over the usual rate for the month, amounting in Hartford to as much as forty per cent. The excess is not due to the special prevalence of any one class of diseases.

PROFESSOR H. NEWELL MARTIN, of the Johns Hopkins University, Baltimore, has been appointed the next Oronoan lecturer of the Royal Society of London.

PROFESSOR OSLER, of McGill University, Montreal, says the "Canada Medical Record," has been elected a Fellow of the Royal College of Physicians of London.

THE ASTLEY COOPER THEATRICAL PRIZE of £300 has been awarded to Dr. William Alexander, of Liverpool, for an essay on "The Pathology and Pathological Relations of the Disease known as Osteo-arthritis, or Chronic Rheumatic Arthritis."

A FEMALE PHYSICIAN IN ROME.—According to the "Deutsche Medicinal Zeitscb" the widow of Prof.-or Boll, who is a daughter of Traube, has been made a doctor of medicine in Rome.

THE AMERICAN NATIONAL ASSOCIATION OF THE RED CROSS.—The President of this Association, Miss Clara Barton, Superintendant of the Female Reformatory at Sherborn, Massachusetts, is making preparations to meet the exigencies which may arise from an invasion of this country by cholera or yellow Fever. Dr. J. B. Hubbell, of Cedar Rapids, Iowa, her special field agent, has been ordered to report to her in person, and everything is being made ready for immediate action in case of necessity. The Association has at present about $15,000 available funds.

A BURIAL WITHOUT A PERMIT has recently come to light in this city—an occurrence deemed almost impossible, in view of the stringent provisions of the sanitary code. As a death certificate had been given, the issue of a permit is said to have been taken for granted by the keeper of the Morgue, and by his direction a pauper burial was given the deceased. An organization to which the latter belonged has exhume the body, and buried it in Calvary Cemetery.

OBITUARY NOTES.

PROFESSOR PACINI, of Florence.—Filippo Pacini, the distinguished discoverer of the Pacinian corpuscles, died on the 8th of July at Florence, in which city he held the position of Professor of Topographical and Microscopical Anatomy in the Istituto di Perfezionamento. He was in his seventy-first year.

JUTSON GILMAN, M. D., of BALTIMORE.—Dr. Gilman died on Wednesday, the 1st inst., in his sixty-fifth year. He was born in Meredith, N. H., and received his preliminary education in Roxbury, Mass., and his collegiate at Colby University, Maine, and in 1845 graduated from the Medical Department of the University of Maryland. Dr. Gilman was prominent in the medical societies of Baltimore, in some of which he held the offices of president and treasurer for a number of years. He was a United States Army surgeon in the field in 1862–63, and from October, 1863, until the close of the war, he was Acting Assistant Surgeon in hospitals at Point Lookout.

N. G. RIDGLEY, M. D., of BALTIMORE.—We learn from the "Maryland Medical Journal" that Dr. Ridgley, who served in the Confederate army during the late war, died in Baltimore on the 4th of July, at the age of forty-two.

EDWARD MEAD, M. D., of BOSTON.—Dr. Mead is reported to have been lost at sea by the wreck of the Portuguese barque Pimpaio, on the coast of Pico, on the 28th of June, he being the surgeon of the vessel. He was born in England in 1819, and came to this country in 1832. In 1841 he received the degree of doctor in medicine from the Medical College of Ohio. He made psychiatry his special study, and was connected with several private asylums at different periods. He was a member of the Massachusetts Medical Society.

Letters to the Editor.

IS THE CODE CONTROVERSY A CASE OF TWO MEN AND THE SHIELD?

BUFFALO, August 2, 1883.

To the Editor of the New York Medical Journal:

Sir: The appearance of an article entitled "What is a Consultation?" in the "Ephemeris" for July led the writer to make a review of the code controversy literature, which brings him to the conclusion that the heat of the discussion is the result of a misconception upon the part of the supporters of the old code of the wishes and motives of the new code party—that the former were ready to die in the last ditch rather than submit to the establishment of certain relations between the profession and
the homoeopathists, which relations the latter never thought or
desired to establish.

The irate last-ditchers have been ready to die daily rather
than do that which no one ever thought of asking them to do;
and it would also seem that the pestilent introducers of irritat-
ing innovations, who seek with their new notions to break up
the time-honored usages of the profession, have been quite mis-
taken in regard to the liberal and catholic spirit of the code of
the American Medical Association.

All this confusion and noise, this passing up and down of the
 canvasser, this pledging or refusing to be pledged, this throttling
or trying not to be throttled, this iron-clad oath which each
must take or go home with the fear that he is not quite regular
—all this has been, and is, and is yet to be, because the parties
would not take the pains to look at a certain object from a com-
mon ground, but would go on with the old contention, "I say it
is red," and "I say it is blue"—the only variation from the
fable being that each insisted in naming the color, not of his
own, but of the other man's side of the shield.

Your correspondent, seeing something of this inclination, in
a discussion of the subject reported in the "Buffalo Medical and
Surgical Journal" for September, 1882, page 74, gave the other
man this invitation to step across and look at the matter from
his point of view:

Before concluding, I must remark, in passing, upon what seems to
be a unanimous misconception of the supposed action of the code of
1888.

It would seem from the reports of all the official actions and most
of the individual utterances upon this subject, from the august Ameri-
can Medical Association down to the humblest local medical society,
that the logical action of the code of 1882 is to recognize homoeopathy,
Hahnemannism, infinitesimalism, and all the allied delusious. That
to meet a man in consultation is to extend to him full fraternal recog-
nition, to undertake to confirm his diagnosis and to support his treat-
ment.

This seems to be the popular conception of the action, and the only
possible action, of our new code; and I wish simply to remark that
nothing could be more false or misrepresenting. To my mind the ac-

tion of the new code is: first, to say to the people, we bow in acquies-
cence to your authority and recognize the homoeopathists as physicians;
second, to say to the homoeopathists, we will meet you where and
when you will, and treat you with exact fairness and justice, recogniz-
ing that consultation is for the benefit of the patient, and that in case
we disagree, as we are likely to, regarding diagnosis and prognosis, and
are sure to about treatment, we will be governed by our code for such
cases made and provided. That legal recognition and consultation mean or necessitate full fraternal recognition and relationship, I am
sure never for a moment entered the minds of the framers or advocates
of our new code. The general impression seems to be, that willingness
to consult implies on our part all the rest; to my mind it simply im-
plies formal official recognition of the relations of the homoeopathists
to the State. We accept their credentials and allow the developments
of the future to decide whether their relations to us will ever be more
than formal recognition. The laws of the State, the temper of our
people, and the genius of our institutions demand this, but, as we are
not allowed to prescribe them for opinion's sake, they can not coerce
our indorsement of their doctrines.

Your correspondent is not aware of any one having accepted
this invitation, but the object has been accomplished by differ-
ent means; the other man has taken occasion to tell, not of our
own, but of the color of his side, and in faith it is just like ours,
as any one can see.

Dr. E. R. Squibb, in the article above referred to, says:
If a surgeon or other specialist be sent for by a patient or by an
irregular physician, and treats any special case by his own skill and
principles and judgment—no matter whether the irregular continues to
see the patient or not—is that a consultation? Certainly not, for
there is no council held, and no violation of principle, but, on the other
hand, there is a triumph of principle against which want of principle
can not long stand, for honesty, truth, justice, and humanity all under-
lie and support such action, and therefore the old code supports it.

Is a practitioner when summoned, whether in emergency or not, to
stop to inquire whom he is to meet at the bedside in order to avoid heter-
egeneous consultations as if he were mortally afraid of them? Cer-
tainly not, since even the meeting with irregulars does not constitute consultation with them; and if he meets them and does his best for the
patient, without admitting professional fellowship, and without holding
himself, or permitting the appearance of holding council, and holding
consultations with the patient a free choice as to whom he will choose to conduct
his case, and stating the plain reason why he can not have both, there
is no consultation and no conflict with the old code of ethics.

If a physician is sent for to meet one or more irregular practitioners
in consultation upon a difficult or critical case, must he decline the
meeting? Certainly not. He may go. And perhaps, if his sense of
moral rectitude and justice be very high, he may decide that he must
go. But he will most certainly decline consultation when he gets to
the meeting. He will make clear his readiness to see the patient if
that be desired, and to do the very best he can for him; but he will
distinctly decline to do this jointly with those whose avowed or tacit
principles of action are so antagonistic to his that one side only can be
the right. If the patient or friends insist in the name of humanity,
and for the sake of a beloved child or relative, that he should remain
in joint management, and assist by his counsel and experience, is he
then justified in such consultation? No; for if he can not make the
patient and friends understand that the presence of either the regular
or the irregular practitioner must, in the nature of cause and effect, be
detrimental to the interests of the patient, then he must withdraw
by the force of his own principles of probity and honor, and submit to
popular adverse criticism, and even newspaper misconstruction and
abuse, if need be. But first he will earnestly strive to convince the
patient that either course of treatment is surely better for him than any
admixture of incompatibles.

If at the request of a patient or friends a regular practitioner takes
charge of a case, and an irregular practitioner is, by the family, re-
tained in attendance, even if visiting the patient at the same hours, or
present at the treatment, is this a consultation? Not if there be no
holding council to deliberate upon the case—no acknowledgment of a
joint responsibility, no admission to professional fellowship and equal-
ity, nor any admixture of treatment. The irregular is then not a con-
sultant, but a spectator, or may even be a nurse.

The line is not difficult to draw in any of these cases, and although
it will not be exactly the same line as drawn by different individuals
and under different circumstances, yet it will always be coincident in
effect if drawn in obedience to the plain rules of honor and honesty
and the plain meaning of words. And, if it be carefully drawn with
that unselfishness which first thinks of the feelings of others, it will
always be done with politeness and courtesy.

To the writer this view of the code of the American Medical
Association is as new as it is satisfactory, and if this is the cor-
rect construction no other code is needed.

Although, from the dignity of his character and the propriety of
his methods, Dr. Squibb can be cited as the professional lead-
er of the old code party in this State, yet his interpretation is
only that of an individual.

To make the matter complete, it is necessary for his con-
struction to be ratified by the judicial council of our national
association.

In case that body should feel a hesitancy about acting upon
such an important matter, without the same being first referred
to it from the association at large, it will only be necessary for
the council to recall the action taken before the late meeting at
Cleveland, regarding the iron-clad oath, to discover a perfect
precedent for that required in this case.

By all means let us hear from messieurs the judicial council.

H. R. Hopkins.
Proceedings of Societies.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A stated meeting was held February 24, 1883, Dr. T. Gail-
lard Thomas, President, in the chair.

Acute Mania relieved by Anti-syphilitic Treatment.—Dr.
F. N. Otis related the case of a young man under his care as
follows: The patient had been abroad, and had probably led
a somewhat dissipated life, but on his return was in an excellent
state of health. Shortly afterward, however, he showed symp-
toms of acute mania; two prominent alienists pronounced his
case one of commencing paresis, and gave a very unfavorable
prognosis. After remaining in Bloomingdale Asylum several
weeks, contrary to expectation he became quite rational, and
then said that he had been undergoing a course of anti-syphilitic
 treatment, and within a short time a syphilitic papular eruption
developed. He had now perfectly recovered from cerebral symp-
toms. There was enlargement of the lymphatic glands. Dr.
Otis remarked that he had seen several cases in which the papu-
lar eruption of syphilis had given rise to disturbances in differ-
ent parts of the body which seemed to be due to the presence
of a papule, or an accumulation of cells of which it had been
proved, papules consisted, at some place within the body. Such
an accumulation of cells was seen to occur sometimes under the
periosteum of bones, constituting nodules. Apparently the same
thing occurred also in the anterior chamber of the eye, and
seemed to be connected with the iris, constituting a condition
called by oculists gummy tumor of the iris. These tumors
passed away under the same general treatment that was adapted
to the active stage of syphilis. He had also seen a case in which
an acute attack of jaundice developed in connection with the
papillary stage of syphilis, and disappeared with the disappearance
of the syphilitic symptoms.

Dr. A. Clare asked Dr. Otis if he attributed the recovery
from the cerebral symptoms in this case to treatment with mer-
cury.

Dr. Otis replied that he did, and that the principle of the
cure was that the drug had caused an absorption of the papillary
material, if one chose so to call it, that had probably been de-
posited in the membranes of the brain and which had given rise
to symptoms by pressure.

The President asked Dr. Otis if he thought his patient
would entirely recover from syphilitic disease.

Dr. Otis replied that he thought he would; he saw no rea-
son why he should not. It was an ordinary case of syphilis
which happened in the first stage to develop this peculiar con-
istutional phenomenon, which was no more likely to occur in a
severe case than in a mild attack. There was no reason, so far as
he knew, why a papule should not develop at some point in the
central system, and give rise to corresponding phenomena, than
that it should not develop at a superficial point of the body.

Dr. A. C. Post remembered to have once seen a case of
inherited syphilis in a young child about six months old, with
enlargement of the head, apparently from hydrocephalus, and
with a certain amount of stupor and strabismus. The child was
relieved by mercurial injection.

The President asked Dr. Otis whether he had ever known
a case of constitutional syphilis which was cured in the early
stage never to manifest symptoms afterward.

Dr. Otis replied that he thought it was of very common
occurrence. He believed that the majority of cases of syphilis
never manifested tertiary symptoms. This was particularly
true where treatment had been begun early after contraction of
the disease. It was only exceptionally that we met with a typi-
cal case of syphilis, where the patient went through all the
stages of the disease. He had made some observations recently
which demonstrated a tendency on the part of the papule to
reappear at the same place a number of times. In one instance
it was observed to return eight or ten times. Probably the
part had become more vulnerable from the appearance of the
papule on previous occasions.

Dr. B. W. McCready mentioned the case of a man who,
about thirty-five years ago, contracted syphilis and married be-
fore the primary lesions were entirely recovered from. The
first child from the marriage was weakly, the teeth and the
nails were badly formed, indicating hereditary syphilis. The
child, however, lived to grow up, and was apparently in perfect
health to-day. Several other children were born, and died
before the end of the second year, two of them of hydro-
cephalus. There was one delicate girl, and another child well-
built and strong. In the meanwhile the father had become per-
fectly well, and was still an active man. The mother was stout
and well. In another instance a small, active, nervous man,
of excellent health, married a very healthy woman, who gave birth
to a boy and a girl. The boy, who was delicate, contracted
bad habits, and died in early life; the daughter was delicate,
excessively nervous, married, and died rather suddenly. The
father also died, perhaps indirectly of alcoholism. On furthering
into the family history, Dr. McCready learned, through
Dr. Bumstead, that the father had suffered from syphilis, to
which Dr. Bumstead attributed the weakly condition of the
children.

Dr. Otis remarked that physicians and patients were very
prone to look up a syphilitic history whenever anything oc-
curred which they were not able to understand; and, if the
least evidence of the existence of syphilis in the family were
obtained, everything was made clear. If no evidence of syphi-
lis was obtained, then the case was put down as one of struma,
or some mysterious hereditary taint not syphilitic. He believed
these cases to be so entirely opposed to all that we know posi-
tively with regard to syphilis, and had been so indefinitely re-
ported, that they could hardly be brought forward as evidence
of much value in determining that such constitutional peculiari-
ties were due to the effect of this disease. Fournier, in his work
on "Syphilis and Marriage," related a case which he believed
illustrated the fact that in some instances syphilis could be com-
unicated in an active form years after the manifestation of
primary symptoms, and the entire foundation of the case rested
solely on the supposed fidelity of a mistress to her master.
Such and similar evidence could not be accepted upon which to
base so important scientific conclusions. On the opposite side,
however, Fournier had reported eighty-five or eighty-seven
cases which had come under his observation, showing that the
disease became entirely eliminated from the system, so far as
its power of contagion was concerned, after the lapse of a
considerable length of time. In some of the cases marriage was con-
tracted from a year and a half to five years after the first lesions
of syphilis manifested themselves, and the disease was not com-
nunicated to the wife or to the children.

Dr. McCready remarked that while in the case which he
reported syphilis may not have been transmitted in an active
form to the children born after the lapse of some years from the
contraction of the disease on the part of the father, yet it prob-
ably had such an effect upon the parent's constitution that
offspring of an imperfect organization was the result.

Dr. Otis remarked that there was a difference between in-
erited syphilis, the result of a contagious principle, and an
inherited weakly condition of the body as a sequel of the disease.
It was well known that women who had had syphilis might
give birth to miserable, unhealthy, deformed children, the
PROCEEDINGS OF SOCIETIES.

[Dr. A.]roceedings

A blood-clots to Application of Fourth to who in the examination of a syphilitic patient. Other symptoms of the disease manifested themselves, and later, partial paraplegia.

Poisoning with Illuminating Gas treated by the Inhalation of Oxygen.—Dr. Alonzo Clark reported two cases, an account of which will be found on p. 148.

Dr. Post remarked that a patient was brought to the Presbyterian Hospital during the past year suffering from poisoning by illuminating gas, and during a consultation of the physicians the question of the administration of oxygen was raised, and was objected to on theoretical grounds the exact nature of which he did not remember. It was not administered, and the patient died shortly after admission.

Dr. H. B. Sands asked Dr. Clark whether he knew what kind of illuminating gas had been inhaled by the patient.

Dr. Clark replied that he did not; the patient lived in Fourth Street.

Dr. Sands said he had been told recently, by a gentleman who was familiar with the process of making gas, that the so-called water-gas was far more poisonous than the ordinary kind (containing the oxide of carbon in large quantity).

Possible Etiological Relation of Cancer to a Simple Application to the Cervix Uteri.—The President related the following case: A week ago he was called to see a lady, whose history was given by her physician as follows: He was called to see the patient three months before. She was in good health, and had sent him simply because of a slight leucorrhoea. She was about thirty-eight years of age, and had given birth to children. The doctor, on introducing the speculum, found a gluttonous discharge coming from the cervix, which he supposed to be due to ordinary cervical leucorrhoea. He introduced a small cotton tampon, with a thread attached, dipped into a solution of nitrate of silver, twenty grains to the ounce, packing it in about the cervix, allowing none of the fluid to come in contact with the vaginal wall. The patient complained afterward of a burning pain, but, by the advice of her doctor, allowed the tampon to remain in place until he was about to leave the house. The pain was then so severe that she withdrew the tampon. Returning again in the evening, the doctor found the patient walking the floor, in intense agony, and suffering from a desire to make urine, of which only a few drops mixed with blood passed at a time. She said that after he had left the house the burning pain of which she had complained steadily grew worse. Opisthes in large quantities were administered, and the vagina was syringed out frequently with water. He told her that the symptoms would pass away by morning. But, being sent for the next morning, he found acute inflammation of the vagina and of the urethra, and a good deal of cysitis. The urine was passed every hour. Dr. Thomas said that this condition of things had lasted up to the present time—a duration of three months. The patient had become emaciated to an extreme degree, having lost about thirty pounds. As the case advanced, she was taken with violent pain in one hip, which extended downward, and for the relief of which large quantities of opium had been taken during the past four months. When Dr. Thomas examined the patient, he found the posterior lip of the uterus entirely destroyed by cancer. There was nothing specially interesting about the case, except the remarkable coincidence of an acute attack of vaginitis, urethritis, and cystitis being immediately followed by cancer of the cervix.

Dr. Thomas remembered that one of the most violent attacks of vaginitis that he had ever met with was due to one or two drops of a saturated solution of chloric acid, which was being applied to the cervix, coming in contact with the vaginal mucous membrane. The attack lasted for three or four weeks, and the patient being a very nervous woman, he was much alarmed as to the final result.

Dr. Sands asked the President whether he thought cancer would have developed in this case had the acid application not been made.

The President replied that he certainly thought it would. He had never seen a case of cancer develop from even a most violent attack of vaginitis, nor from any other acute inflammation.

Cancer Developed from a Non-malignant Soke.—Dr. Sands said that a man came to his college clinic in the early part of last autumn to consult him with regard to a swelling of the neck, which, he said, had immediately followed an injury received some weeks before in a scuffle. On the next morning after sustaining the injury he perceived that his neck was swollen, which swelling persisted. Dr. Sands found a swelling on the left side of the neck, at about equal distances from the upper and the lower limits, the nature of which he was puzzled to understand. The swelling was of the size of a large almond, fluctuated, and yet did not seem to be an abscess. The man was quite sure that nothing was the matter with him before this injury had been received. It was probably a hematoma. The man went to the hospital, the tumor was aspirated, and about an ounce of serum streaked with blood was withdrawn. The swelling reappeared, and a week later an incision was made with the knife; blood-clots were removed, together with the thickened cyst-wall, which seemed to have been due to an inflammatory deposit covered by thick layers of lymph. A strong solution of carbolic acid was applied, a drainage-tube was inserted, antiseptic dressings were applied, and the case did well for about a month. At the end of that time he got up, and intended to go out of the hospital, but was seized with a chill, and, on examining the neck, it was found that the wound had not closed, and on the following day Dr. Sands enlarged the opening, and found a considerable quantity of pus. From that time there was a repetition of chills at frequent and irregular intervals, which led him to suspect pyemia, but they proved to be the precursors of fresh abscesses, as many as six of which were opened within as many weeks. Although the drainage was good, the inflammation extended and finally involved a large part of the left side of the neck. The general health was failing. A deep sinus in the neck was then explored, and the tissue in the neighborhood was found to present an appearance of soft cancer. Then for the first time it was suspected that the case was one which had degenerated into malignant disease. His suspicions were confirmed on microscopic examination of a part of the cancerous tissue. The man died two or three days ago. It seemed evidently a case in which a sore, non-malignant in the beginning, changed its character, and became undoubtedly cancerous in the end.

Dr. Post remarked that he had a case last year in which cancer developed at the seat of an old gun-shot wound received at the battle of Bull Run. Microscopical examination showed that it was a cancerous growth.

The President had related a case to the society on a former occasion to the following effect: A physician brought a young married woman, twenty-five years of age, to the Woman's Hospital, with the evidence of abscess in the cellular tissue about...
the uterns. The abscess was found to be of about the size of a
duck’s egg; the patient was suffering a good deal of pain from
cellulitis excited by some application made to the cervix uteri
cervical catarrh, which had produced sterility. About an
ounce or an ounce and a half of lanced pus was found in the
abscess. The patient was kept in bed three or four weeks, and
was then suddenly taken with profuse hemorrhage, which was
found to come, not from the uterns, but from the seat of the
old abscess. Careful physical and microscopical examination
showed that cancer had developed, of which the patient died
within about a year.

In another case, a healthy woman, on leaving the house,
nipped on the icy steps and fell upon her buttocks, confining
her to the bed a week or ten days. Shortly afterward hemorrhage
occurred from the uterns, and six weeks from the date of the
fall well-marked cancer of the womb was discovered. The
malignant disease had probably existed before the patient fell,
but as symptoms did not manifest themselves until afterward, it
was natural that the patient should attribute them to this acci-
dent.

Tait’s Operation for the Removal of the Ovaries.—
Some remarks upon the operation first performed some years
ago by Hegar, of Germany, for removal of the ovaries in cases of
large fibrous tumors of the uterus for the purpose of dimin-
ishing their nutritive supply and checking their growth. A
paper was read upon the subject by Dr. Knowsley Thornton, at
the last meeting of the American Gynecological Society. The
operation had been represented to be a very simple one, easy to
perform, and comparatively without danger. The President had
performed it in three cases, had attempted it in a fourth, and it
seemed to him beyond question an exceedingly difficult opera-
tion, very much more dangerous than ovariotomy even in cases of
large tumors, and in a large number of cases it would proba-
bly prove fatal. His first two patients were operated upon in
October and November last. The tumors were large, but after
the removal of the ovaries they steadily diminished in size.
The patient made a good recovery. The third case was opera-
ted upon a month ago; it was found to be almost impossible to
remove the ovaries, they were bound down so tightly by adhe-
sions and surrounded by masses of lymph due to repeated at-
tacks of peritonitis. This patient died of septic peritonitis.
The last case was operated upon to-day. The tumor was of
the size of a large coconut. The patient was twenty-eight
to thirty years of age, had been in the hospital three months,
suffered extremely at the menstrual epochs, and lost much
blood, although the tumor was not situated in the uterine
cavity itself. Her sufferings were so great that she clam-
ored for an operation. To-day an incision was made along the
linea alba, the hand was passed down, and the left ovary
was found so strongly fixed to the pelvic tissues that it could
not be removed except by tearing it loose from its attachments.
The right ovary was found to be bound down in a similar man-
ner, and in a state of cystic degeneration. Remembering his
experience in the other cases operated upon, he felt that to re-
move the ovaries under the circumstances was an unwarrantable
procedure, and they were left in position. Moreover, although
the patient suffered a great deal, life was not really in danger.
He mentioned the case simply to express his opinion that the
operation was an extremely hazardous one—much more dan-
gerous than the operation for the removal of large ovarian tumors.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held March 8, 1883, the President,
Dr. James Tyson, in the chair.

Cancer involving the Stomach, Liver, Pancreas, Rect-
um, and Lungs.—Dr. Cuy Herdard exhibited a series of spec-
imens obtained from recent cases at the Episcopal Hospital.

Case I.—Carl W., aged forty-four, was admitted October 23,
1882. He had never been ill before, and his symptoms had been
developed during the two weeks previous to admission. His
bowels were regular, he had had no vomiting, but had pain at the
lower margin of the left ribs, with cough and friction
sounds. Caeoxin was marked. The abdomen was soft; a tu-
mor was felt in the left hypochondriac region. The spleen was
distinctly felt, and enlarged.

The tumor increased in size, became more tender, and pain
was at times very severe. The patient’s appetite was gone, and
emaciation was extreme. Twenty-six days after admission
death occurred.

At the autopsy, fluid was found in the pleural, pericardial,
and abdominal cavities. There were old purulent adhesions.
The roots of the lungs, the base of the left lung adjacent to the
diaphragm, and the pleura beneath the ninth and tenth ribs, were
found to be the seat of cancerous deposit. The bronchial and
thyroid glands were very much hypertrophied, but not can-
cerous.

The cardiac extremity of the stomach was the seat of an ex-
tensive cancer, but the cardiac orifice was not involved, and the
mucous membrane not destroyed. The pyloric end was intact.
The pancreas was the seat of cancerous growth. The liver was
of a dark, mottled color, and showed numerous metastatic
growths in an early stage of development; its weight was 5
pounds 9 ounces. The spleen was greatly enlarged, and the seat
of small secondary deposits. Kidneys normal.

Microscopic sections of the thyroid gland showed simple hy-
pertrophy; sections of the metastatic growth in the liver showed
sclerous cancer.

Case II.—James S., aged forty, admitted September 28, 1882.
During two months previous to admission he had lost forty
pounds of flesh, his skin had become very sallow, and vomit-
ing, which at first was occasional, finally occurred after every meal.
A tumor was distinctly felt on the left side above the umbilicus;
it moved with respiration, and was painful on pressure. Albu-
min was present in the urine. The patient’s mother had died
of cancer of the stomach.

After admission, the tumor increased in size, the patient
 grew weaker, vomiting frequently and passing clay-colored
 stools. Death occurred on the thirty-eighth day after ad-
 mission.

At the autopsy, the heart, lungs, kidneys, and spleen were
found to be in a normal condition; the stomach was very much
dilated, and contained undigested food. A cancer was found at
the pyloric extremity. The walls of the pylorus were very
much thickened, and its orifice admitted the thumb with dif-
culty.

The liver was detached, and found to be the seat of four
large bosses of secondary cancer. Its weight was 8 pounds 14
ounces. The gall duct was unobstructed.

A microscopic section of the growth in the stomach showed
sclerous cancer.

Case III. Cancer of the Stomach; Gastro colic Fistula.
—C. W., aged sixty-six, was admitted June 13, 1883. His health
had been good until four months previously, when he vomited
some dark, bloody matter. Pain was occasional, and occurred
after eating. Vomiting had occurred once. Jaundice began
three weeks before admission; the skin was dry, and the body
not much emaciated. Stools regular, but clay-colored. The liver
was slightly enlarged. Distinct nodular masses, slightly painful
on pressure, could be felt in the epigastric and umbilical regions.
The inguinal glands were slightly enlarged; the axillary glands
remained normal. There was no cough. A faint, low systolic murmur was heard at the aortic cartilages. The urine was dark-yellow, sp. gr. 1.030, and contained no albumin. Vomiting, emaciation, and jaundice progressed, the tumors increased in size, and death occurred two months after admission.

At the autopsy, a cancer was found at the pylorus. A fistulous opening, large enough to admit the forefinger, was found to exist between the stomach and transverse colon, which were infiltrated by the cancerous deposit and adherent to each other. The caliber of the colon was small. The mucous membrane of the stomach at the seat of disease was ulcerated and ragged. There was no dilatation or hypertrophy of the walls of the organ. The gall-bladder was distended, and both the pancreatic and common bile duct were obliterated. Heart, kidneys, and other organs showed nothing very unusual. The mesenteric glands were slightly enlarged. The spleen was small, and its hilus the seat of a hard, calcareous plate; the organ was displaced, lying close against the diaphragm, some distance from the chest-wall, accounting for the perfect resonance which had been noted in the splenic region.

Case IV. Rectal Cancer; Colotomy.—John M., aged seventy-one, was admitted to the hospital October 26, 1882. He had always been healthy until three months previously, when the movements of his bowels became irregular.

The patient suffered from diarrhea. His urine was albuminous, and contained hyaline casts. He had hydrocele. He denied specific history. Exploration of the rectum revealed a malignant stricture an inch and a half from the anus.

On account of the patient's age, operative measures were not contemplated until the passages became very difficult and hic-cough and stercoraceous vomiting demanded relief. This was temporarily afforded by the operation of lateral lithotomy, which was performed by Dr. John H. Packard. Death ensued twenty-four hours later.

At the autopsy, the wound was found in good condition; the descending colon was opened about three inches from the point of its bending downward. An enormous cancer was found involving the rectum and posterior wall of the bladder, and nearly filling the true pelvis. All the other viscerae were in good condition. Microscopic sections showed the cancer to be sarcomatous.

Case V. Cancer of the Rectum; Secondary Cancer of the Liver.—Christian H. was admitted July 6, 1882. He was emaciated, weak, and emetic. He stated that for twenty-seven years he had been perfectly well, but that two months previously he had noticed loss of flesh, and about the same time discovered at the anus a growth which was small, but which gave him a great deal of trouble at stool.

Two weeks later he noticed that his feet and legs had become swollen, but it was not till his admission to the hospital that he became aware that there was anything the matter with his abdomen. The patient's father probably died of cancer of the stomach.

The anal growth was excised, and proved to be an adenoid type of malignant disease. Vomiting, dyspepsia, and sallowness of the skin increased until his death, five weeks after admission. The autopsy showed that the liver and rectum were the only structures seriously diseased. The liver was enormously enlarged, and filled the whole upper portion of the abdominal cavity. It was slightly adherent to the diaphragm and adjacent viscera, and was studded with cancer nodules, varying in size from that of a filbert to that of an egg, often coalescing and pretty equally distributed over the surface. The whitish color of these nodules was in strong contrast with the dark color of the liver, giving it a variegated appearance. Its weight was 10 pounds 4½ ounces. The walls of the rectum, six inches from the anus, were infiltrated with the new growth. This was the primary seat of disease. The secondary growth was very rapid, almost entirely painless in itself, and disturbing the patient only by mechanical irritation of the stomach, and the production of edema and ascites by interference with the circulation. Jaundice did not occur.

Microscopic sections of the anal growth revealed an adenoid growth resembling an aggregation of Lieberkühn's crypts. It was an example of an early involvement of the part. The growth higher up in the rectum was more advanced, and illustrated the ependymoid form of the disease. A section from the metastatic deposit in the liver showed a stroma of fibrous tissue, with alveoli lined by epithelial cells, the peripheral cells retaining their columnar shape. It was an example of the reproduction in the liver of the same follicles found in the primary disease of the rectum.

Ossification at the Aortic Orifice.—A unique specimen was exhibited by Dr. J. T. Esksrider. It was sent him from a distance, and consisted of about one inch of the cardiac end of the thoracic aorta, the aortic semi-lunar valves, and the immediate portion of the heart. The specimen was removed from a man who, aged about seventy, had suffered a number of years from severe heart disease. The walls of the large arteries were thickened, rigid, and contained numerous deposits of inorganic matter. The left ventricle was enormously enlarged. He was unable to obtain any information with regard to the condition of the cardiac valves other than those of the aortic orifice.

Description of the Specimen.—The aorta, where it surrounded the valves, for about half an inch in extent, was a hard, unyielding substance of fibrous tissue and calcified and ossified matter. The valves in several places were about one fourth of an inch thick, and seemed to have been almost entirely transformed in to bone-like material. They were rigid and inmovable, and had almost completely cut off all communication between the heart and aorta. One of the leaflets, about three fourths of an inch in all directions, with its vegetations, stretched across the aorta, lay against, and was apparently adherent to, the other segments of the valves, the latter being curled upon themselves. The central portion of the aorta was entirely occluded, and only two small openings, through which the blood could have escaped from the left ventricle, were seen between the valvar leaflets near their peripheral attachments. The larger of these holes admitted a flattened probe three mm. wide by one thick; the smaller was about two thirds as large. Three other smaller orifices had existed, but these were obliterated before death by a thin, fibrous, transparent membrane, which was still seen. The valves on the cardiac side were tolerably smooth, but on the aortic side they were very rough, one of the leaflets supporting a vegetation ten mm. long. One of the segments of the valves was adherent to the inner coat of the aorta for about half an inch in extent, the free end of the valve being folded upon itself and pointing toward the nearly closed aortic orifice. After macerating the specimen in water for forty-eight hours, the diseased valves still remained inflexible.

Dr. Forand, Dunn, Griffith, and Edwards reported having similar, or nearly similar cases.

Dr. Ttson and Nachebe called in question the correctness of calling the disease ossification of the valves, as it was in reality a calcification.

Dr. Shakespeare concurred in this view, and thought that ossification rarely, if ever, occurred in this situation.

Dr. Esksrider said that Hayden ("Diseases of the Heart and Aorta," vol. ii, p. 839) referred to bony deposits in the aorta and its valves as follows: Sir Dominic Corrigan exhibited before the Pathological Society of Dublin (see Proceedings, vol. ii, New Series, February, 1864) the heart of a young woman in which the root of the aorta had undergone complete osteoid
transformation; it was likewise greatly dilated, and the aortic valves had been rendered thereby inadequate. During the patient's last illness, a systolic murmur of metallic quality, appropriately designated a "trumpet-bruit," was audible at the base, and in the ascending aorta and carotid arteries; there was likewise a soft diastolic murmur. He regards a "trumpet-bruit" as absolutely diagnostic of bony deposit in the aorta, either in the form of a "rim of bone," or a "projection or tongue of bone." In the same paragraph Corrigan refers to Dr. Bank's specimen of a "tongue of bone" projecting into the aortic orifice.

Reports of the Committee on Morris Growth.—"A microscopic examination of a section made from the growth removed from the uterus and presented by Dr. Parsons, December 28, 1882, shows it to be adenomatous in structure, consisting of small cavities or spaces lined with cells, which cavities are separated from one another by fibrous connective tissue." A section of the lymph gland, presented by Dr. Parsons December 28, 1882, shows that its normal structure is metamorphosed into that of a carcinomatous nature, consisting of an alveolar fibrous stroma, having the spaces filled with cells of an epitheliomatous type." Report on Dr. Eckman's specimen of brain, lung, liver, spleen, kidney, and bladder troubles, presented November 9, 1882. A section made from one of the nodules of the liver, presented by Dr. Eckman, examined microscopically, shows it to be a new formation, consisting of epithelial cells placed in alveolar spaces, the tissue forming the alveolar walls being fibrous connective tissue. The cells in the spaces at the periphery of the groups, and lying next to the alveolar walls, have a columnar shape, and are quite regularly arranged, while those of the center are flat or squamous epithelial cells. The neoplasms are cylindrical-celled epithelium. The post-mortem changes undergone by the brain were such as to prevent any satisfactory histological examination being made.

"A section of the growth, presented by Dr. Nancerec, January 11, 1883, for Dr. SELTZER, on microscopical examination, shows it to consist of an external covering formed of the histological elements and arrangement as found in the skin; the papillae were in places much atrophied and flattened, also in some parts elongated. There were no hair follicles, sweat, or sebaceous glands in the section. Below the papillae were seen fibrous tissue, at some points in an active state of proliferation, and numerous blood-vessels. The growth is a fibrous polypus."

A Tumor composed of Millary Tubercles of the Sereutaneous Adipose Tissue connected with one of the anterior Cutaneous Branches of the Lumbar Nervees. This was exhibited by Dr. Nancerec, who said the patient from whom this truly unique tumor was removed was a young girl of eighteen years of age, who, for four years past, had had occasional coughs, with, at times, some bloody expectoration, but was able to attend to her occupation of housework. Her family history was not characteristic in any way. About one year since she thought that she "strained herself," since when she has been subject to severe attacks of abdominal pain, which extend to various portions of her body. She was admitted to the Female Medical Wards of the Episcopal Hospital last fall, where dulness on percussion and harsh respiration at the apex of one of the lungs were detected. During December, 1882, the pains increased, and the right thigh became flexed upon the abdomen. A small, exquisitely sensitive, nodulated tumor was now detected just to the outer side of the right rectus abdominis. Dr. Morris J. Lewis, by whose kindness I am enabled to present this specimen, then asked me to see the case with him. Under ether I found a nodulated mass, beneath but attached to the skin, and freely movable upon the deeper parts. I then thought that the growth was one of the ordinary so-called neuromata—i.e., usually fibrous growths in connection with some nerve, and that the pains were

OBSTETRICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held April 5, 1883, the President, R. A. CLEEMANN, M.D., in the chair.

Calcareaous Particles passed per Vaginam. — The specimens were shown by Dr. W. Goodell. The previous history had been that of menorrhagia, and multiple fibroids were found in the womb. One of these fibroids had evidently taken on calcareous degeneration, and had subsequently broken down, and discharged these fragments into the uterine cavity. He stated that these particles were not true bone, but merely the product of a disorderly deposit of lime, which possessed none of the osseous elements, not even cartilage corpuscles. This calcareous degeneration tended to excite the disease by breaking off the vascular filaments of attachment and lessening the nutrition of the fibroid. In one instance, the specimen of which was now in the Museum of the University of Pennsylvania, he had seen three fibroids wholly converted into stone. These stones were, however, very light, and not like those of the bladder. It was the expulsion per vaginam of these uterine calculi which had greatly puzzled the older anatomists.

Stone in the Female Bladder associated with Fistulous Connection with the Bowels.—Dr. Goodell also exhibited two calculi, and related the following histories of two cases: The first case was that of a patient of Dr. C. A. McCull, who sent her to him in October, 1881. For the preceding four years she had suffered very much from vesical tenesmus. She frequently broke wind per urethram, and often passed through the same
channel the seeds of raspberries, of tomatoes, and of pears. A year before Dr. Goodell saw her she had voided a great deal of her urine per rectum for several weeks. Dr. Goodell detected two stones in the bladder and removed them. At once all the symptoms of fistulous connection between the bladder and the bowels disappeared, and the patient got well. This rapid recovery led him to think that there had not existed any fecal fistula, but that the vesical tenesmus was so great as to cause a rectal tenesmus which was masked by the former, and that the seeds and urine were voided per rectum unconsciously by the woman when attempting to empty the bladder. But he had been led to change his views by the following case which he had seen with Dr. William Corson, and which Dr. Ellwood Corson was kind enough to report for him. Mislaid by the first case, Dr. Goodell was not at first disposed to admit the existence of a fecal fistula, but, from the subsequent history of the case, there could be no doubt of it. In this case he believed that a pelvic abscess had burst into the bladder and also into the rectum or small intestines, which had established the communication between the two viscer. Like the first case, as soon as the calculus was removed, the fistulous tract closed and the patient got well. "Mrs. R., American, aged fifty years, the mother of five children. For three or four years prior to November, 1881, she was troubled occasionally by the passage of small calculi, but her health was reasonably good, with the exception of backache and an almost constant pain in the right iliac region. She often expressed her belief that there was something growing in the right side. There was no tumefaction in that region, and her opinion was based on the pain and distress she felt. She never applied to her physician for relief of this suffering. She was also troubled with constipation. In November, 1881, she made a visit to the country and took a long walk. On her return home she had a constant desire to urinate, and she then noticed, for the first time, that her urine had an unnatural color and a very unpleasant odor. The quantity passed was not excessive. This condition continued for five or six days, when there occurred a sudden gush from the bladder of a very offensive mixture of pus and urine, accompanied by great pain and straining. Her pain and distress became so great, and was so augmented by being on her feet, that she was compelled to remain in bed. After the free discharge occurred the pain in the right iliac region ceased, and she has never had any return of it. As she was troubled with constipation, she was directed to eat stewed prunes, and she soon noticed that the prune-skins came from the bladder, as did other articles of food, along with the urine. Every day she was troubled with the escape of gas through the urethra, and this gave her as much pain as the passage of solid matter. She says that she occasionally passed urine through the rectum. She became greatly emaciated, and was but partially relieved of her suffering by the constant use of morphia. Until January 20, 1882, she was under the care of homeopathic physicians. On that date Dr. William Corson was called to the case. February 10th Dr. William Goodell saw her, and diagnosticated stone in the bladder. February 20th she was etherized and the urethra dilated, and a digital examination proved the existence of a calculus about three fourths of an inch in diameter, attached to the fundus of the bladder. This was removed by Dr. Ellwood Corson. In attempting to dislodge the calculus, it crumbled on slight pressure with the extracting forceps, and proved to be a mass of fecal matter with a calcareous crust but slightly thicker than an egg-shell. While she was under the influence of the anaesthetic, an attempt was made to wash out the bladder, but after injecting ½ xij of water, and finding that it escaped into the interior of the body and did not remain in the bladder, the washing-out process was discontinued. After she regained partial consciousness and made a strong straining effort, the injection came away through the urethra. As there were some doubts expressed as to the possibility of there being an opening from the bowels to the bladder, she was induced to eat a few stewed figs, and the seeds were seen to come from the urethra; on another occasion ½ xij of carmine-colored water was injected into the rectum, and was immediately drawn from the bladder by means of a catheter. After the removal of the calculus it was thought proper to keep the bladder washed out daily with warm injections, and to regulate the bowels with mild aperients; but, after persisting in this course of treatment for four days, it was abandoned, as it ceased her great discomfort and did not improve her condition. Afterward she was allowed to eat such food as the system craved, care being taken to select such articles as would not leave an irritating residuum. She rapidly improved, and since April, 1882, has had no trouble with her bladder. If she eats seeded fruits, or drinks lemonade, she has some irritation in passing urine. That there was a fistulous opening from the bladder to the rectum there can be no doubt; and when we take into consideration the fact of an abscess forming somewhere in the right iliac region and opening into the bladder, and that the food passed from the bladder in a semi-digested state and the absence of a fecal odor, there is a strong probability that there was also an opening from the small intestines into the bladder."

Dr. J. C. Montus had seen two cases of pelvic abscess bursting into the bladder. One case was in the person of a night-nurse at the Episcopal Hospital. A tumor in the lower part of the abdomen first attracted attention. The uterus was drawn up out of reach of the finger when making a vaginal examination; an inflammatory mass could be felt between the uterus and bladder; every half-hour a mixture of urine and pus was voided per urethram. If a catheter was passed into the bladder and turned to the right, urine escaped through it, but, if it was passed to the left, nearly pure pus passed through it. Examination with the sound showed a large fibroid in the anterior wall of the uterus. This tumor having undergone parenchymatous degeneration, and a fistulous opening being established into the bladder, the pus escaped through the bladder. A galvanic stenopassive five and a half inches long was introduced into the uterus, and was finally successful in effecting its reduction to the normal size. This woman died of fibroid phlebitis, and at the post-mortem examination the uterus was found but slightly enlarged, and the fistula into the bladder was not seen, but a communication from the small intestine into the bladder was discovered.

Dr. W. N. Paresi had seen one case of fistulous communication between the bladder, vagina, and small intestine, resulting from an attempted abortion and consequent cellulitis. After long-continued pelvic symptoms, food commenced to pass through the bladder and the anterior and upper portion of the vagina. Water injected into the vagina passed into the bladder, but a sound, could not be made to follow it. The food which passed through the fistula was incompletely digested. Porro's Operation.—Dr. Elliott Richardson read a report of the post-mortem examination of the body of Lina Earl. This woman was operated upon September 22, 1880, for removal of a living child from the uterus by Caesarean section as modified by Porro and Müller. A report of the case was published in the "American Journal of the Medical Sciences" for January, 1881. The immediate results of the operation were in every way favorable. The child was living, and the mother made a speedy recovery. She died in New York, on February 24, 1885, two years and five months after the operation. She had been for two years previous to her death at times an invalid, and was under my care occasionally for the treatment of attacks of acute rheumatism, anemia, etc., to which her life of hardships and
exposure as an exhibiting curiosity rendered her peculiarly lia-
ble. The more recent symptoms which appeared during the last illness I did not witness, but learned were attributable to
defective action of the kidneys. At the post-mortem examina-
tion, made about 9 P.M. on February 24th, ten hours after
death, there were present Dr. Satterthwaite and Dr. Hegeman,
of New York, and myself.

Inspection of the body showed the long bones of the ex-
tremities to be deformed as in rachitis—deformities which had
not been so apparent during life. General anaesthesia was present.
On the surface of the abdomen a cicatrix was observed extending
from a point about one inch and a half above the umbilicus to
within about three fourths of an inch of the symphysis pubis.
The cicatrix was the remains of the abdominal incision made
at the time of the operation for her delivery, and occupied the
linea alba, directly in the median line, except that at the um-
bilicus it was deflected to the left. Nearly the whole of that
portion of the cicatrix extending between the symphysis pubis
and the umbilicus was the site of a large hernia, which, how-
ever, did not extend into the latter. This hernia he had seen
during the patient's life. It began to appear about six months
after the operation, and received no treatment whatever until
by its size it became inconvenient; then a bandage or truss was
applied, and this she wore constantly until her death. The pro-
duction and enlargement of the hernia had been greatly fa-
avored by the woman's course of life as an exhibitor of herself
and child, for the latter she lifted up and held in her arms many
times a day in order to display it to her visitors, even after it
had become much too heavy for her to carry.

The body was opened by a long incision from the top of the
sternum to the symphysis pubis. This incision was deflected to
one side opposite the cicatrix of the old abdominal wound, in
order that the relations of this to the abdominal contents might
be more closely observed. The body, as before stated, was ana-
sarcous throughout; some clear serous fluid was found in the
peritoneal cavity, and a good deal in the cavities of the pleural
and the pericardial sac. Dr. Richardson regretted that he had
no data of the microscopic appearance of any internal organ
or tissue to give. Only the gross impressions which could be de-
tected by the unaided eye in a hasty examination could be given.
The heart was not opened, but the left ventricle appeared ab-
normally large. The lungs were edematous, and pneumonia of
the right side was observed. The spleen was enlarged. The liver
presented an appearance of fibrous or "hob-nail" degener-
ation. The kidneys showed unmistakably the existence of
Bright's disease. The abdominal and pelvic cavities gave no evi-
dence of any peritoneal or cellular disease. The hernia was
found to be covered by peritoneum and skin, the remaining
structure having partly to admit the protrusion of the intesti-
nes and peritoneal covering. No adhesions between the cicat-
rix and subjacent structures could be detected except at the
lower angle of the wound. It was at this point that the stump
of the uterus had been fixed in a manner similar to the disposal
of the pedicle in ovariotomy. A fibrous band was found ex-
tending from a depression in the abdominal wall at this point to
a body consisting of the remains of the uterus.

Dr. Satterthwaite, who examined these specimens, had writ-
ten him that this body, which occupied nearly the normal pos-
tion of the cervix uteri except that it was displaced somewhat
anteri0rly, presented the following characteristics: "The ex-

treme length of the stump was 4 75 cms. (1 87 inch); vertical

thickness 2 25 cms. (1 inch); its breadth 1 5 cms. (½ inch). On

trying to pass a uterine probe into the os externum, it was

found to enter with difficulty, though the cervical canal was

capable of admitting a No. 19 (English) sound. The mucous

membrane was coated with a deposit of white, thick, gelatinous

material, and was intact for a distance of 3-5 cms. (1 5 inch.)

No naked-eye evidences of cicatrical tissue were made out at

the amputated extremity of the neck."

Examination of the pelvis in situ had been of much inter-

est. Measurement of the superior strait gave for the conjugate
diameter 2 inches exactly; transverse diameter, 4½ inches ex-

actly; oblique diameter, 4¾ inches exactly. The pelvis was a

rachitic one, although the pavilion did not present the wide-

spreading alae or the diverging anterior-superior spinous pro-
cesses of the ilia which were the usual deformities of rachitis in

this part of the pelvis. The true pelvis, however, presented

highly characteristic deformities. The sacrum was at its upper

part dislocated and pressed downward and forward into the

pelvic cavity, while the lower extremity, being held by ligamen-
tous bands to the ischia and pubes, caused a sharp bending

forward of the last three vertebrae of the sacrum. This deforma-

ity implied abnormal softness and pliability of the bone at a time

when the individual was of sufficient age to either stand or sit

erect, so that it alone was conclusive evidence of rachitis having

existed. The normal curvature of the pubes bones was nearly

lost, so that they receded from the symphysis in nearly straight

lines backward and outward to join the ischia and ilia, the
two pubes bones, when viewed from above, forming an abnormal

angle at the symphysis. The shape of the superior strait was

therefore obtusely corolate, deeply indented at its base by the

preomontary of the sacrum projecting far into it. He was much

surprised at the evidences of rachitis, which became more and

more conclusive as the examination proceeded, since the his-
tory of the patient formerly given was that of excellent health

from birth to the time of the operation in 1880, and it was

said by the woman, and those who had known her best in early

life, that she was in her figure an almost exact counterpart of

her father. These supposed facts had led him to believe that

her shape was due to arrested growth and not to rachitis.

It would be of interest to know that the child of this woman

was now living, that he was well developed, and presented no

deformity or any symptom of rachitis. He was of fair size

for his age.

In closing, he would draw the following conclusions from the

examination:

1. That the deformity of the pelvis and extremities was due to

rachitis.

2. That the operation had nothing to do with the patient's

death.

3. That the operation caused the patient no inconvenience

except from the hernia, which would either not have become

developed, or, at most, would have been small, had it not been

for the exposure of the woman to unusual strain and her total

neglect to resort to any treatment until the hernia became large.

4. That success, in so far as the woman was concerned, would

have been possible, and even probable, with diameters so large,

if embryotomy had been resorted to in this case; but the op-

eration would still have been dangerous, and the child would

necessarily have perished.

Dr. R. P. Harris remarked that, of five Porro operations

in this country, four have proved fatal. This was the first success-

ful operation in which a post-mortem examination had been ob-

tained after entire recovery.

In reply to Dr. A. H. Smith, Dr. Richardson stated that no

trace of a fistulous opening between the stump of the uterus

and the abdominal wall existed at the time of death.

Supporting Cyst of the Broad Ligament, which had

perforated the Bladdet.—Dr. B. F. Bahr read the history of

the case, and exhibited the specimens removed by laparotomy.

The characteristic pustis were chillls, exhaustion, anorexia, ten-

derness throughout the lower abdomen, and a small, painful tu-
mor in the left iliac region, with great irritability of the bladder. Pulse 120, temperature 100° to 102° F. The tumor extended down between the bladder and uterus, and the latter was retroverted. Douglas's cul-de-sac was occupied by a thin-walled fluctuating cyst, about the size of a large orange. The uterus could be moved slightly from side to side. The anterior tumor rested on the bladder, and was adherent to it. The history showed a slowly growing cyst with purulent contents, commencing about three years before, when the first chills and a mild septicaemic fever had occurred; gradual emaciation had been progressive since that time. Typhannite in connexion of the tumor gave evidence of decomposition, with evolution of gases. When the catheter was passed before operating, several ounces of very fetid pus flowed through it, showing a spontaneous rupture of the cyst into the bladder. The cyst was found adherent to the abdominal wall and to the bladder, but not to the intestines or uterus. The cyst was aspirated and removed by laparotomy. The pedicle, consisting of broad ligament and Fallopian tube, to which the left ovary was adherent, was transected and ligated. The cyst in Douglas's pouch arose from the opposite broad ligament; it had formed no adhesions, and was removed without evacuation of its contents. The ovary and Fallopian tube were healthy, and were not removed. The aperture in the bladder through which the contents of the cyst had escaped was valvular, and was closed by the compression furnished by the external dressings. The patient died from exhaustion soon after the close of the operation. Dr. Baer introduced cases from W. L. Atlee, Peaslee, Keith, George F. French, and Goodell, to prove the correctness of the principles upon which he operated.

Dr. W. H. Pansn thought Dr. Baer's rules safe and sound; he had removed a suppuring cyst with anterior adhesions. An experienced operator, who was present, recommended delay; but, feeling sure of the correctness of his own principles, he removed the cyst and the patient recovered.

In another case, in which a fistulous opening discharging pus existed, suppurative peritonitis was diagnosed, but, after death from septicaemia, a post-mortem examination revealed a suppurating cyst of the ovary.

W. H. H. Guthens, M. D., Secretary.
though well marked discolorations they cause, they may be rendered ditubate by being so modified that they will form an emulation with water, thus: B Plics mineralis (vel oel ealini), 3 ij; spiritus rectificati, 3 sj. Cola et ad liquores ammoniacum fort., 3/ij; gley erina (Price), 3 vj; aqua destillata ad 3 xij. M. Sig. Sponge the parts two or three times daily. Fix a liquid may also be rendered miscible in all proportions with water by the addition of Lanicaria saccharina (sea salt). Carabolic acid is of less value in emesis than the tarry preparations, though it may succeed when the latter fail. The astringent solution, in which form carabolic acid is generally used, is colorless, and its odor, though pronounced, is less disagreeable than that of some of the tars. It removes fixed exhalations, allays itching, and sometimes quickly heals ulcerations and excoriation. The strength of the solution should depend on the chronicity of the disease. Mercury is sometimes of service in emesis, especially when the itching has moderated and the exudation and induration have disappeared. Unless there is a syphilitic taint, it is, however; inferior to tarry preparations. Any of the official ointments may be used, or the proportion of mercury in them may be increased or diminished according to a more stimulating or less irritating ointment is indicated. Cyanide of potas sium, carabolic acid, or camphor may be added if it is itching. A lotion may be made by dissolving bichloride of mercury, one to four grains, in a little alcohol, and adding an ounce of rose or lavender water. Dilute hydrocyanic acid may be combined with this if necessary. Care must be taken in giving any preparation of mercury to avoid salivation. Sulphur, except as it kills parasites, is of doubtful utility. Emollient ointments are best applied spread upon soft cloths; stimulating ointments should usually be melted on the finger-end and rubbed thoroughly into the part. None should remain undissolved on the surface, which should simply appear as though recently moistened. Great care should be exercised to prevent the use of renal ointments. The application of such tends to aggravate the disease rather than to relieve it. Astringents, though of some use in emesis, are inferior to other remedies.

How to Bring Up Infants.—Mr. Edmund Owen, F. R. C. S., of London, gives the following instructions to out patients.

What Food to give.—Mother’s milk is the proper food for babies, and until they are three or four months old they should have nothing else. But if that can not be got, or be not sufficient, cow’s milk fresh two or three times a day, and from the same cow, and not sealed, is the next best food; but it must be freely diluted, as it is much too “strong.” The bottle should be filled with a mixture of cow’s milk and warm water, in which a lump of white sugar and a very small pinch of salt have been dissolved. For the first few months there should be more water than milk—perhaps twice as much water as milk —and, as the baby thrives, the proportion of milk may be gradually increased. No other food should be given before the sixth month; baked flour, arrowroot, and oatmeal can not be digested, so they cause sickness and diarrhea. When to give it.—For the first month a baby should be fed every two hours, and, by gradually increasing the interval, he is in time fed every three and, eventually, every four hours. He should not be fed because he cries; very likely he is in pain because his stomach is overloaded. When he is sick after his milk he should be fed for a less time and at shorter intervals, and, if the bottle is being used, a larger proportion of water must be tried; and, if he is a fast sleeper, he should be waked up for his regular meals, and, never allowed to over-feed. A tablespoonful of lime-water may be added to each bottleful of food, and especially so in summer.

How to give it.—The best kind of feeding-bottle is the old-fashioned, long, straight one, with a short India-rubber teat and with tube at all. The very worst kind is that with the long India-rubber tube. There should be two bottles—one for day and one for night; after being used, the bottle should be thoroughly washed in hot water, in which a little soda has been dissolved, and should then be well rinsed in cold water. Till next wanted it should be kept in a basin of clean cold water. When six months old the baby may be allowed, in addition to milk, boiled bread and milk, oatmeal, Bobb’s biscuits or Chapple’s wheat flour.

Wearing.—As a rule, when the baby is about nine months old the mother should begin to wean him by giving him less of the breast or bottle, and more of the cow’s milk and of the foods just mentioned, and, in addition, a little beef-tea or meat-broth and soaked bread. At a year old the child must be entirely weaned, and soon he must have daily a little under-cooked meat pounded up into a pulp, and to which a little gravy and salt are added; some potato finely mashed and curled with gravy; an egg; or a little milk-pudding. On no account should he be allowed any wine, beer, tea, or coffee, though he may have cocoa and milk. He should be given his meals regularly, and he should not be allowed to “pick” at bread and butter, cakes, and sweet stuff in the intervals. Children flourish best on fresh foods. The worst nourished patients that I see at the hospital for sick children are those reared on Swiss milk and various patent foods. Rule.—Do not give a baby food or physic that is advertised.

Clothing.—Babies and little children must be kept always warm. They can not be “hardened” by scanty clothing or cold baths. Their necks, thighs, legs, and arms need to be covered as well as their chests and bodies; they should wear long sleeves and stockings, and, when old enough, cotton or flannel drawers.

Fresh Air.—Children should be taken out of doors every day that the weather is fine. If they are sent out in a perambulator, care must be taken that the feet and legs are warm to start with, and that they are so well covered throughout the ride that they are warm in the return home. Every day, unless a bitter wind is blowing, or it is foggy, the children should be opened for a while, for fresh air is as necessary for children as fresh food.

Sleeping.—At night if a child perspires freely or kicks off the bed-clothes, he should wear a flannel bed-gown long enough to be tied below his feet, and the bed-clothes must be securely tucked in. He should not be rocked or patted to make him sleep; sleep should come naturally, and, like the food, at regular intervals.

Bathing.—Morning and night he should be washed all over in warm water, but should not be exposed long enough to feel chilly afterward. A handful of sea-salt, thoroughly dissolved, may be added to the bath. Except in the very warmest weather no little child should be put in a cold bath.

Infant Mortality and the “Baby’s Bottle.”—Dr. R. Dear Fox, Manchester, writing on the subject of infant mortality, speaks of his experience as an old resident medical officer at the workhouse, and as surgeon to a children’s hospital, which has taught him to regard as a very fruitful source of milk-poisoning the decomposition from the vessel which is used to feed the child. He feels sure all of his confrères who have to treat the children of the poor will agree with him that ninety-nine per cent. of the bottles out of which children are fed are offensive from the odor of the decomposed milk, which adheres about the cork, tube, or tent through which the children suck, and in the bottle itself rings of adherent putrefying milk marks, as tide lines, how much the child has taken at a meal. He adds: “The use and abuse of the ‘baby’s bottle’ would be a fit subject for inquiry by our local sanitary association; and, assisted by its lady members, might not devote some of its energy to a teaching crusade among the women in the poorer districts of the town?”—Med. Times and Gazette.

Bathers’ Cramp.—Some recent bathing fatalities have again drawn attention to the important subject of bathers’ cramp. If the nature and causes of this dangerous affection were more generally known, it is probable that many deaths from drowning in the bathing season might be prevented. Cramp is a painful and tonic muscular spasm. It may occur in any part of the body, but it is especially apt to occur in the lower extremities, and, in its milier forms, it is limited to a single muscle. Pain is severe, and the contracted muscles are hard and exquisitely tender. In a few minutes the spasm and pain cease, leaving a local sensation of fatigue and soreness. When cramp affects only one extremity, no swimmer or bather, endowed with average presence of mind, need drown; but when cramp seizes the whole of the voluntary muscular system, as it probably does in the worst cases, nothing, in the absence of prompt and efficient extrication, can save the individual from drowning. Although the intimate nature of muscular cramps and the precise mode in which they are estab-
fished are still unknown, experience has furnished us with sufficient
data on the subject to enable us to recognize the chief conditions of
their causation. These conditions are: a peculiar individual suscepti-
bility or idiosyncrasy; the shock of cold applied to the general surface
of the body; prolonged muscular exertion; and forcible and sudden
muscular exertion, especially in the direction of the extension of the
extremities. There can be no doubt about a liability to muscular cramp
being an individual peculiarity. The disorder is especially apt to arise
in persons of irritable temperament. While cramp has been met with
in all ages, sexes, temperaments, and climates, it has been observed
that it occurs far more frequently in warm climates than in cold, and
chiefly in the hottest of warm climates, and that persons of middle age
suffer most from the affection, and men more so than women, and the
robust and vigorous more so than the weakly. Neither can there be
any doubt that the shock of cold applied to the surface of the body,
especially when the body is unduly heated, is the commonest determin-
ing cause of the worst and most extensive forms of batters' cramp.
On this fact is founded the common prejudice against bathing when
the body is much heated. Many fatal cases have illustrated this point.
Only a short time ago a robust scholar, who was an expert swimmer,
rowed in a boat, upon a sultry evening, to a deep pool; here, with his
body glowing from muscular exertion, he plunged into the water
with the intention of taking a refreshing bath, when he was immediately
seized with general muscular cramp, so that the poor fellow was at
once drowned. That more prolongation of muscular exertion, as in
continued swimming, and forcible and sudden muscular exertion, par-
especially in the extension of the extremities, as in swimming with very
vigorous and rapid strokes, are, respectively, efficient and frequent de-
termining causes of cramp, is a familiar experience to every swimmer.
These muscular emotions, however, usually give rise only to the
slighter and more localized forms of cramp. Severe cramp is a peril
which menaces most persons with highly developed muscles. Its most
powerful and most avoidable cause is the sudden immersion of the body,
when its surface is highly heated, in water of a relatively low tempera-

The Use of Thymol and Corrosive Sublimate in Embling.—The
"Lancet" has received a short paper from Dr. J. Polak, of War-
saw, who, during the past winter, has been engaged in making experi-
ments in the anatomical school upon the best methods of preserving
bodies. An injection of a solution of thymol in glycerin and water
was advocated by Virodts in 1876, and it was with the view of com-
paring this method with that adopted by Chausser—viz., the use of
corrosive sublimate—that Dr. Polak instituted his research. He
found that thymol, like sublimate, when used in a sufficiently concentrated
form, arrested decomposition of the whole body by simple injection
of the fluid through the carotid or femoral artery, the corresponding vein
being opened. But he also found that even an advanced state of de-
composition of the limbs was arrested, and the signs of such decom-
position disappeared under the use of injections of sublimate, especially
if only spirit and glycerin and no water were used. The skin became
mummified and of a dark-brown color, and the muscles acquired the
appearance of smoked ham under ether method, and neither heat nor
damp had any deteriorating effect. But a much smaller quantity of
the sublimate injection than of the thymol was needed to produce
these results. Moreover, the color of the skin was longer preserved,
and the comparative cheapness of sublimate renders it, perhaps, pre-
ferable. Dr. Polak points out that the injecting syringes should be of
glass, owing to the action of sublinate on copper. For ordinary anat-
omical purposes an aqueous solution—1 in 300 or 1 in 500—is amply
sufficient, and is better than chloride of zinc.

Contusion in Infants.—In the "Lancet," Dr. M. C. Ratton rec-
ommends the following treatment:

Take one quart of bran meal, tie it up in a pudding-bag so tight as
to get a firm, solid mass, put it into a pot of water early in the morn-
ing, and let it boil till bedtime; then take it out and let it dry. In the
morning peel off from the surface and throw away the thin skin of
dough, and with a nutmeg-grater grate down the dry hard mass into a
powder. Of this from one to three teaspoonfuls may be used by, first,
rubbing it into a paste with a little milk, then adding it to about a pint
of milk, and finally bringing the whole to just the boiling point. It
must be given through a nursing-bottle.

The Influence of Social Position on the Death-Rate.—Since the
commencement of the present year the Registrar-General for Ireland
has included in his weekly return a table showing, in five general classes
and eighteen groups, the occupations or social position of the persons
whose deaths are registered weekly by week in the Dublin Registration
District, the annual death-rate represented by the deaths registered,
the number of deaths at each of six periods of life, and the number
from each of the principal causes of death. This table has already
supplied some suggestive and instructive information. Thus, the sec-
ond quarterly return for 1883 shows that in the thirteen weeks ending
June 20, 1883, the number of deaths registered in the Dublin Regis-
tration District (the total area of which is 24,710 statute acres, and
the population of which, estimated to the middle of this year, is 249,
853) amounted to 2,674—1,294 males and 1,380 females—affording an
annual ratio of 1 in 52.7, or 3% in every 1,000 of the estimated popu-
lation. The deaths in families of the "professional and independent
class" were equal to an annual rate of 34½ per 1,000 of the persons in
that class; in the "middle class" the death rate was 26½ per 1,000;
among the "artisan class and petty shopkeepers" it was 23½; and in
the "general service class" and the "inmates of workhouses" com-
bined it was 38½. Among the last division—"inmates of workhouses"—
taken separately, the rate was as high as 46½ per 1,000 per annum;
whereas among the subdivision of the professional and independent
class entitled "persons of rural property, not otherwise described" (numbering 15,993), the death-rate was only 18.5.—Med. Times and
Gazette.

Noted Teeth.—In a paper read at the Société de Chirurgie of
Paris, M. Magitot, says the "British Medical Journal," lately called
attention to the notching and erosions of the teeth in inherited syph-
illus, and on the relations of this disease to rickets. He thinks that
the notch is not characteristic, and states that it is never found in
some races frequently affected by syphilis, such as the Japanese and
Peruvians. According to Magitot, not only inherited syphilis, but also
all other serious troubles of nutrition, may cause diminution in the
number and size of the teeth, or delay in the period of their eruption,
but never erosion. Most frequently, the latter is caused by certain
nervous affections of early childhood, such as infantile convulsions,
especially when accompanied by general debility.

Army Intelligence.—Official List of Changes of Officers serving in
the Medical Department of the United States Army from July 29, 1882,
to August 4, 1883.—Tumbull, H. S., Major and Assistant Surgeon.
Granted leave of absence for one month, to commence September 1,
1883. S. O. 77, Department of the Platte, July 26, 1883.

Naval Intelligence.—Official List of Changes in the Medical Corps
of the Navy during the week ending August 4, 1883.—Surgeon J. W.
Coles assigned to the Naval Hospital, Philadelphia, Pa.,—Passed As-
istant Surgeon E. H. Marstaller, detached from the United States steam-
ship Hartford, and granted sick leave.—Passed Assistant Surgeon
J. F. Bramford, detached from the Naval Academy, and ordered to
the Hartford.—Medical Inspector E. S. Bogert and Passed Assistant
Surgeon N. McP. Ferebee, detached from the Navy Yard, Norfolk, Va.,
on August 30th, and ordered to the United States steamship Trenton,
September 1st.—Passed Assistant Surgeon J. D. Gatewood, or-
dered to the United States steamship Trenton, September 1st.—
Surgeon B. H. Kidd, detached from the Naval Station, Port Royal,
S. C., and ordered to the Navy Yard, Norfolk, August 30th.

Society Meetings for the Coming Week.—Tuesday, August 15th:

INTESTINAL PERISTALTSIS.

By ISAAC OIT, M. D., Easton, Pa.

It is known by recent observers that Nothnagel * has discovered that when the intestinal canal of a rabbit is bared, under salt solution, the application of a crystal of chloride of sodium is followed by a contraction of the intestinal canal. This wave of contraction always runs toward the pylorus. Some years ago I discovered† that the optic thalami, when electrically irritated, arrested the peristalsis of the intestinal movement. Since that period I have also found that the heads of the crura cerebri ‡ participate in this inhibition. These inhibitory centers not only act on the intestinal reflexes, but all the spinal motor and sensory reflexes, as I have elsewhere shown. These inhibitory centers also, by their deccussating fibers, have a crossed activity. It occurred to me that the effect of the irritation of sodium salts on the bowel would be another excellent means of determining the effect of the irritation of the thalami and crura on the intestinal canal.

With this end in view, I have made several experiments according to the following method: A bath of zinc, thirty-two inches in length, in breadth nine inches and a half, and in depth eight inches and a half, was used. This was filled to a sufficient height to immerse the abdomen of the animal, the liquid being a half-per-cent. salt solution, kept at a temperature of 37°-38° C. Under this solution the rabbit, previously etherized and bound down, had his abdomen opened. Then a salt-crystal was applied to different parts of the small intestine, and the reaction noted. Then the brain was bared with the bone-forceps, and needles, insulated by means of sealing-wax, were thrust into the optic thalami. They were attached to the secondary spiral of a Du Bois-Reymond induction apparatus. The vagi were previously divided in some of the experiments, so as to avoid any exciting influences being transmitted in that direction to the intestine. It was found that baring the brain usually inhibited the reaction for some minutes, probably due to the sensory irritation calling into activity the centers of inhibition. In fact, this procedure annihilated the reaction more fully than faradice irritation did. When a strong faradice current was passed through the needles, the reaction was usually greatly weakened. In some cases the diminution was very slight, probably due to a spreading of the current to centers exciting peristalsis. These facts explain the obstinate constipation met with in certain diseases of the brain, the difficulty being an inhibition of their movements. The relaxation of the bowels with with in certain unconscious states of exhausting fevers is due to a paralysis of the inhibition-centers, allowing the intestino-motor ganglia to assume unwonted activity. In the same manner, in children, where inhibitory centers are not fully developed, we have a similar tendency to exaggerated intestinal movement.

As the physiology of several organs has been elucidated to a certain extent by the action of drugs, I have endeavored to ascertain their effect on intestinal movement. Nothnagel has already shown that morphine, in small doses, arrests the salt-reaction, and in large doses allows it to act normally, or rather in an exaggerated degree. I have confirmed this statement. The drug I first used was atropine. In doses of a milligramme subcutaneously, the salt-reaction failed, but, in doses of three centigrammes or more, the reaction was very marked. Severance of the tissues going to a loop of the intestine allowed the loop to react feebly.

The action of atropine was studied in another manner; the animal was killed and a bifurcated cannula bound in the thoracic aorta, and the portal vein opened. Then a mixture of dried blood and salt solution was rubbed together, strained and heated to the temperature of the body and run through the intestinal wall, and the reaction noted. Then another flask filled with blood and heated to the temperature of the body was added; atropine with this solution was transfused. It was found then that the salt-reaction failed. If, now, nicotine was added to the solution, the reaction to salt returned.

The effect of muscarine was next studied. In small doses, 1/2 gr. subcutaneously, it did not prevent the salt-reaction, but always increased it. If now a milligramme of atropine was given to a rabbit which had received 1/2 gr. of Merek's sulphate of muscarine, the reaction failed. If to a rabbit a milligramme of atropine is given, and, the salt-reaction fails, then a drop of muscarine subcutaneously restores it. When the salt-reaction is lost by atropine, nicotine always restores it. I also studied the effect of eserine salicylate in small doses. When I used 0002 gr. of eserine subcutaneously, the salt-crystal caused a wave of contraction in both directions. The injection, subcutaneously, of one milligramme of atropine caused reaction to take place in only one direction.

When a small dose of morphine is injected, the salt-reaction fails. Then, if 0.03 gr. of atropine is given, the result is not changed. Or, if 0.03 gr. of morphine is given, and the bowel reacts to the salt-crystal, and then a milligramme of atropine is given, the salt-reaction still takes place. If, however, the salt-reaction fails by the use of 0.1 gr. of morphine, the action of 0005 gr. of eserine will restore it.

That there are ganglia which excite intestinal peristalsis, I think no one will deny. That Pflüger and numerous other observers have shown that irritation of the splanchnics arrests the movements of the bowels is another opinion which is axiomatic. That this arrest is wholly due to ganglia in the bowel inhibiting the peristalsis excited by the motor ganglia, can not be denied, as Houckgeest has shown that the inhibition occurs when no vaso-motor changes can be seen to take place. Having now intestino-inhibitory and intestino-motor ganglia in the intestine, the question arises, Does the action of drugs sustain this theory in a physiological sense?

* * "Centralblatt f. d. med. Wissenschaften," 1882, No. 37.
† "Journal of Nervous and Mental Disease," Oct., 1879.
‡ "Journal of Physiology."
Now, morphine has been shown by GeScheidlen,* and atropine by Rossbach, † to excite the cardio-inhibitory apparatus, and larger doses to paralyze it. Now, I have shown that both morphine and atropine in small doses arrest the peristalsis as regards the salt-reaction. Also that larger doses restore it. This similarity of action of the drugs on the cardio-inhibitory apparatus and on the intestino-inhibitory tends strongly to prove two things: first, that there is an intestino-inhibitory apparatus; second, that morphine and atropine primarily stimulate it, and in larger doses paralyze it. That atropine and morphine have a central action is shown by experiments where the nerves going to a segment of the intestine are divided and the segment responds to the salt-crystal. That atropine also has a peripheral action on the intestino-inhibitory ganglia is proved by experiments where I have transfused blood-mixtures containing atropine and prevented the salt-reaction. That the intestine was not dead was proved by the use of nicotine, when the reaction returned. It is quite evident that the intestino-inhibitory apparatus requires much larger doses of atropine to paralyze it than the cardio-inhibitory does. Nicotine, eserine, and muscarine are able to overcome the intestino-inhibitory irritation of atropine in some manner. As regards eserine, Rossbach has shown that physostigmus simultaneously causes a strong irritation of the cardio-inhibitory and cardio-motor ganglia, and that in their contest sometimes one set of ganglia, and at other times the other set of ganglia, obtain the supremacy. In the small doses that we used the intestino-motor ganglia always obtained the control and overcame the stimulation of atropine on the intestino-inhibitory apparatus. With nicotine, Truhart and Schmiedeberg have shown that it also is a cardio-motor excitant. In the dose used by me, it was a stimulant of the intestino-motor ganglia.

Schmiedeberg ‡ and Koppe have demonstrated that, while muscarine is a stimulant to the cardio-inhibitory apparatus, it is also a cardio-motor stimulant. In the doses used by me of Merck's muscarine it was an intestino-motor excitant. In experiments where eserine was first given it was found that atropine could only partially overcome the excessive action of eserine, for, when the salt caused a wave in both directions from it, atropine restrained the wave in one direction. Muscarine also overcomes atropine. It was quite evident that the relation between the cardio-inhibitory and the cardio-motor ganglia on the one hand was somewhat different from the relation between the intestino-inhibitory and the intestino-motor on the other hand. The inhibitory ganglia of the intestines have less control over the intestino-motor ganglia than the cardio-inhibitory have over the cardio-motor. It is also evident that the action of drugs on the intestinal canal will throw light on the rôle of the cardio-motor ganglia, just as the action of drugs on the heart illuminates their action on the intestinal canal. From these experiments it follows: 1. That in the optic thalami and crura cerebri are inhibitory centers restraining the intestinal reflexes. 2. That drugs may be divided into intestino-inhibitory and intestino-motor. 3. That morphine and atropine in small doses are intestino-inhibitory agents. 4. That eserine, nicotine, and muscarine are intestino-motors.

BRAIN IRRITATION.

Experiment I.—Rabbit etherized, abdomen opened, electrodes inserted into base of brain. The intestine previously responded, but, after faradic irritation, the bowel acted less rapidly and extensively.

Experiment II.—Rabbit etherized, skull opened, corpora quadrigemina laid bare, needle electrodes inserted at the union of the crura and optic thalami; faradic irritation. Then salt-crystal had hardly any effect on peristalsis.

Experiment III.—Rabbit etherized, skull opened, vagi divided, corpora quadrigemina bare, abdomen opened; intestine reacted to salt-crystal; needle electrodes were inserted into head of crura, and an induction current passed. Salt-crystal acted very feebly.

Experiment IV.—Rabbit etherized, vagi divided, brain bare, abdomen opened, but intestines did not act for about five minutes; needle electrodes inserted into thalamus and crura. The reaction to salt was more feebly.

Experiment V.—Rabbit etherized, intestines exposed, skull perforated over the thalami and needles thrust into them, and the salt reaction failed for some time. After a while it returned, and a weak faradic current was passed through the base of the thalami, and then the salt-reaction was enfeebled.

ATROPINE.

Experiment VI.—Rabbit etherized by subcutaneous injection of ether; abdomen opened under salt-solution; salt-crystal caused active movement. A milligramme of atropine was given subcutaneously, and in ten minutes the salt-crystal did not cause any action. Then a drop of muscarine sulphate was injected subcutaneously, and in about ten minutes the intestine responded normally to the salt.

Experiment VII.—Rabbit etherized; received 0·1 gramme atropine subcutaneously; the intestine, which previously responded to the salt, did not act. Then a loop of the intestine was ligated, the vessels going to the loop were broken up, and then the salt-crystal was followed by a movement.

Experiment VIII.—Rabbit etherized, intestine exposed; salt-crystal caused peristalsis; 0·2 gramme atropine subcutaneously; salt caused more action; 0·14 gramme atropine subcutaneously, when the intestine responded to salt-crystal.

Experiment IX.—Rabbit received stab in medulla; chest opened, cannula inserted into thoracic aorta, blood-mixture and salt-solution run in under 100 mm. (mercury) pressure; the peristalsis was active. Then ten drops of atropine solution were added to half a pint of blood and salt solution and run into the thoracic aorta. The intestine soon failed to respond to the salt. Afterward one drop of nicotine was added to a half-pint of blood, and the intestine commenced to move quite actively. The rabbit's abdomen was immersed in salt solution.

Experiment X.—Rabbit killed; cannula inserted into thoracic aorta; blood-mixture well agitated and run in under 100 mm. pressure; intestine responded to salt-crystal. Then 0·025 gramme atropine added to a pint of blood. After a few minutes, intestine did not respond to salt. A drop of nicotine was added to half a pint of blood and transfused, when the small intestine set up active movements. The rabbit's abdomen was immersed in salt solution, at 38° C.

Experiment XI.—Small rabbit etherized; received 0·005 gramme atropine subcutaneously; in about half an hour the salt-crystal had no effect. Before the want of reaction came on the

---

† "Pharmakologische Untersuchungen," Heft 1.
‡ "Das Muscarin," Leipzig, 1869.
latent period was increased, and the extent of the contraction along length of the intestine was slight.

Experiment XII.—Small rabbit etherized; bowel reacted; 0.005 gramme atropine given subcutaneously. After about half an hour the bowel did not react. Then the blood-vessels and veins going to a segment of the bowel were ligated very tightly. After some time the segment of intestine reacted to salt-crystal, while the remaining part of the bowel did not.

Experiment XIII.—Rabbit etherized; peristalsis active to salt-crystal; 0.01 gramme atropine given subcutaneously. After about half an hour the salt acted feebly. Then part of the intestine and vessels were ligated. Salt acted quite well upon the isolated section.

ATROPINE AND MUSCARINE.

Experiment XIV.—Rabbit etherized, then a milligramme of atropine given subcutaneously. In ten minutes the salt-crystal was without effect. A drop of muscarine sulphate was given subcutaneously. In ten minutes the intestine responded as it did before.

Experiment XV.—Rabbit etherized; 0.2 gramme atropine subcutaneously. After considerable time the salt did not act. Then 1 gtt. of muscarine was given subcutaneously. After a long time the intestines seemed to act.

MUSCARINE AND ATROPINE.

Experiment XVI.—Rabbit etherized; received at 1.50 p.m. 1/2 gtt. of muscarine sulphate; 2 p.m., intestine reacted normally; received 1/2 gtt. muscarine; 2.10 p.m., intestine reacted quite readily. Then 0.01 gramme atropine subcutaneously; 2.25 p.m., no reaction to salt-crystal; 2.35 p.m., 1 gtt. muscarine sulphate subcutaneously; 2.45 p.m., intestine slowly reacted to salt.

ESERINE AND ATROPINE.

Experiment XVII.—Rabbit etherized; received by jugular 0.005 gramme of salicylate of eserine; peristalsis was much more active when salt was applied. The wave of contraction ran in both directions.

Experiment XVIII.—Rabbit etherized; received subcutaneously 0.002 gramme eserine at 4.20 p.m. At 4.28 p.m., when salt was applied, the wave of contraction ran in both directions; 0.01 gramme atropine subcutaneously; 4.40 p.m., reacted in only one direction and slowly to salt; 0.01 gramme atropine subcutaneously; 5 p.m., reacted, as before, in one direction only.

MORPHINE.

Experiment XIX.—Rabbit etherized; 0.2 gramme of morphine sulphate given subcutaneously. In about twenty minutes the intestine did not respond to salt; then 0.03 gramme atropine was given, but no action by the salt. Then 1 gtt. of muscarine sulphate given; still no response.

MORPHINE AND ATROPINE.

Experiment XX.—Rabbit etherized; received 0.035 gramme morphine sulphate subcutaneously. In twenty minutes the salt-reaction was marked; 0.02 gramme atropine given subcutaneously. The salt-reaction was still present twenty minutes after the dose of atropine.

MORPHINE AND ESERINE.

Experiment XXI.—Rabbit etherized; received at 12.45 p.m. 0.01 gramme morphine sulphate subcutaneously. At 1.05 p.m. there was no salt-reaction. At 1.05 p.m. 0.005 gramme eserine was given subcutaneously; 1.12 p.m., there was marked reaction to salt-crystal.

ON CAUSES OF MELANCHOLIA.*

By GEORGE BAYLES, M.D.,

ORANGE, N.J.

For the scientific observer of the present day, human pathology has a field which is bounded by no visible horizon.

One step forward enlarges his working area, but does not limit the apparent extent of his unexplored surroundings. This truth is borne in upon the mind at every turn, but never with such vivid clearness as when searching for light in the department of the neuroses.

New visions, cross-lightts, and spectra come crowding in under every impulse of serious study, and they must be comprehended, or at least noted, ere they are gone beyond immediate recovery. What is known in medical science beyond the possibility of an error is doubtful of the least value and practical importance as compared with what has yet to be known, and which shall be known.

What stimulus and encouragement for the scientific student!

A little reflection will show how this prediction bears upon that large class of diseases which we have been inclined to think have not yielded very profitable results to investigation, the study of which has not been quite satisfactory. Diseases about which we think there is little more to learn have served for pioneer study in the days gone by, and have come to be regarded as having an unvarying history unless complicated by some intrusive accident.

Cause, advent, course, and treatment are all as precisely noted and as conventionally formulated as the terms of a problem in elementary mathematics. All this is sufficient for our needs concerning this primordial class of familiar idiopathic affections, but will not apply to the mystic department of neuroses. Fixity, conventionality, and formulation will not lend transparency and aids to comprehension to the department of neuroses. Here we confront a variable etiology, an often disguised advent, a problematical course, and a tentative treatment. The element of uncertainty is the prevailing one, and, for a time, facts must stand, in a measure, undemonstrated, until tests for error have completed their mission. The erratic character of the neuroses shows conclusively to what peculiar order of the functions of life the expressions of disease in organic life owe their origin. Causes which give normal or abnormal impulses to the source and centers of nerve energy are as variable and as numerous as the events of life in the world; hence, the erratic nature of neurotic manifestations is due to variability of causes on the one hand, and, on the other, to peculiarity of the subject under the influence of the causes of neural excitation and disturbance. There are probably few, if any, of our number who have not been interested in states of mental depression from, perhaps, every standpoint that could engage the attention and sympathy of the kinsman, friend, neighbor, and physician. This common experience has afforded us a substantial acquaintance.

* Read before the Medical Society of the State of New Jersey, at its annual meeting, held at Atlantic City, June 12 and 13, 1883.
with many forms of mild mental disorder, as well as some that possess the graver characteristics. This acquaintance will assume the dignity of knowledge, by and by, when study progresses and nature and science unfold. If we are to begin at the beginning, our present interest will center in the aetiology of these deviations from mental integrity and normal order. Causes that predispose to mental disquietude are often obscure and not readily discernible. This, I believe, is true of all remotely predisposing causes. With regard to causes that date back of those that are immediately exciting we have a field open to honest research, with promise of great reward. At this point we will be at work upon the very foundation of our subject and the point chosen for the few practical thoughts offered, I trust with modesty, in this paper.

The earliest causes will be a rare field for speculation, but it will be also a field that will yield good fruit for patient and honest toil.

The timeliness of a study of the more remote causes of mental depression will not be questioned when we consider the alarming prevalence of melancholic mania under the benign circumstances of national peace, general plenty and prosperity, and the wide-spread communal comfort which we now enjoy, when we reflect also upon the fact that this great wave of mental perturbation can not have received its impulse from any unusually distressing social or political excitement.

Spared the horrors of war, pestilence, famine, and exceptional financial distress (each of which is an affliction pregnant with personal woe and sorrow sufficient to dethrone the sound reason of many, even of the strongest), the great cosmic causes—so to speak—of mental discomfiture are not in general operation. We, therefore, must look elsewhere for some besetting or abiding cause of so wide-spread and grievous a visitation of mental disturbances as we now observe. The mental states under review for their aetiological incitements range through mild hypochondriasis, limited melancholia with torpor or with destructive tendencies, or melancholia with persistent excitement of the will. Other states of mental disorder may be included, however, in the list of such as are liable primarily to be induced by the same remotely predisposing causes. All states of mental irritation or depression are liable to be ushered in by the same specific though distantly remote cause. This cause may give rise to only slight functional errors of reason and will-power such as frigate the borders of positive insanity, but the limit of the basis will not invalidate the theory, because what consequentially results of more serious character are only later stages or developments of the same perverted conditions. Abnormal action of the mental organism tending to melancholia exhibits a malady of the mind that explodes into violent and destructive agitation or lapses into lunacy long before it may with reason be suspected that the border-line of insanity has been reached, much less has been crossed.

Mental states such as are clearly morbid and progressive toward the point of positive derangement concern us much as to their aetiology, for the reason that so much depends upon efficient prophylaxis, and so much less upon the means of cure at our command.

Age, sex, and social condition afford our statistics no essential variation in the allotment of this deviation from standard or normal mental health among mankind during periods of social, political, and religious tranquility. We learn to look to individuals for physical conditions affording evidences of a law of differentiation as to kinds and gravity of all the disorders classed under the head of mental depressions, and this same direction of observation will be the most promising for some law of prevalence. This suggestion seems to point to a fact of special significance, and is an aid, by their simplification, to our studies in this department of mental maladies.

We will not excite contradiction by the broad statement that the condition of the body influences the condition of the mind quite as uniformly as the condition of the mind influences that of the body. Action and reaction between associated mind and matter has never, we suppose, been seriously denied or doubted. That a healthful mind will always be the most wholesome aid to correct bodily functions we suppose to be quite established. There are certain forms of depravity of the body that must affect the mind, and, per contra, there are certain forms of mental alienation that have a very powerful effect upon the body. Physiologically, or pathologically, as the case may be, these mutual interests of mind and matter, as between mind and the corporeal body, are ever present and of the greatest importance. There is a certain mutual dependence which is constant and often conservative, and there are certain dependencies which may, without prejudice to either, be dissolved. These we will not attempt to define upon any extended scale. The dependence, however, which we consider as constant is that which we apprehend will furnish us with our elew to the early, perhaps the earliest, remotely predisposing cause of melancholia. The correct working of the mental forces, we believe, depends primarily upon perfect cerebral nutrition. It is upon this thesis that we base all that follows in this dissertation.

By freeing our minds, for the time being, of all impressions suggested by the secondary or immediately exciting causes of melancholia, we will be left untrammeled to pursue our researches for those states which lead up to the point of readiness or preparation for the potent action of the secondary influences. Minds with an armory of invulnerability to secondary assaults, through any channel by which the assailing powers may approach, show conclusively that the first source of weakness, or rather the first for weakening, has been equally impotent and inefficacious. An efficient first cause is all that is necessary for the successful operation of the later or secondary causes.

The earliest point at which our thoughts can advantageously start are the pre-natal conditions of life with reference to brain nutrition. Without any superstition relating to maternal impressions, we are convinced that whatever weakens a mother's brain-power will weaken that of her child, during the formative period of its cerebral organs in utero. Often, indeed, a feeble-minded child will issue from a strong or healthy-minded woman, or the exact opposite may occur, and these may be exceptionally singular cases. The operation of debilitating causes of brain-power in these cases has
been unequal. Physiological law, therefore, incidentally and occasionally reverses the pathological law. In the vast majority of cases, however, the more malign law holds good, and no benevolent law steps in with force enough to protect against mal-influences.

The contents of the gravid uterus had a period in the history of their development when their atomic entity was an essential derivation from maternal elements, and doubtless (as in the period of differentiation of sex) it is then that the maternal stamp of mental power or weakness, and all its eccentric combinations, is placed upon the germ of human life. This atomic entity which we term the ovum is then liable to changes such as fructification or impregnation, implantation in the cavity of the uterus, and all that follows in course of gestation. The least change which may occur may be its simple migration outward unpregnated, and its exit with the catamenial flux. This change, ending its physiological history, calls for no consideration.

The changes in the course of development, however, are of the first importance. Impregnation doubtless stamps a character of some sort. It may re-enforce previous tendencies that have been derived from maternal sources, or it may obliterate previous tendencies, and it may introduce tendencies of an entirely new nature, such as may result from combining initial tendencies received from both parents. What dire combination of antenatal circumstances served to furnish the world with a Nero, a Borgia, or a Guiteau it would be interesting to know. Apparently they were born as free of moral corruption as many people who never did a grossly evil thing. In natures capable of as deep defilement as belonged, in later life, to these human demons, the seeds of villainy must have been implanted deep in the subsoil of their natures, awaiting the time of natural development, or the touch of the right passion to ignite this magazine of hellish fires. The seed can not change its nature any more than the leopard can change its spots. The fiat of original tendency has gone forth when the ovum is elaborated and dislodged from its nidus. It is subject to changes if it should meet potent influences, but if the influences are insufficient, or practically negative in the direction of improvement, its original condition will always prevail. This vein of thought in the region of embryology is, perhaps, highly speculative, but we think it not unreasonable, and not discordant with our present light on these subjects.

In the case of the mother there is a certain health which is organic health, and may be compared with a normal vegetative vitality. In this, the ovum, and, later on, the fetus, may participate. It is almost certain that they will. Besides this, there is a health that is something above mere physical integrity. It is described by terms, which, though, meaning much the same thing, have, perhaps, slight differences of verbal significance—endurance, buoyancy, "staying power," resilience—in a word, something that furnishes a hold upon life superior to what is common, or which is necessarily a part of simple organic life and physiological correctness. When this exists, it will be of equal advantage to the fetal life and to parental life. The absence of this higher order of health is sure to deprive the egg, and the fetal product of the egg, of just that special quality of health that would lift it above the gross animal issue of mere organic health. It is common nature in the one case, while it is sublimated nature in the other. Do you doubt this distinction in your comparisons of the results in life of the influences of offspring from the low, vulgar classes of the world, and of the refined, moral, intelligent, and cultured? Do you begin precisely upon the same basis with each to divine the results of certain fixed agencies, and do you have the same rate of progress with each and all in the general scheme of education and submission to just and human laws? We think we are not far from the truth when we say that a good life or a bad life, so far as its initial bias is concerned, begins within the corpus luteum. This maternal influence or diathesis has, then, at this point, independently of all other influences, a feature resembling psychical foreordination. If it were not so, we fear our State might well lose hope and encouragement in what it undertakes for the moral and mental benefit of the masses, and our domestic system would not find advantage, safety, and comfort in the order and excellence of the true family relations. We may easily dismiss all this theorizing without impairing our line of reasoning; yet, if this very primitive point is not deemed fallacious, it greatly strengthens our argument and the logic of the historical events under review. The better the soil nurturing the seed, the better will be the fruit of the seed. The analogy is perfect, we suppose, throughout nature. How much the fructifying agent may occasionally impair the original value of the seed and pervert its tendencies is not yet known. That it may do so in some instances there probably is some evidence to prove, but not, however, such strong evidence as bears upon the fact that an originally bad or imperfect seed can be very greatly improved by the fructifying process. In general, the seed will develop, in due order of physiological action, after the fructifying event, but the primal stamp has probably not been greatly changed for the better, though it may have been changed for the worse. This tendency toward retrograde action is that which we must strive to arrest and reverse, if we wish mankind to emerge from much of its innate or inborn moral and intellectual depravity. The lesson of all this is the unqualified necessity of the pre-natal excellence of the germ of future life, and, more than that, the necessity for the goodness or excellence of that germ before fecundation, as fecundation can do but little, if, indeed, it can do anything, in altering the bias already implanted in the secret nature of the living germ. Now, the nature of the mother, by her instinctive state and her education, establishes, first, by a powerful factor, the future brain-status of her offspring. All that follows of the nature of guiding influences is auxiliary in the right or the wrong direction, according to the original tendency, and is powerful or feeble to modify and alter original conditions, according to the amount of original susceptibility. "Like begets like," therefore we look to the mother for a solution of what sooner or later shall befall the offspring. How to arrange the life and surroundings of the mother with reference to the welfare of her offspring belongs to the higher departments of hygiene, and opens a field for study and practice with which we may candidly say we are little familiar. This department will be brought into
great prominence as time goes on and we become better acquainted with antecedent influences.

We are keenly alive to cause and effect, and we shall inevitably drift into this interesting branch of observation at a time not very remote. Our social organization is our best field of enterprise. With reference to the moral and physical welfare of children yet to be born, not less than for those already in the world, purity of life, sternness of character, refinement, tenderness of all enerving influences, high aim, relief from drudgery, tasteful situations, religious principle as against impurity, carelessness, vulgarity, roughness, and cruelty, low purposes, slavish toil, distasteful adaptations, absence of religious motive, and sensitiveness, are the telling elements that determine the nature of offspring. As in the physical, so of the moral nature are these conditions most positive in their effects. In all such cases these conditions are necessarily combined, and the most erratic results are inevitable. If they which are good exert their influence upon the germ of a forthcoming new life, well and good. If they that are evil do likewise, what enormous evil! If these conditions are mixed, what strange perversions of nature result! That they are most generally of a mixed order we may well believe when viewing the anomalies of human life and character.

How far we will go with Dr. Ball depends upon our individual experiences. In a recent interesting lecture on "The Frontiers of Madness," delivered by Dr. Ball in his course at the Paris Faculty of Medicine, he says: "The generally received opinion that folly and reason are separated by a strictly drawn mathematical line is quite erroneous. There is a broad frontier between sanity and insanity, which is peopled by millions of inhabitants." He holds that the number of persons perfectly reasonable on all points throughout the entire period of their existence form but a minority of mankind. The world abounds with people, he tells us, whom a strict scientific diagnosis would condemn as mad, or more or less "touched." Yet at no time of their life would it be permissible to put them under restraint. "Such persons are to be seen occupying honorably and successfully every position in life and society; we brush against them when we take our daily walks abroad; we see them in the mirror which reflects ourselves."

Most certainly it is a mal-nutrition or innutrition that must be regarded as the causa primaria of cerebral or nerve dyscrasias. Our light is bright on this subject in post-natal relations, and it is inferentially luminous on pre-natal relations of this character.

Presumably, where no real disease is present with the mother, the principal if not the only check upon correct nutritive processes within the generative zone is emotional. We well know the effect of the emotions and sympathies upon the digestive processes. High excitement or long-suppressed emotions have a very direct influence upon the important organs of the body belonging to each of the great systems of organic functional activity. The generative system can by no means be exempt from this law. Indeed, it may yet be shown by the exact histologist that the generative system is the most susceptible of all the systems to impression and change under emotional and other exciting influences. The center of a new life, such as the germ contents of an ovarian vesicle, will doubtless bear some corresponding relation as an impressionable nerve-center. [As the great centers of parental life: viz., the brain and the heart.] That great center associated with the dual life of mother and germ is, we well know, a seat of great changes and perturbations under the stimulus of emotions. The exalted nerve-action that can produce an orgasm or erethism (which never expires or expresses itself wholly locally) is second to no function prompted by nervous influences in the whole animal economy.

Doubtless the generative zone is the center of stronger and more effective nerve-action than elsewhere; and, if this is true, these checks and stimuli through nerve operations are more effective there than elsewhere. The effect upon local nutritive action would be obvious. This would, indeed, be the peculiar direction for the expenditure of important and exceptionally forcible nervous agitations. Arrest of development, either temporary or permanent, or the impulse given toward unequal development, would, therefore, be the reasonable and probable result of mental perturbations if the female upon the initial germ of infantile life held in her possession. We know something of the effects of a sudden overwhelming of nerve-force in a child when the victim of a spasm or convulsive fit. Long years after the incident the dentist will assert that the teeth: demonstrate such an event having occurred. If we could search into the deeper recesses of the body with profound anatomical skill and ready apprehension, we should doubtless find many such evidences of arrested or disturbed development in the structures and tissues.

No grand disturbance of the normal action of the organic life can be held blameless of some corresponding alteration of tissul development. Arrests of development, however brief, must require a renewal of evolutionary action, under new and sometimes very different conditions, when development is resumed. The accident of arrest or deviation of development must amount to a perversion of normal development, and hence will be, to a more or less degree, structurally prejudicial. Perfection has been assailed and, in truth, dethroned. If this is liable to happen in average good lives, what must be the consequences in vicious or ill-conditioned lives?

The outcome of this line of reasoning, if not at variance with truth and the facts as we understand them, is to show the necessity of right living, right thinking, right feeling, right associations, and a right appreciation of our personal responsibilities. Our women are the seed- and fruit-bearers of our race. They must be protected and nurtured and governed as we have never heretofore supposed to be necessary if we wish to realize perfection, in even a corporeal sense, in their maternal issues. The unfolding of sanitary, hygienic, educational, moral, and religious responsibilities under this view is enormous. They may well appall the easy-going man of drugs and routine prescriber of the present time. They may well startle the listless, unimaginative parent of this generation. They may well-nigh paralyze the superficial social economist, and dismay the complaisant purveyor of modern religion. All have a new thing to
realize. All have a new system to organize. All have new motives for uniting activity in directions as yet little dreamed of.

There is attainable a sort of earthly perfection standing somewhere beyond our immediate reach, but held as a reward of merit to those who recognize the fact and strive to obtain the prize. The pioneer movement has been too long delayed; let us begin, and our posterity will reap the benefit. Long years may follow those of the past before anything like such physical perfection and intellectual exaltation is attained; but, if every work shall be completed before the world shall be obliterated, then we may expect to have great physical and moral excellence upon the earth at some unknown future time. Every little step in the right direction brings it nearer. Leaving these flights of sanguine fancy, and settling down to our present basis of operations, we have to inquire what happy conditions will bring the best results to offspring in this and immediate generations as regards the nerve-force and mental soundness of those yet to be born? What will best antagonize prevailing deteriorating influences? The woman about to be a mother should be in sublime accord with all of nature's best laws. Her life, both corporeal and mental, should be a bulwark against the invasion of conditions detrimental to the perfection of her offspring. The very essence of her life should neutralize all noxious elements. She should start with good physical health, which should be preserved with such care as is bestowed upon no other object. Failure in this respect should not be due to ignorance, heedlessness, self-indulgence, or over-confidence in the harmlessness of petty things.

(To be concluded.)

REMARKS ON CODES OF ETHICS.*

BY

ALFRED MERCER, M.D.,

PROFESSOR OF MEDICINE AND CLINICAL SURGERY IN THE MEDICAL DEPARTMENT OF SYRACUSE UNIVERSITY.

Ten years ago I discussed at some length the question of consultation with irregular practitioners. In the closing paragraph of that paper I stated: "From all that we have said, and from all that we have thought on the subject, I believe it is our duty to remain just as we are." Principles have not changed, but our surroundings are constantly varying—the world of medicine even does not stand still. It may not prove to be best to make any change in the law of consultations, but it is right and proper to still further discuss the propriety of making a change. Although much has been said on the subject, it is by no means exhausted. It is a subject that can not be disposed of in a summary way. It can not be stifled by pledges to stand by the old code—thus gagging discussion—to gain admission to any medical society. This is an "irresistible conflict."

I do not wish to press to a vote to-day the resolution I am about to offer. I wish to hear it discussed, in view of all surrounding facts, without prejudice or passion, that we may arrive understandingly at a just conclusion. Up to this time I have cast no vote on the code question in any society during the present agitation, not being convinced as to what it was best to do under the circumstances.

The question must come up at Albany in February next. We have more time to discuss it here than we shall have there, in order to arrive at a right understanding as to how to vote. Discussion may change the opinions of some of us. I would offer the resolution, in the spirit of compromise, harmony, and good-will, to all educated, well-meaning medical men, of whatever faith in therapeutics. Yet I shall speak freely in praise or condemnation of the good or the evil that I see in the profession. I would be glad to unmask hypocrisy, the evils of the profession, and the wrongs we do, thus causing the evil to point the way to higher morals and higher duty.

Resolved, That, in view of the present condition of medical practice, it is the sense of this society that the interests of the public and of the profession will be best served by the abolition of all codes.

Mr. President: I do not offer this resolution because I have lost faith in the principles of the old code, although I may have lost some faith in its usefulness in accomplishing the purpose for which it was adopted.

It is not always proper or judicious, it is not always the best thing to do, to further even a good cause, to put the best thoughts of the wisest of men into law. Great changes have taken place in the medical world, outside of and within the limits of the regular profession, since the adoption of the old code.

Surveying the whole field of medicine, seeing things, I believe, as they actually are now, I am of the opinion that any code, of whatever description, is more likely to do harm than good. The old code has always been a target for the shot and shell of the lay press, for ignorance and prejudice, for quacks, learned or unlearned, for mountebanks and impostors of all grades of stupidity and villainy. Abolish the codes, and you will destroy some of their stock in trade, by which they make capital against honest medicine by the cry, "exclusive, exclusive, bigot, bigot."

When the old code was adopted there were none but regular medical schools in the country. The knowledge which the outside world then had of medicine it picked up as best it could. Now these outsiders have more than a score of schools, whose announcements as to time of study, the text-books used, and the branches taught, will bear a favorable comparison with the announcements of our own schools.

I quote from an announcement of one of these schools: "Experience has established the law similia similibus curantur as the grand guide in therapeutics; and yet, believing the domain of the law more or less limited, they also, in harmony with the principles of true progress and American institutions, have a breadth and comprehensiveness which do not exclude any thing or any measure which experience has demonstrated to be instrumental in relieving human suffering and saving human life." I think we could all admit to fellowship a physician and a college holding these senti-
MERCER: CODES OF ETHICS.

MEMENTS so proclaimed to the world. Men holding these sentiments, and proclaiming them to the world, are proper candidates for membership of this society. There may be such in the society already.

Here I might ask a very important question: Why were these schools organized and brought into being? It was supposed that our schools taught everything known or that was worth knowing in medicine. Why, then, were these schools organized? Were they a necessity? Did they fill a vacancy, or supply a want? Were they organized to elevate or lower the standard of medical education, or give a new direction to medical thought and inquiry? All these would be interesting questions to discuss at length. I feel that I do not possess sufficient knowledge and data to discuss them intelligently, and perhaps for our present purpose it is not necessary to discuss them.

We know that these colleges exist by law, and are likely to continue to exist, with full powers to grant licenses to practice medicine. It is of no use to think that these colleges ought not to have been chartered; they are chartered, and are turning out hundreds of graduates annually, to stand side by side and shoulder to shoulder with us before the public.

A very different state of things from that which existed when the old code was adopted, these new conditions force new problems upon us for consideration. The new "living present" is very different from the "dead past" of forty or fifty years ago.

We hear much of the time-honored usages of the profession—that the good and the wise support the old code, and that we must submit to the centralized power of the American Medical Association in regard to ethics, etc. We must discuss this subject on its merits, and not from any of these standpoint, in order to determine whether it is best to stand by the old code, or the new code, or to abolish all codes.

Here I must ask after the character and quality of the graduates of these outside schools. This I can not answer. But this brings us to a subject that is of much greater importance to the public and the profession than any code, old or new—the kind of graduates turned out from all the schools of the country. The public and the profession should demand a new order of things in granting a license to practice. Confine the power to grant a license to practice to a State board of examiners, and let that examination be thorough and exhaustive; then we shall know that the legally qualified practitioner is our peer in knowledge and a fit associate for consultations, unless cut off by gross immoral practices or quackish proclivities.

The grounds upon which the regular profession has refused consultations have been ignorance and the practice of medicine under some sort of fraud or deception, or some unproved theory or dogma.

The refusal to consult with the outside world of medicine on the score of ignorance has passed away, or is rapidly passing away. I wish I could believe so as to say as much in regard to the practice of fraud and deception.

Although I am in favor of no code, for the present at least, the principles of honor and justice embodied in the old code will be just as binding on the conscience as ever.

"The leaf may fade and the marble may crumble," but the principles of the old code will endure for ever—knowledge, truth, liberty, and honor, against ignorance, fraud, deception, and dogmatism. The world—the Christian world, even—is not yet educated up to the "higher law" of the old code. No wonder that it is every now and then broken by frail medical men, even though they advocate the old code. We can not escape the code of honor and intelligence if we would.

I am of the opinion that the new code makes a sort of semi "Missouri compromise" with sin. It abandons the "higher law" of the old code, and steps down to accept questionable legal enactments. It does not say we shall, but we may consult with all legally qualified practitioners. It recognizes the legally qualified doctor as our professional equal.

Although they may be educated, where and what is the honor of many of these legally qualified practitioners? The old code, or no code? The "higher law," or no law in consultation! Meu still shout "Hahnemann! Hahnemann!" and prescribe medicines on the principles of Hippocrates. Shall we strike hands and embody into law that we may consult with this fraud? Better let the law of consultation be unwritten, only as it is written on the conscience. Others shout "Eclectic! eclectic!" cry "Wolf! wolf!" where there is no wolf. The regular profession has always been eclectic, using all things, discounting nothing, that could benefit the sick. It thus appropriates, with a free and open hand, all the good of homeopathy—it would be recreant to duty if it did not. Is there anything wrong, any deception, fraud, or robbery in this?

It is fair to assume there can be but one medical science. Hahnemannism has been on trial for nearly a century. Is this not long enough to test its merits and establish its truth?

Has it ever before required a century in an enlightened age, with thousands of earnest seekers and workers, to prove to or to convince the world of a scientific truth? Is homeopathy an exception to this rule? Hahnemann could not possibly have written his "Organon" in the light of the science of to-day. The microscope has exploded his psoria theory. The schools bearing his name teach general pathology and pathological anatomy, which is nonsense if the totality of the symptoms constitutes all there is of disease. Infinitesimal dosing is by no means uniformly followed. All there is left of Hahnemannism is a small remnant of the claimed law similis similibus curatur. Yet this little is tenaciously clung to as of the greatest importance. It serves, at least, to keep up an opposition to scientific medicine and make a class distinction. Is it fair, is it honest, to announce to the world that disease is treated by the rules of Hahnemann, and then treat it by some other method? Where is the honor of a constantly broken promise? But bad promises are better broken than kept. May not the Hahnemann promise be of this nature? All "regular" prescriptions made under the homeopathic flag go to the credit of Hahnemann, and thus scientific medicine is cheated and robbed of her just dues.
But most of these men seem to think there is nothing wrong, no evil, no injustice in this. Nevertheless, every honorable man knows that such conduct is wrong, although it may conform to the ordinary "morals of trade," which permit of advertisements that every one knows to be false, and which deceive but few. These gentlemen might ask, Why should the morals of medicine be better than the "morals of trade?" The "morals of trade" should be better than they are. Most men can discover the frauds of trade; but it requires an educated medical man to point out the frauds of medicine. The public are at our mercy in regard to fraud, and our morals should be above suspicion or reproach. Assuming that the irregular physician is educated, to my mind this item of morals is the great stumbling-block in the way of consultations. Outside of this moral obliquity in medicine, his morals and conduct are above reproach. It seems strange to the public, and they can not understand, why we should refuse professional intercourse with these, to them, honorable educated gentlemen. If the homœopathists would say to the world—although we believe in the Hahnemann law of cure, yet, as now developed and understood, it is not equal to all emergencies, and we are, therefore, at times obliged to resort to regular medicine—this would largely dispose of the moral question; then how should we stand in actual consultations, ignorance and morals out of the way? I assume that these men are educated, and are competent to compare their observations with ours in diagnosis. Here we could hold a scientific consultation as to treatment. I expect, when regular medicine is called in, most of the cases have passed beyond the limits of the Hahnemann law. I never heard of such a meeting or consultation—and I have heard of a good many, and have made some myself—where Hahnemannism did not yield to regular medicine. Many of these consultations have been held with homœopathists when everything was regular. Some claim that such meetings are not consultations, the regular making an independent diagnosis and prescription, leaving the homœopathic doctor to act as nurse. It is said that consultation with homœopathy is an impossibility, and can result in no good; that it is a fraud and a cheat to accept a fee for such pretended consultation. If such medical interviews, not to say consultations, result, as they generally do, in science supplanting the dogma, they are productive of some good; they are not frauds, and the physician is worthy of his fee; besides, scientific medicine might possibly learn something from homœopathy—or are we too wise to learn? If the patient understands the tenets of doctors, and wants the opinion of any one of them, it is no fraud to give it, and accept a fee for the opinion.

With no binding consultation code, it is a question whether this liberty would be abused to the detriment of the public or of the profession. No great harm can be done by trying the experiment. If evil comes, we can re-enact the code. Medical science will survive the shock.

Homœopathists complacently survey the field of medical ethics, and smile at our squabbles, alike indifferent to our praise or censure. The important question between them and us is, Are they true to their principles? There can really be but one science of medicine. The soil on which it grows, the roots, the trunk, and branches, are all the same; our individuality may crop out in different buds and fruit. We differ only in the application of the science. These differences may possibly be classed as schools. I believe the gap that separates educated medical men in practice at the bedside is very small compared with what it seems to be on the surface before the world.

Although these lines are sharply drawn before the world, I have found that they fade out at the bedside. I believe, in practice, the antagonism, the non-intercourse existing between "regular" and irregular physicians is altogether unwarrantable. The irregulars have fallen into ruts of opposition to "regular," honest, liberal, scientific medicine, and would seem to continue this opposition without any sufficient reason—an opposition based, it seems to me, largely on caste and pride of opinion. Both parties, perhaps, are maliciously obstinate, and determined to keep up the war.

I believe among well-educated men the real differences are so slight that, with a little Christian kindness and charity, a little giving up and a little coming down on both sides, we can meet in harmony at the bedside for the good of the patient. There is some perverseness, something wrong somewhere, that we should be so far apart when we are so near together. I believe some way can and will be devised ere long by which educated medical men will come together. It is only a little remnant of the theory that like cousins like and obstinacy that keep us apart now. But opposition is the home of some men, and the only place where they can thrive or be happy.

The abolition of all codes may be an honorable step, certainly not a dishonorable one, for us to take in the direction of harmony. This is the only olive branch of peace the regular profession can offer to the irregular profession. But most of the irregulars do not want peace; they desire and thrive under opposition. With no code we offer no opposition, and they will find little to fight. It may take years for bitterness of feeling to die out. Any overtures for peace where peace is not wanted may be spurned with words of contempt and insult, but men can not stand for ever in a false position, even in medicine. Sooner or later the "sober second thought" of truth will prevail.

[The following account of the discussion has been kindly furnished by Dr. D. M. Totman, secretary of the Medical Society of the County of Onondagas.]

After the reading of Dr. Mercer's paper, Dr. William Manlius Smith, of Syracuse, made a motion that all discussion of the paper lie over until the next meeting of the society.

The motion was lost, and the discussion was opened by Dr. H. D. Didama, of Syracuse. He stated that Dr. Mercer's paper was inconsistent, and was a good paper in favor of the old code. He then entered into a long argument in favor of the "old code," very much after the manner of the paper presented at the last meeting of the society.

Dr. I. N. Goff, of Cazenovia, who was present as a delegate from the Madison County Society, said that it was a great mystery to him how Dr. Didama could come to Cazenovia and consult with Dr. Bass, who is a homœopath. Dr. Didama had, to his positive knowledge, been to see Mr. E. S. Cord's child on Lincoln Street. The child had diptheria, and Dr. Bass was in
POOLEY: THROMBUS OF THE OLECRANON BURSA.

By J. H. POOLEY, M.D.,

PROFESSOR OF SURGERY IN THE TOLEDO MEDICAL COLLEGE.

On July 13, 1883, John Forney, a laboring man of middle age, applied to me on account of a swelling upon his right elbow. He stated that the swelling occurred suddenly, while he was at work digging a ditch. He struck his elbow against the side of the trench, but by no means violently, for it gave him no pain, did not interfere with work, and probably would not have been noticed at all, or even remembered, but for the subsequent swelling, which he noticed for the first time an hour or two afterward.

The swelling was directly over the olecranon bursa, very prominent, of about the size of a pigeon's egg, and of an oval shape. It was perfectly free from pain, tenderness, heat, or discoloration, and did not interfere with the use or movement of his arm. It was tense and fluctuating. I must confess that I was skeptical as to the man's account of its occurrence, and supposed it to be one of those chronic bursal enlargements not unfrequently met with in this situation, and which he had strangely overlooked until the slight blow called his attention to it; but he expressed himself as quite certain that this was not the case, but that it had made its first appearance at the time stated.

I punctured it with a small sharp-pointed bistoury, expecting to see the ordinary yellow glairy fluid spurt out, but, on the contrary, nothing appeared but some dark-colored blood, whereupon I opened it rather freely, and found the swelling mainly occupied by a dark, softish clot. This was squeezed out, and a warm-water dressing ordered. I saw no more of the man, but heard two weeks afterward that the cut, which had never given him any trouble or interfered with his daily work, was healed up.

We have here, then, a genuine case of thrombus or hematocoele of the olecranon bursa, an accident which I have never seen before, and of which I have never heard or read any account. The very slight blow which seems to have caused it is remarkable, the more so as the man appeared to be in good health, and presented no rigidity of the superficial arteries, areas, or other evidence of premature senility, all of which were carefully looked for.

Book Notices.

The contributors to this the third volume of this important work are Edmund Andrews, Richard Barwell, Edward Bellamy, P. S. Conner, John A. Lidell, M. Nicaise, and John A. Wyeth. The articles by Barwell, Bellamy, and Nicaise will at once attract attention from the well-known reputation of these foreign writers, while those of our own countrymen will not be found to suffer in comparison. The articles contained in this volume are the following: Injuries and Diseases of the Muscles, Tendons, and Fascia, by Conner; Injuries and Surgical Diseases of the Lymphatics, by Bellamy; Injuries of Blood-vessels, by Lidell; Surgical Diseases of the Vascular System, by Wyeth; Aneurysm, by Barwell; Injuries and Diseases of Nerves, by Nicaise; and Injuries of Joints, by Andrews.

The chapter on the muscles includes several subjects not usually given in general surgical works, such as hypertrophy and atrophy; granular, pigmented, fatty, and waxy degeneration; progressive muscular atrophy; and pseudo-hypertrophic paralysis. Each is briefly described, too briefly, in fact, as this subject, with that of the tendons, covers only twenty-five pages; but much that is valuable has been condensed into a small space. The chapter by Bellamy, on the lymphatics, although compressed into sixteen pages, is one of the best in the book. The five hundred pages which follow, and, with those on the diseases of the nerves, constitute the main body of the volume, are devoted to the vascular system, and are divided into three sections: Injuries of Blood-vessels, Surgical Diseases of the Vascular System, and Aneurysm. The first, by Lidell, is composed of what is usually found in text-books under this heading. All the injuries of all the arteries, with the treatment suitable for each case, are considered, and the cases given for illustration show the wide range of reading always manifested in the writings of this author. It is not a subject which admits of any originality, and the author has done all that could be expected in presenting it clearly, fully, and concisely. Wyeth, in the next article, on Surgical Diseases of the Vascular System, has done excellent work; and in handling arteritis, phlebitis, atheroma, thrombus, embolism, and vascular tumors, has contributed a great part of the value which the volume possesses as a whole. From Barwell we expect good work on the subject of aneurysm, and the reader will not be disappointed.
Without saying nearly as much as he might have said, he has covered the ground very thoroughly in fewer than one hundred and seventy-five pages, picking out the salient points in pathology, and in the treatment of each particular variety.

The idea ofdevoting a special chapter to the surgery of the nervous system in a work of this kind was an exceedingly good one, and Nicaise is a good man for the work. In the hundred pages devoted to it, he has dealt with contusions, concussion, and crushing of nerves; with wounds and their treatment; with the phenomena following injuries; with neuritis, neuralgia, tumors, and tetanus; and with the operations practiced upon nerves. In short, he has done what is seldom done in a work on general surgery. The last chapter, on Injuries of Joints, may be summed up in much the same words as the one on injuries of the blood-vessels—much that is good; little that is new.

If the excuse for publishing a new Surgery is the furnishing of new and valuable matter, there is enough of both in the volume to satisfy the purchaser; and for that part which is not new we can only say that it is fully as good as can be found elsewhere.

A Treatise on Therapeutics, comprising Materia Medica and Toxicology, with Special Reference to the Application of the Physiological Action of Drugs to Clinical Medicine. By H. C. Woon, M. D., Professor of Materia Medica and Therapeutics, and Clinical Professor of Diseases of the Nervous System, in the University of Pennsylvania, etc. Fifth edition, revised and enlarged. Philadelphia: J. B. Lippincott & Co., 1883. Pp. xii-17 to 740, inclusive. [Price, $6.60.]

In view of the limited time at the author's disposal for preparing this edition, but six months having elapsed since the issue of its predecessor, the reader should not feel impatient if he fails to find in it every therapeutical novelty that has figured in recent periodical literature. He may be sure that almost everything in the materia medica that has passed the period of probation is presented, and in a way that is in every respect satisfactory. As a matter of fact, too, the citations are many of them quite fresh, some being taken from publications brought out during the current year.

Dr. Wood's treatise holds a position by itself, being, in our opinion, the most philosophic work on the subject in the English language, while at the same time it is rich in those details of application that are most welcome to the practitioner.

In speaking of former editions of this work, we have taken occasion to specify the value of the odds and ends of information it furnishes. This edition has been adapted to the new pharmacopoeia, and many practical everyday matters, not readily to be found in more pretentious books, have been added. The work well deserves the success it has met with.

The "New Church Academy," which we take to be an organization connected with the Swedenborgian church, is what Dr. Ellis replies to, and not the journal known as "The Academy." It seems that this body has criticized a publication of the author's in which he maintained that various ancient words, all of which are expressed in English by the word wine, were of different signification, some of them referring to the fermented juice of the grape, and others to substances having nothing to do with fermentation. The practical interest of the discussion hinges on the question of whether the approving references to wine in the Scriptures really related to what we now term wine, or to something else, the author maintaining the latter view. No amount of research or reasoning seems to bring us appreciably nearer to a solution of this question, and we can only say that our author handles it dexterously and courteously. Incidentally, a good deal of matter is brought in bearing upon the chemistry of fermentation, and on this account the book is of some interest to medical men.

It is well known that the publishers of this brochure are manufacturing pharmacists, who have introduced, practically speaking, a great number of drugs of vegetable origin. The real value of many of these drugs is still far from settled. We think the publication under notice will go far toward facilitating the work of establishing the true status of the drugs it treats of, for it will save experimenters the labor of wasting through a great mass of literature. By stating the effects that many observers have imputed to the substances in question, it will show at once what it is that is to be proved or disproved. From this point of view, we think the publishers deserve well of the profession, and the work itself may properly enough be said to be made up of "working bulletins."

BOOKS AND PAMPHLETS RECEIVED.

The Operative Treatment of Hare-Lip. By James Whitson, M. D., etc., Surgeon to the Dispensary of Anderson's College, etc. [Reprint from the "Edinburgh Medical Journal."]
THE NEW YORK MEDICAL JOURNAL,

FRANK P. POSTER, M.D.

NEW YORK, SATURDAY, AUG 18, 1883.

THE ALLEGED PERSECUTION OF MEDICAL COLLEGES.

In our issue of June 16th we recorded the fact that the Governor of the State of New York had declined to sign a bill, passed by the Legislature, legalizing the organization of the United States Medical College and, as a consequence, the diplomas issued by the concern. We remarked at the time upon the sweeping character of the bill, and upon its injurious import. At that time a judgment rendered by the Special Term of the Supreme Court in April had declared against the legality of the college, and had enjoined the defendants in the action from further acting, or assuming to act, as an incorporated medical college; and the defendants had taken an appeal to the General Term. On Thursday of last week the decision of the General Term was rendered, in an opinion prepared by Justice Brady, affirming the judgment of the Special Term.

The defendants' counsel is understood to have said that he would take the case to the Court of Appeals, and to have proclaimed his confidence that it would there be settled to his clients' satisfaction. He is reported to have added that, as the case stood now, it was "simply a persecution," a number of young men, presumably the graduates of the college, being "thrown out of business" by the decision, by reason of their diplomas becoming null and void. Of course, the Court of Appeals, before which the case is expected to come up next winter, will see through the persecution plea, and there is nothing to be apprehended on that score in this particular case. The cry of persecution is so readily available as a cloak for all sorts of pernicious doings, however, so potent with the public, and so comforting a sop to the legislative conscience when it comes to the matter of trading votes, that it will be surprising indeed if it is not carried to the extreme in furtherance of more meddling with the processes of the courts on the part of the Legislature.

It will undoubtedly be urged, in behalf of this college and others of the same order, that proceedings are taken against them in the interest of non-sectarian medicine as opposed to the sects. The fact that there is no foundation for this allegation will be difficult to prove, although nothing is surer. The result may be, that the feeble protection now afforded the community by the Medical Practice Act will be taken away by the repeal of the act. In connection, therefore, both with this matter and with the scheme for the establishment of a State examining board, it is of the last importance that individual members of the medical profession should lose no opportunity of disabusing those with whom they come in contact, and especially persons having a voice in legislation, of the notion that the profession has any desire to make war upon the sects. The community should be given to understand clearly that we have no desire to oppose legal obstacles to the practice of homoeopathy, "eclecticism," or any other "system" of therapeutics, nor any idea of bringing persecution to bear upon the professed adherents of the sects, however persuaded we may be that their sectarian garments are put on for ad captandum purposes; but that what we are striving for is, that it shall be made impossible for incompetent men to practice medicine with the sanction of the State, no matter what their notions may be as to the propriety or the policy of practicing, or pretending to practice, under this or that dogma, or under no dogma. That this is the real feeling of the profession in the State of New York, there can be no question.

THE RECENT TRAGEDY AT THE NORRISTOWN LUNATIC ASYLUM.

It is not many months since, as we recorded at the time, the Rev. Heber Newton, having read a paper before the National Association for the Protection of the Insane, at its meeting in Philadelphia, in which he commented severely on the manner in which the insane were treated in lunatic asylums, was given to understand by a Philadelphia neurologist that he had brought his wares to the wrong market, for the insane were always treated well in Pennsylvania.

The latter statement was as irrelevant and uncalled for as could be imagined. It now seems likely to be shown to be untrue also. In our issue of July 21st we alluded to a brutal assault on a patient in the asylum at Norristown, by an attendant, and expressed our surprise that the asylum officials took no steps to secure the offender's arraignment before a court instead of simply dismissing him. The trustees of the asylum have lately been considering the conduct of the physicians in that regard, and we are glad to record that they seem to be of our way of thinking.

A wretch of an attendant, named Gaffey, pounded a patient, a Mr. Fiss, so brutally that the death of the latter, which took place soon afterward, seems clearly to have happened in consequence of the affair. Gaffey's punishment consisted in being "thrown out of business." He wandered about the town for a week or more, seeking employment—eager, no doubt, for an engagement to "tend an invalid." It is only during the current week that he has been apprehended.

Not the least remarkable feature of the matter is the cool impudence with which one of the physicians of the asylum, having been brought before the trustees for examination, jauntily justified his own conduct. He found Mr. Fiss with blood flowing from his face, and discovered that his lower jaw was broken on both sides; yet, when asked if he did not think he ought to have had Gaffey arrested, he replied: "Well, I felt he wouldn't run away if he was wanted. I didn't consider the matter of much importance."

The affair is indeed so outrageous that the superintendent of an asylum in Morristown, N. J., has thought it prudent to call attention in the newspapers to the fact that Morristown is not
Norristown. Possibly Mr. Newton’s paper in print will not receive such cavalier treatment as it got when read before the association.

AN INTERNATIONAL ASPECT OF THE FOOT AND MOUTH DISEASE.

A resolution having passed the British House of Commons opposing the importation of cattle from any country in which the foot and mouth disease prevails, a measure obviously and almost confessedly aimed at the American cattle trade, the Acting Secretary of the United States Treasury has issued a circular to Collectors of Customs and others, embodying a report by the Treasury Cattle Commission, signed by two gentlemen of acknowledged authority in veterinary medicine, and of unquestioned carefulness as observers, in which some facts are made public that can scarcely heighten our sense of the ingenuousness of the British Government.

The Commissioners state that, after a most extended and almost exhaustive inquiry, they have not found a trace of the foot and mouth disease, except in herds just landed from Great Britain, and their investigation has covered all the lines of cattle traffic, from the great rendezvous at Kansas City, Council Bluffs, and Omaha to the Atlantic seaboard. In view of the unmistakable features of the disease, its extreme contagiousness, the well-nigh universal susceptibility of domestic animals to the infection, the remarkably brief duration of its period of incubation, and the fact that so great a dread of the disease pervades the agricultural community that every farmer’s club in the line of the trade is constantly on the lookout for the first sign of an outbreak, the Commissioners argue that it can not have existed in the country during the period covered by their investigation and not have come to their knowledge. It certainly seems as if this inference were unassailable.

The report then goes on to the consideration of certain occurrences which, the Commissioners suppose, must have been made the pretext for the action taken by the British authorities, namely, the landing of American cattle in Great Britain suffering from foot and mouth disease contracted on board infected British ships. Two instances are given in which British steamships landed infected Channel Island cattle at our ports—one being the case of the France, of the National Line, that landed such a cargo at New York two years ago, and the other that of the Nessmore, that did the same thing at Baltimore last March. Both of these vessels went through an attempt at disinfection, and then shipped healthy American cattle for the home voyage—the cattle, of course, contracting the disease on board. In regard to restrictive measures, therefore, it seems that this country would be far more justified in resorting to them than Great Britain.

THE CHOLERA DEBATE AT THE PARIS ACADEMY.

For about the twentieth time, as one of the speakers remarked, M. Jules Guérin recently regaled the Paris Académie de Médecine with the stock of data on which he founds his belief that cholera is incapable of transportation, and that there fore there is no sense in trying to fight it by quarantine. The occasion was a discussion of a paper that had been read before the academy by M. Fauvel, on the cholera in Egypt.

M. Guérin is a vigorous and somewhat irrepressible disputant, as will readily be called to mind by those who remember his pertinacious efforts to smother the minimal vaccination movement in ridicule when M. Depaul’s projet de rapport was under discussion by the same body nearly twenty years ago. But he seems to be meeting with no more substantial success now than then. In truth, this fact seems to have dawned upon him, for at one of the sessions he complained of what he thought had been said concerning his remarks at a previous meeting—terming the criticism censorious. Being assured by the president, M. Hardy, that nothing improper had been said of him, with a hint that he might have taken it for granted that anything of that sort would not be allowed, M. Guérin was pacified.

M. Guérin allows that cholera is infectious, but maintains that it is not transportable—that the great epidemics that have overrun Europe have not been of Indian origin, but have arisen from local causes. In the course of his remarks in the discussion alluded to, he repeated his expressions of confidence in the home-sanitation policy of the English, and took occasion incidentally to deliver himself of a panegyric on the English sanitary officials in India, speaking of them as “the best in the world.”

M. Guérin’s data were very thoroughly picked to pieces in the discussion, but he seems to have drawn a satisfactory amount of solace from the reflection that in this matter he was in accord with the greatest masters of science, from Hippocrates down, which is, of course, better than to have coped successfully with his nineteenth-century opponents.

SMALL-POX AND QUACKERY IN ST. PAUL.

In a recent number of the “Northwestern Lancet,” of St. Paul, Minn., we find an account of the circumstances attending a rather remarkable outbreak of small-pox observed in that city last month. It seems that a child, nine years old, that had been in poor health for some time, was put under the care of a female practitioner in St. Paul who styles herself a “magnetic healer.” At that time the child had been seized with pains in the back and the limbs, which the “healer” diagnosed as “sciatic rheumatism.” Soon after this the child was found to have fever, and a rash made its appearance—“an eruption of the blood,” said the “healer,” caused by the “strong medicine” employed before the patient had come under her care. She gave an encouraging prognosis, and persevered with her treatment. Before long, the family and the neighbors betook themselves of small-pox, and asked the “healer” if it might not be that disease that the child was suffering from. On being asked this question, the woman professed to consult the spirit of a doctor who, she said, had been dead several hundred years. The spirit having assured her emphatically that her patient’s sickness was not small-pox, she informed the family to that effect, and repeated her cheerful prognosis. Nevertheless, the child grew worse steadily, the family became dissatisfied, and at last the
father called in a regular physician, who pronounced the case one of confluent small-pox rapidly approaching a fatal termination.

The scene of these occurrences was a large boarding-house, and quite a number of persons were exposed to the disease, the result being, that ten persons were infected, three of whom died. We congratulate the people of Minnesota upon the prospect that their new law regulating the practice of medicine, which is to go into effect in the course of a few months, will put a stop to the mummery that makes such incidents possible; and we commend the moral to be drawn from the story to the attention of those who think that nobody ought to be prevented from practicing medicine.

MINOR PARAGRAPHS.

THE SANITARY COUNCIL OF THE MISSISSIPPI VALLEY.

It is much to be regretted that a misunderstanding has arisen between this body and the Louisiana State Board of Health, both of which we believe to be actuated by genuine devotion to the public health. We have received a communication on the subject from the secretary of the council, of which, for lack of space, we are obliged to postpone the publication.

THE FOOT AND MOUTH DISEASE.

The British Government, in pursuance of its policy of forbidding the importation of cattle from countries where the foot and mouth disease prevails, is reported to have under consideration measures looking to a prohibition of the landing of cattle from the United States. It is stated at the Treasury Department, however, that there is really no prevalence of the disease in this country, as has been shown conclusively by an investigation, and that steps will be taken to represent the matter in its true light to the British Government.

A RAG QUARANTINE IN BOSTON HARBOR.

The Boston Board of Health has a quantity of Egyptian rags stored on Gallup's Island, under canvas. It is proposed to build a warehouse and wharf on the island, for the storage of goods supposed to be infected. It is said, however, that the Government will oppose the project, on the ground that the goods will endanger its employees who are building a sea wall on the west side of the island. But it is argued, on the other hand, that the Government can not properly oppose the scheme, unless it considers the wharf, which it is designed to build in fifty feet of water, an obstruction to navigation.

LEPROSY IN NEW BRUNSWICK.

The newspapers are making the most of a recent visit by Dr. George H. Fox and several other physicians of New York to the province of New Brunswick, for the purpose of investigating a number of cases of leprosy. It is not at all likely that these gentlemen constituted a "commission," as some of the papers say, but it is quite probable that, if Dr. Fox observed anything noteworthy, he will lay it before the New York Dermatological Society.

CONTAMINATION OF THE CHICAGO DRINKING-WATER.

We learn from the "Sanitary News" of Chicago, that the Chicago River is so contaminated with sewage that, in the opinion of a committee of the Citizens' Association, it can be called nothing else than an "abominable sewer." The foul contents of the North Branch are pumped into the lake, and drift out toward the water-works crib, thus contaminating the supply of drinking-water for the city. The committee referred to have made the following recommendations: 1. That the south fork of the South Branch should be purged of its impurities by the introduction of a canal or conduit from the lake along or near Thirty-ninth Street, or by such conduit from near that street to the present pumps at Bridgeport. This should be done without delay. 2. That the introduction of water from the Des Plaines River should be stopped, as far as can be, by the closing of the upper or southern end of the Ogden ditch. 3. That all city sewers should be made to empty into the river, and not into slips or cuttings, nor into the lake. 4. That the Fullerton Avenue pumps should not, under any circumstances, pump toward the lake. The clear water of the lake should always be added to the southward current or the upper or northern part of the Chicago River as it passes the works, and the whole sent forward to the Bridgeport pumping-works. 5. That the Bridgeport pump should be operated to the extent of sixty thousand cubic feet a minute, at all times when there is an observance of unclear water in the river, or when it is necessary to keep the canal-water pure, in accordance with existing State laws.

THE ENTRANCE EXAMINATION FOR THE UNIVERSITY OF PENNSYLVANIA.

It will be seen from our advertising columns that the faculty of the Medical Department of the University of Pennsylvania have made arrangements by which the preliminary examination in English composition and elementary physics, required of candidates who do not hold a college degree or are unable to show an equivalent evidence of proper academic instruction, may be passed in any one of ten different cities in various parts of the country. The faculty are to be commended for having taken such pains to enable young men desirous of matriculating at the University to save the trouble and expense of what might prove a useless journey to Philadelphia.

A PARTIAL QUARANTINE OF CARGOES.

The Health Officer of the Port of New York is said to have stated lately, in a letter read at a meeting of the directors of the Maritime Association, that, if cargo from non-infected ports was well isolated from that taken on board the same vessel at infected ports, and if the history of the vessel in respect to infectious or contagious disease was unobjectionable, the cargo from infected ports only would be required to be discharged in quarantine; and that, by such disposition of the cargo from objectionable ports as would enable the Health Officer to feel assured that the portion of the vessel occupied by such cargo could be thoroughly cleansed and disinfected, considerable time and expense might be saved to importers.

We trust that nothing will happen to show that the Health Officer has been unwise in this matter, but there seems reason to fear serious consequences from the course referred to.

THE AMERICAN VETERINARY HOSPITAL.

We learn from the Eighth Annual Report of this excellent institution that during the year ending February 28, 1888, 2,679 animals were brought to the hospital for advice or treatment, of which 977 were attended gratuitously. The hospital, which is a department of the American Veterinary College, is situated at No. 141 West Fifty-fourth Street. The medical
staff consists of A. Liantard, M. D., H. F. R. C. V. S., Chief Surgeon; W. J. Coutts, M. D., D. V. S., Assistant Surgeon; J. S. Kemp, Jr., D. V. S., and F. Saunders, D. V. S., House Surgeons. According to the Report, the hospital is much in need of enlargement, many animals having been turned away during the year for lack of room.

AN ATTEMPT TO DISCIPLINE VIRCHOW.

Although it is nobody's business but his own that Professor Virchow has seen fit to allow his name to be used as having recommended a proprietary preparation known as Helvetian pills, a German medical society has pointed out to him the sinfulness of his ways. At last accounts not much of an impression seemed to have been made upon him, however.

THE "MEDICAL HERALD" ON PROFESSOR LEEDS.

The "Medical Herald," of Louisville, quotes the following statement from a lecture by Professor Leeds, of Hoboken, published in our issue of April 28th: "Savory and Moore's food has about thirty-six per cent. of starch, and twenty per cent. of grape and ninety-nine per cent. of cane-sugar, besides nearly ten per cent. of albuminoids." On the strength of this evident error, our contemporary indulges in some humorous remarks, but it omits to state that the passage it quotes from this journal was accompanied by a reference to a table of analyses that had preceded it, in which table the proportion of cane-sugar was correctly given as 9.98 per cent. Since the "Herald" overlooks this plain evidence that the error in question was not Professor Leeds's but, the proof-reader's, we can only infer that printers' errors are unknown in the office of that publication—an inference that we should not otherwise have drawn.

AN ENGLISH ABORTIONIST.

In one of our London contemporaries we find a recital which goes to show that it is not alone in this country that professed abortionists ply their wretched trade. A servant girl became pregnant by her master, and the latter took her to a dog-dealer, who seems to have formerly been a medical student and to have been in partnership with a medical practitioner, a diploma of the Royal College of Surgeons, in the practitioner's name, having been found in his possession. The dog-dealer performed an operation on the girl, cheering her with the assurance that he had been successful in ninety cases in a hundred. After this the girl went to her home, and, becoming dangerously sick, informed her parents of what had taken place. Both her master and the dog-dealer were brought to trial and convicted, the former being sentenced to seven, and the latter to nine years of penal servitude. At the trial there was medical evidence to corroborate the girl's testimony, and the judge is said to have expressed his belief that the dog-dealer was a professed abortionist, and that his estimate of his success in the practice was probably correct. The singular point about the matter is, that a dog-dealer should have ever been "in partnership" with a medical man practicing under the diploma of the Royal College of Surgeons.

MISTAKEN DIAGNOSES OF SMALL-POX.

The "Medical Chronicle," of Baltimore, quotes the following from the "New England Medical Monthly": "In Germantown, Pa., recently a lady was sent to the pest-house for small-pox, when it was found that she only had the measles. While in the hospital she took varioloid. Five similar cases were reported in Baltimore during one week. They must have curious health authorities in both of these places."

The "Chronicle" adds this guarded denial: "So far as Baltimore is concerned, we have authority for stating that it is not true that 'five similar cases' of mistaken diagnosis occurred 'during one week.'"

A NEW SERIES OF EMETIC SALTS.

At a recent meeting of the Paris Académie des Sciences, a brief note was read from M. de Klein on certain emetic salts formed from muscle acid, corresponding in constitution with like salts of tartaric acid. The salts chiefly referred to were borico-potassio, borico-sodic, ammonico-antimonium, and ammonico-antimonial nucates.

REQUESTS TO HOSPITALS AND THE DELIRIUM OF PERSECUTION.

In a recent clinical lecture on the variety of insanity termed the delirium of persecution, M. Logrand du Sainte gives his decided conviction that most of the so-called philanthropists who bequeath their property to hospitals, educational institutions, and the like, are really the victims of this sort of mental alienation. Esotogical and avareous during their life, he says, they pass for benefactors of humanity after they are dead.

THE EFFECT OF MENTAL WORK ON HEALTH.

While there may be some sense in deprecating what has been called the "forcing system" in schools, from a sanitary point, we have never been convinced that intellectual work was often the real cause of the physical ills so freely imputed to it. We are glad to observe, therefore, that Sir Lyon Playfair has recently cited facts before the British House of Commons that positively disprove the theory alluded to. It even appears that an improvement in the health of English youth has followed the enforcement of the Education Act.

NEWS ITEMS.

A MEDICAL PUBLICATION DISPUTE.—On Tuesday Judge Mitchell, of Philadelphia, granted a preliminary injunction restraining Samuel M. Miller, M. D., from continuing the publication of a book which he is issuing under the title, "An Epitome of Medicine, Surgery, and Obstetrics, including Nervous Diseases and the Diseases of Women and Children, by Alfred Stillé, Professor of the Theory and Practice of Medicine in the University of Pennsylvania, D. Hayes Agnew, Professor of Surgery and Clinical Surgery, and R. A. F. Penrose, Professor of Obstetrics." According to the Philadelphia "Press," Professor Stillé and Professor Agnew, upon whose petitions, supported by affidavits, the injunction was issued, declare that this publication is without their authority, and consists only of an incomplete and careless rehash of the oral lectures which they have been delivering to the students at the University, to which the publisher has contributed nothing but the summarization and the errors. They further allege that the publication is calculated to injure them, both professionally and financially.

YELLOW FEVER continues its ravages in Cuba, and several cases are reported to have occurred in Panama during the past few weeks. In Mexico it is epidemic in several towns besides Vera Cruz. Except for the New York health officers' remarkable leniency in the matter of detaining cargoes, the precautions taken at our chief ports seem to be ample for the protection of the country. A steamer has been stationed off the capes of the Chesapeake, to intercept and examine vessels from infected ports.
CHOLERA is still causing a heavy mortality in several Egyptian towns, but it has not thus far passed the limits of the country, and is evidently on the decline. It is said to be prevailing in Atheen. The San Francisco Board of Health has declares all Asiatic ports infected, and will maintain a rigid quarantine. The German Government has organized an expedition to Egypt, to investigate the disease now prevailing there.

The Singular Death of a Physician.—A story is going the rounds of the newspapers to the effect that a young physician of Chicago, Dr. Rex, lately died of "facial carbuncle," having diagnosticated his own case, and foretold his death, while yet there were no symptoms of any illness, simply from the appearance of the root of a hair which he had pulled out from his moustache, at a point where a pimple had appeared.

The Duty on Sulphate of Cinchonidine.—An uncertainty has arisen about a point in the interpretation of the new tariff on this alkaloid and its salts. The alkaloid itself is on the free list, but the tarif does not mention its salts. The importers contend that both were intended to be free, while the makers of quinine assert that the sulphate is subject to the old duty of twenty-five per cent.

Small-pox is reported to be making great havoc among the Indians in Manitoba, and is prevalent at several points in Mexico.

Harvard Medical School.—Dr. Calvin Ellis has resigned the position of dean of the faculty.

The Austrian System of School Hygiene is to be studied by a French commissioner, Dr. Javal.

Professor G. M. Humphrey, F. R. S., will preside over the Congress of the Sanitary Institute of Great Britain, to be held in Glasgow in September.

Obituary Notes.

Jacob S. Mosher, M. D., of Albany.—Dr. Mosher died suddenly at his residence in Albany on Monday, the 13th inst., at the age of forty-nine. He was born in Coeymans, N. Y., March 19, 1834. He received his collegiate education at Rutgers College, and in December, 1858, graduated from the Albany Medical College. In 1864 he entered the United States Service as a volunteer surgeon, serving in the army of the Potomac before Petersburg. He was subsequently made Assistant Medical Director for the State of New York, on duty in Washington. From 1863 to 1870 he was Deputy Health Officer of the Port of New York, and from 1869 to 1873, inclusive, was Surgeon-General of the State of New York. Dr. Mosher was a member of the Medical Society of the State of New York, and of the New York Neurological Society, and a Fellow of the New York Academy of Medicine. For several years he was Professor of Chemistry and Medical Jurisprudence, and also Registrar and Librarian in the Albany Medical College. He was well known and highly esteemed for his social qualities and literary attainments.

Josph C. Curtis, M. D.—Dr. Curtis died suddenly in London on the 1st instant. He was born in Wethersfield, Conn., April 30, 1816, and entered Yale College in 1836. In 1843 he graduated from the Jefferson Medical College. In 1845 he settled in Lowell, Mass., from which city he moved to Boston in 1849. At the outbreak of the war of the rebellion Dr. Curtis was commissioned brigade surgeon by President Lincoln, and served in the field and in hospitals until 1865, when he took up his residence in Knoxville, Tenn. In 1872 he crossed the Rocky Mountains as surgeon, microscopist, and naturalist to the United States Geological Survey, and in 1873 he was appointed chief medical officer to the United States Indian Service. Dr. Curtis was a member of several medical and scientific societies, and was much interested in matters relating to sanitary science, upon which subject he wrote a number of papers, and made several reports to the Legislature of Massachusetts.

Alexander Patrick Stewart, M. D., F. R. C. P., of London.—Dr. Stewart, a Scotchman by birth, but for many years resident in London, died on the 17th ult., at the age of seventy. He made some important contributions to medical literature, and was among the earliest and most enthusiastic of the promoters of the British Medical Association. Our London contemporaries speak fervently of the generous and amiable qualities of the deceased gentleman.

M. Paul Dubois, of Paris.—We learn from the "Progrès médical" that M. Dubois died on the 25th of July, at the age of forty-two. He obtained his medical degree in 1868, his graduation thesis, étude sur quelques points de l'atlas locomotrices progressive, inspired by M. Charcot, being remarkable for its excellence. M. Dubois served as a volunteer surgeon in the Franco-Prussian War, and on many occasions displayed a conscientious devotion to the welfare of his country. In recognition of his services, he was thrice elected a member of the Municipal Council of Paris.

M. Van Hevel, of Belgium.—The death of M. Van Hevel is announced by the Belgian journals. He was known as the inventor of an exceedingly ingenious forceps-saw for laryngotomy and of an elaborate pelvimeter. He died at an advanced age.

Proceedings of Societies.

College of Physicians of Philadelphia.

Meeting of April 4, 1883.

Does Excision of the Larynx Tend to the Prolongation of Life?—Dr. J. Solis Cohen, Honorary Professor of Laryngology in the Jefferson Medical College, read the following paper:

That complete laryngectomy can be performed without sacrifice of life, there is now accumulative evidence. That every operation involving the removal of the larynx imperils the immediate existence of the patient, the records of the procedure abundantly attest. That a very large proportion of the subjects operated upon, say nearly fifty per cent. of them, succumb within so brief a period that their deaths may be justly attributed to the operation, an examination into its statistics renders only too obvious. The writer owns to a prejudice against the operation; he has never witnessed a laryngectomy, nor seen a patient upon whom it had been performed. It may seem rather an assumption on his part, therefore, to criticise an operation of the technical procedure and after-management of which he is practically ignorant.

Let us consult the statistics of the operation, and contrast the average life of those who have been subjected to it with the average life of patients in similar condition, intrusted to palliative treatment. I have before me, as I write, more or less detailed records of sixty-five operations of complete "extirpation of the larynx," as it is termed. There are a number of partial excisions, which have not been brought into the subjoined table because the partial operation is not included in the scope of this paper.

</table>
Of these sixty-five complete operations, four were performed in non-malignant cases; one for cicatricial syphilitic stenosis, with death "some weeks after from pneumonia" (Case 1) [Watson]; one for necrosis, the case terminating fatally by a marasmus five days after the operation (Case 22) [Rubio]; one for polypi of the larynx (Case 64) [Ruggi]; and one for papilloma of the larynx (Case 65) [McLeod].

Of the sixty-one operations remaining in this list, five were performed for sarcoma; in two of which the results were so remarkably exceptional that attention should be especially directed to them.

I. Bottini, of Turin, on February 6, 1873, removed the entire larynx from a male subject twenty-four years of age, with a laryngeal sarcoma, partly round-celled, partly spindle-celled. Notwithstanding copious hemorrhage and severe erysipelas, the patient recovered. He was reported well in August, 1881, or more than six years after the operation, and I have seen no notice of his death. He had been performing the duties of a postman, and walking eight miles a day. This is the most successful case on record.

II. Caselli, of Reggio-Emilia, on September 29, 1879, removed the larynx, pharynx, base of the tongue, soft palate and tonsils, from a female subject nineteen years of age, for a sarcoma of the larynx, pharynx, palate, and base of tongue. The patient was reported well in August, 1881, practically two years after the operation, and I have seen no notice of her death. This is the second best case on record.

The remaining three patients operated upon for sarcoma died at the periods of seven, fifteen, and seventeen and a half months, respectively.

The history of the remaining fifty-six operations presents a much more gloomy account. They were all for carcinoma, if we may include under that head Schede's case (56) of "can-croid."

Let me read the list of deaths as far as reported:

To this list may be added the cases of:

- Margary, Case 51, in which recurrence was reported at 3 months.
- Kocher, " 58, " 6 " 7 "
- In the following cases neither death nor recurrence has been reported:
  1. Fouil, Case 43, alive 5 weeks after operation.
  2. Czerny, " 43, " 6 "
  3. Schede, " 56, artificial larynx adjusted 2 months after operation.
  4. Mayol, " 68, no recurrence 3 months after operation.
  5. Von Bergmann, " 60, alive "some" 
  7. Whitehead, " 59, "no recurrence"; alive 8 months after operation.
  8. Winiwarter, " 41, "no recurrence"; alive 11 months after operation.
  9. Gussenbauer, " 52, well 14 months after operation.
  10. Kocher, " 46, no recurrence 16 months after operation.
  11. Thieresch, " 33, well 17 months after operation.
  12. Thieresch, " 32, " 18 "
  13. Gussenbauer, " 47, " 19 "
  14. Hahn, " 35, " 2 years "

Of the forty reported deaths, seventeen, or forty-two and a half per cent., occurred within eight days, and five more succumbed within the second period of eight days.

The danger during the first few days is from shock and from pneumonia. Very few have perished from direct shock, very many from pneumonia. The pneumonia has been attributed generally to the ingress of blood, aliments, and septic materials into the air-passages; but, if I may form an opinion from what I have witnessed in many other operations upon the neck, there is a certain amount of risk of pneumonia in all surgical interferences in the cervical region, even when the air-passage is not opened. Thus, I have seen it follow extirpation of the thyroid gland, extirpation of cervical neoplasms, and even exploratory incision into the region. It may be that the reduction of temperature to which the pneumogastric nerve is subjected leads to pneumonia, and that the manipulations within the wound render it especially sensitive. When we reflect that the majority of these operations of laryngectomy consume from one to three hours in their performance, we can fairly presume that the pneumogastric nerve is subjected to sufficient ordeal to excite an early pneumonia, quite independently of access of foreign matter to the lungs—a sequel of the operation against which every available precaution is taken.

The danger from pneumonia does not seem to exist longer than two weeks, for we have but one record of death from this cause after the sixteenth day, and that from "croupous pneumonia." (Case 10), at the end of three months. This important fortnight safely passed, the life of the patient appears comparatively secure up to the fourth month. At the fourth month, death begins to be imminent from recurrence, and we have, in our table, three at four months; one, and possibly several, within five months; two at six months; one at seven months; three at nine months; and one at fifteen months. One death from recurrence (Case 11) is reported at two months after operation. Nine patients are reported living at seven, eight, eleven, fourteen, sixteen, seventeen, eighteen, nineteen, and twenty-four months, respectively. Thus forty-two and one half per cent. of the forty cases, recorded as terminating fatally, or more than thirty per cent. of the entire number of patients operated upon for carcinoma, perished within eight days; and, at the end of six months, thirty-five of the forty were dead, or eighty-seven and one half per cent.: making sixty-two and one half per cent. of the entire fifty-six operations for carcinoma; with great probability of a still higher percentage had all the deaths been reported.
Let us contrast this record with the average life of carcinoma of the larynx not subjected to the radical operation of laryngectomy. Of a number of patients with carcinoma of the larynx under my own care, who agreed to submit to exsection of the larynx I so determine, and in whom I performed tracheotomy in preference, one lived six months, two lived seven months, one lived thirteen months, and one eighteen months, respectively, after the tracheotomy.

If laryngectomy been practiced in these five cases, with equal tenure of existence, the result would have been accredited to the radical procedure. Had the operation been performed, one life might possibly have been prolonged; the majority, however, would probably have been shortened. At the period at the end of which eighty-seven and a half per cent. of the recorded deaths after laryngectomy had occurred, i.e., six months, all my tracheotomized patients were living; and but two of the entire number of fifty-six in whom excision was performed for carcinoma outlived the longest-lived instance in my tracheotomized list. It is not improbable that a complete series of collated statistics would present a far better exhibit for the cases merely subjected to tracheotomy and palliative procedure. It is generally believed that the natural history of carcinoma of the larynx comprises an average existence of about two years and a half; tracheotomy becoming requisite at a period varying from nine to eighteen months, according as the disease is wholly intra-laryngeal or more parietal.

In laryngectomy, the initial shock is severe, and sure to carry off a large percentage of patients by collapse or by pneumonia. A certain number of lives are sacrificed; and the condition of the survivors, with their artificial substitutes for the larynx, is often described as pitiable in the extreme.

In tracheotomy, there is little shock, very slight danger of pneumonia, and much less risk of septic infection. Life is not likely to be sacrificed in any instance; and existence is much more comfortable after the operation than after laryngectomy.

For these reasons, excision of the larynx for carcinoma does not, in my opinion, tend to the prolongation of life; for the prolonged existence of a very few seems purchasable only at the sacrifice of the remnants of existence of many others. The greatest good to the greatest number appears better secured by dependence on the palliative operation of tracheotomy.

OBSTETRICAL SOCIETY OF PHILADELPHIA.

A stated meeting was held May 3, 1883, the President, R. A. Cleemann, M. D., in the chair.

Three stubborn cases of vesico-vaginal fistula successfully treated after the operation without the use of the catheter.—Dr. W. Goodell related the histories. The first patient, after a non-instrumental labor lasting from a Tuesday evening, when the membranes broke, to a Friday night, found that her urine dribbled away immediately after the birth of the child. The fistula was situated so close to the cervix as to implicate it, and was quite large. Sixteen months after the accident she was operated on by a distinguished surgeon, whose success in uro-genital fistula was very great. He turned the cervix into the bladder and successfully closed up all the rent save a small portion of it. On this fistula he operated three times without any union whatever. In each instance the urine dribbled away before the stitches were removed, and on two occasions an alarming hemorrhage came per vaginam. This information Dr. Goodell obtained from the surgeon himself.

Early in 1877 Dr. Goodell operated on her at the Hospital of the University of Pennsylvania, and put in Sim's self-retaining catheter. Eight sutures were needed to close the opening. The next day a hemorrhage from the bladder, possibly mesural, took place and lasted several days. A fever also set in which gave some alarm. When the stitches were removed, very little union was found to have taken place. Four months later, Dr. Goodell operated for the second time, and, thinking that the vesical hemorrhage in the preceding operation was caused by the irritation of the self-retaining catheter, he treated her without one. The first twenty-four hours her urine was drawn off every four hours, but afterward was allowed to pass itself. No hemorrhage occurred, and perfect union took place.

The second case was also one of tedious labor in which the forceps was not used. The fistula, at first, was a very large one, and was most skillfully closed by an excellent surgeon. A very small fistula, however, remained at each angle of the wound. These defied repeated operations on his part, and the case finally drifted into Dr. Goodell's hands. Twice the latter operated at his private hospital on these fistulae, using the Goodman self-retaining catheter, but each time vesical and uterine tenesmus set in and the result was a failure. Both fistulae were then burned with the actual cautery and one of them closed up, but the larger one resisted this treatment, as well as that by nitric acid. He then operated upon it a month ago for the third time, dispensing with the use of the catheter. The lady was instructed to pass her water before the desire was urgent. Neither vesical nor uterine tenesmus occurred. The stitches were left in for fourteen days, and union was complete. The third case was the result of a short labor, and the cause of the fistula was obscure, as the lady was attended by a midwife, who pulled and tugged away at something after the birth of the child. The late Dr. H. Lenox Hodge had operated five times upon it, closing all but a small fistula which lay at the junction of the neck of the bladder with the urethra. Dr. Goodell closed this fistula at the Hospital of the University, three weeks ago, with eight stitches, and, fearing that the catheter would interfere with the union, dispensed wholly with it. The success was complete.

From these cases, and from others which he had met with, Dr. Goodell was led to think that the catheter might, as a source of irritation, oftener be dispensed with very advantageously in the treatment of these fistulae. He cited the practice of the late Dr. Simon, of Heidelberg, who was a very successful operator, and yet rarely resorted to its use. He also called attention to the fact that in these cases, and in the very great majority of the cases he had met with, the forceps had not been resorted to, showing that it was not the use of that instrument, but its neglect, or the delay in its use, that caused the mischief. In fact, he could not recall a case in which the lesion could be attributed to instrumental delivery. In the general experience of surgeons, very small vesico-vaginal fistulae were harder to cure than moderate sized ones. One reason for this was the fact they were usually found in sites difficult to reach; and another, that the operator was unwilling to enlarge the small opening by bold incisions, and failed from too small a denuded surface. Including the one previously referred to, he had closed two of them by means of the actual cautery.

Dr. Albert H. Smith remarked that these cases were of great interest. He had been taken by surprise when Dr. Simon announced his plan of treatment without the catheter, as he had been afraid of the strain on the stiches resulting from the accumulation of urine in the bladder. The presence of the self-retaining catheter most necessarily be a source of irritation and vesical tenesmus. The small holes in its bulb might become occluded by mucus or clot, and then it would act as a plug instead of a drain. In those cases in which the loss of substance in the vesico-vaginal septum had been very great, and the mucous surface of the bladder had been palpated into the vagina, the ca-
capacity of the bladder became small, and it must be emptied frequently or the tension on the stitches would be too great.

He had been gradually led to the conclusion that it would be better not to use the catheter after tracheorrhaphy and perineorrhaphy, unless called for by special circumstances. There were cases in which, in consequence of mental influence, or the effect of position, the patient could not pass her water for weeks after labor in which no injury or long or undue pressure had occurred.

Dr. R. P. Harris had recently operated for the restoration of a very long perineum; the last stitch was almost on a line with the orifice of the urethra, and the nurse was not able to introduce the catheter. He placed the patient in a sitting position to pass her water, and used a male catheter, tied on the tube of a Davidson syringe, to wash out the vagina.

Dr. Goodell was by no means a convert to treatment in this class of cases without the employment of the catheter. He had been too successful with it. He preferred the Goodman self-retaining instrument; but he always made certain that it did not impinge on the wound. He had recognized the influence of mind and of position on the ability to pass water, and he thought the use of ergot, so general before the third stage of labor, was one cause of the difficulty, as it was quite possible that it might cause a spasm of the urethral constricting fibers. He would like to dispense with the use of both catheter and syringe after perineorrhaphy, as he had found injuries to the anterior angle of the wound by the syringe and the fingers of the nurse while introducing the catheter. He had been in the habit of putting one stitch through the sound skin, above the denuded surfaces, to prevent this injury. In one case, recently, the Goodman catheter slipped out twenty-four hours after perineorrhaphy, and he did not replace it, the wound healing. He always used the catheter after tracheorrhaphy.

Two Ovarian Tumors, One of them of Doubtful Character.—The specimens were shown by Dr. Goodell. The one of doubtful character was removed from an unmarried woman, aged twenty-seven, who had not menstruated for over a year. It was first discovered nine years ago, but gave no trouble until two years and a half ago, when ascites set in. She had been tapped fourteen times when Dr. Goodell first saw her. She was very thin, pale, and so weak as to keep her bed. He recognized a hard tumor floating in the ascitic fluid, giving the feeling of ballottement, and diagnosed it as either a solid ovarian tumor or a pedunculated fibroid.

On the 16th of last April he removed it at the University Hospital, and found it to be a hard, solid, nodular tumor of the right ovary, with evidences of papillomatous degeneration. It had merely omental adhesions, and had a long, slender pedicle twisted many times on its axis. It was evident that the ascitic fluid was secreted directly from the tumor, and did not come from pressure on abdominal veins, or from irritation of the peritoneum.

The other cyst was removed also at the Hospital of the University, and on the same day, from a married woman, aged twenty-six, who noticed it two months after her marriage, and about four months ago. The cyst was as large as the adult head, and was apparently attached to the womb, which was drawn upward and gave a measurement of four inches. It was operated on early, because it caused great vesical disturbance. The lower portion of the cyst was found enveloped in the broad ligament close up to the womb, and had to be excised. It was this condition that gave the symptoms of uterine attachment. The cyst was that of the left ovary; but, as the right ovary also presented tokens of degeneration, it was also removed. Both women recovered promptly, although the first one had, on the third day, a severe attack of mumps, which appeared to be prevailing in this city as an epidemic. The ascitic fluid, which was straw-colored and syrupy, was not examined microscopically.

Dr. M. O'Hara wished to know how Dr. Goodell could decide quickly between mumps and septic parotitis. He also spoke of the reflex action of the sexual organs as shown by the frequent occurrence of salivation during pregnancy. In a recent case of cancer of the cervix, the first symptom observed was excessive secretion of saliva.

Dr. Albert H. Smith remarked that mumps was a very interesting and very perplexing disease. He had seen cases of extension of the disease, without retrogression, in adult women, to mastitis and oophoritis, the swelling of the parotid gland being rapidly followed by the involvement of the sexual glands, the inflammation of the ovaries being accompanied by local peritonitis. A singular question was raised by the case of a young man who went to Florida directly after marriage, and, on the return trip by sea, experienced a severe attack of mumps. It was complicated by orchitis, the inflammation being of high grade, with great increase of temperature and rapid pulse. No atrophy of the testicles had occurred, but the monon had been sterile, and there was no known fault on the part of the wife. The semen had not been examined microscopically to ascertain the presence of spermatozoide. The mastitis accompanying mumps had never, in Dr. Smith's experience, run into suppuration, but was accompanied by fibrous action of a higher grade. He had seen the ovary the original point of attack, the inflammation of the mammary gland being later. It was a marvel of pathology that this disease, which affected in childhood the salivary glands only, should, in adult life, affect the sexual glands also. He had never seen a case of atrophy of the testicles following mumps.

Dr. Goodell recognized mumps in this case by his experience in two previous cases of mumps, with severe symptoms, in adults. The pulse did not become so frequent as in septicaemia, and the eye remained clear and did not acquire that glassy appearance so indicative of a fatal issue. Dr. Goodell had never seen the involvement of the breast and ovary. A peculiar relation between the sexual organs and the glands of the neck was shown by a habit of the Roman matron who measured the throat of her daughter before and after the night of the marriage, to ascertain if the young husband had properly performed his marital duties, and if they had been properly received.

Hard-rubber Urethral Dilators.—Dr. Albert H. Smith exhibited a set consisting of ten pieces with two handles, into which they could be screwed; the smallest bougie was twenty millimetres in circumference at the point, and twenty-eight millimetres at the largest part, the tapering in each bougie being eight millimetres, and a difference of six millimetres between each one and the largest circumference of the next in the scale. The largest one was eighty-two millimetres at the largest part, and would be useful as a rectal dilator. He had been very much surprised at a statement made by Dr. Emnet at the last meeting of the Gynecological Society in Boston, that dilatation of the urethra almost universally caused laceration, and was followed by permanent incontinence of urine. Dr. Smith had been in the habit of doing it frequently and fearlessly, without hesitation, not only in disease of the urethra and bladder, but for exploratory purposes and for removal of stone, as a step in the operation of anterior eleytrophraphy, that by means of a finger in the bladder he might judge of the thickness of the walls in denuding the vaginal surface and place his sutures satisfactorily. He had never had incontinence of urine to last over twenty-four hours from this procedure.

Dr. R. P. Harris had seen a large number of dilatations of the urethra without any bad effect. He would consider the method of Dr. Smith better than any other plan, as it would
make a perfectly even and uniform pressure on every portion of the urethra, with a very gradual action, free from the dangers incident to the opening of any form of instrument with blades.

Dr. Goodell was much obliged to Dr. Smith for exhibiting these instruments, and would give a set of them. He had entirely dropped Simon dilators, and had for some time been using his little finger as the best dilator. He had not had any trouble from laceration or incontinence. In one case in which he resorted to dilatation and treatment to the mucous surface of the bladder as a cure for cystitis following labor, incontinence remained for a long time, but gradually disappeared. He knew of laceration and incontinence in two instances resulting from the use of the thumb as a dilator. Dilatation alone was a good treatment for many cases of irritable bladder.

Dr. Wm. H. Parish narrated the case of a widow operated on by Dr. Goodell by dilatation for the relief of a very aggravated case of irritable bladder, the result of a gonorrhoea contracted years before from her husband, and which had been followed by cystitis. It was greatly relieved for several months, but not cured, by dilatation, but the relief was only temporary. The patient passed under the care of Dr. H. Lenox Hodge, who cauterized the urethra by means of Paquelin’s cauter. In consequence of the illness and death of Dr. Hodge, she came again under the care of Dr. Parish, who commenced treatment by the injection of a solution of nitrate of silver, very strong at first, but weaker on subsequent applications. The trouble had passed entirely away. There were two causes of failure in dilatation: the first was too rapid expansion of the dilator; the second, changes in the mucous membrane as from inflammatory action, particularly if caused by gonorrhoeal poison.

Dr. Charles H. Thomas had lately procured a set of nickel steel instruments of about the same taper, and for the same purpose as those exhibited by Dr. Smith. The set consisted of sixteen pieces; each dilator tapered five mm. from the point to the largest circumference of the shank; they ranged from twenty-five to fifty mm. He had tried in some cases using every second instrument, making rises of three mm., but had found that the pain was increased by so doing. He had never known of a case of incontinence caused by dilatation, but had heard of such from the hands of two celebrated surgeons of this city. He thought dilatation to the size of the finger a good treatment for the relief of irritable bladder in connection with irritation of the urethra and neck of the bladder. He related the history of two cases in which this condition was complicated and made persistent by "sphincterismus" of the sphincter ani muscle; dilatation of the urethra in these cases, although a benefit, did not cure the trouble, but when this was added dilatation of the sphincter ani, so that two fingers could be introduced back to back, and a good dilatation secured, the patients were permanently cured.

Dr. B. F. Baer had practiced dilatation of the female urethra a number of times, and had had no instance of continued incontinence. He would, however, question the propriety of ever using a large-sized dilator, except for the purpose of removing a calculus from the bladder, and even in that case he thought it might be better to allow the stone in the grasp of the forceps to finish the dilatation than to use mechanical dilators to secure the full extent needed. In one instance incontinence lasted several weeks after dilatation, but final recovery was complete, solutions of carbolic acid having been applied in the mean time for the cure of an irritating of the bladder and urethra.

Dr. Parish would like to hear from Dr. Smith respecting the indications for probable success in treatment by dilatation of the urethra for the relief of irritation of the bladder.

Dr. Smith, in reply to Dr. Baer, remarked that no cavity of the body should ever be dilated beyond the actual necessities of the case; such a principle was unquestionable; but no form of dilator could be worse than the irregularities and roughness of a calculus, increased in size as it would be by the grasping forceps, which would present but two points of contact with the urethra, and render laceration quite probable. In a patient recently under his care, he had reason to suspect the existence of papillomatous growths on the mucous surface of the bladder; he dilated the urethra, using the largest of Simon’s dilators, and completing with a Molesworth dilator, expanded very slowly. He was able to evert the bladder through the urethra, and removed the vegetations by means of scissors. There was no laceration nor incontinence resulting from this procedure. The danger was in too great haste. In reply to Dr. Parish, he said that dilatation was usually resorted to for exploratory purposes, removal of stone, growths in the vesical wall, or to ascertain the thickness of the wall of the bladder, and to introduce a finger into that viscus to guide the sutures in plastic operations upon the vagina. Irritability of the neck of the bladder could generally be relieved by dilatation, but it sometimes failed to cure. Dr. Smith preferred hard rubber to plated metal as the material for the dilators; it was lighter in weight, was not liable to corrosion and was more easily kept clean. He thought the multiplicity of instruments in Dr. Thomas’s scale a disadvantage, and that time was lost and irritation caused by introducing several instruments in place of allowing one to remain a longer time.

W. H. H. Githens, M. D., Secretary.

NEW YORK CLINICAL SOCIETY.

A regular meeting was held May 25, 1888, Dr. Frank P. Foster chairman for the evening.

FOREIGN BODY IN THE HAND.—Dr. Robert Abbe presented a triangular piece of plate glass, an inch and three quarters long and half an inch broad, which he had removed from a man’s hand under the following circumstances: Three days before the patient came under observation he had thrust his hand through a window, receiving a transverse incised wound on the palmar aspect of the wrist, dividing one of the flexor tendons. The wound was sewed up by the surgeon who first saw him. The hand was swollen and had an angry look; the temperature was elevated, and the whole set of symptoms suggested strongly the presence of a foreign body. The wound was reopened, and, after considerable probing, a piece of glass was discovered in the palm, about three fourths of an inch from the wound. It was removed with some difficulty by means of dressing forceps. The apex of the triangular piece of glass was toward the fingers, and this had prevented the patient from extending the fingers completely. Dr. Abbe called attention to the importance of determining positively, especially in injuries by glass, whether any foreign body was still present before sewing up wounds.

Dr. L. Emmett Holt mentioned the case of a boy who received a wound of the hand with a toy pistol. The wound was thoroughly cleansed, and it was thought all foreign bodies had been removed. It was dressed antiseptically. Extensive suppuration followed; several counter-openings had to be made on account of the burrowing of pus, and it looked at one time as though he might have to lose the hand. After a month of waiting and exploring and poulticing, the boy brought back one morning a small bit of pasteboard, about two lines in diameter, which had been discharged spontaneously from one of the
In ten days all the sinuses were healed, and he made a quick recovery. The case illustrated how extremely difficult it was at times to detect foreign bodies in wounds, even though we might be almost certain that they were present.

**PROLONGED TAXIS FOR THE REDUCTION OF HERNIA.**—Dr. Anne also related a case of hernia which he had reduced without ether, after prolonged taxis lasting three quarters of an hour. The hernia had been down for four months, and was irreducible by the patient and by several surgeons who had previously seen the case. There were no symptoms of strangulation. His experience in this, and in quite a number of similar cases, had led him to place a very high estimate upon prolonged taxis. He had often worked half an hour without any apparent change in the tumor, and then in a few minutes had the whole mass slip back quite easily. He applied the same method to all cases of strangulated hernia, except those with acute symptoms. If taxis were carefully employed, any irritation which it produced he thought could be allayed by subsequent rest and the application of ice. He had not found elevating the hips during taxis of any service unless the patient were under ether. The constrained position usually made the parts more tense than before. Position was undoubtedly valuable when the patient was to be left for some hours. This was sufficient in many cases for reduction.

Dr. J. E. Winterson asked whether cold or hot applications had been found most valuable by members of the society in such cases. Personally he much preferred the use of cold. This was corroborated by the experience of all present.

Dr. W. H. Katzenbach said he had recently seen a case in which numbness and tingling, and a sensation of walking upon cushions, had apparently been produced by the wearing of a tightly-fitting truss for a double inguinal hernia. The patient was a gentleman past middle life. The symptoms had existed about four years—in fact, ever since the truss was applied. It had always given him more or less pain. He had been told that he had locomotor ataxia. Examination failed to reveal any anesthesia or hyperesthesia; the tendon reflexes were normal. No other symptoms were elicited. The patient was not worse now than formerly.

Dr. Winterson thought that, had the symptoms mentioned been produced by the truss, they ought to have grown worse in four years' time. He inquired if the posterior aspect of the legs was affected. It was difficult to see how pressure upon the inguinal and anterior crural nerves could cause symptoms in the soles and posterior aspects of the legs, which were supplied from the sciatic.

Dr. Katzenbach admitted that his examination had not been a very thorough one, and he was unable to answer definitely the question regarding the localization of the numbness and tingling.

**PSYCHOLOGICAL DISTURBANCES WITHOUT APPARENT CAUSE.**—Dr. A. A. Smith related the following two cases as illustrations of a series of seven or eight, closely resembling each other, which had recently fallen under his observation: One patient, a lady of forty-seven, past the change of life, suddenly, and without assignable cause, became exceedingly nervous, very irritable in disposition, and easily moved to tears. Her sleep was very much disturbed, and there was almost complete anorexia. There were no pains, headache, or constipation. Nothing pointed to any disturbance of the stomach or liver. There was great mental depression, and a constant dread that something serious was about to happen. The patient had been sensible and healthy previously, except a pelvic cellulitis, which she had had three years before.

The second patient was a widow of forty, of good constitution, who had lately had loss of flesh and of appetite, poor assimilation, and vomiting. Her extremities were cold much of the time, she tired easily on exertion, complained of spots of numbness frequently after rising, and apprehended paralysis. She had no pain. She was easily moved to tears, at which she became very angry with herself. She perspired easily. She had always slept well before, but now only two or three hours during the night. As in the previous case, no assignable cause was found. The two cases did not occur in the same family or among friends. He was at a loss to explain these cases unless by some possible atmospheric influence—such, perhaps, as that which early in the season had produced so much pneumonia, or physical depression.

Dr. Anne thought we were not enough on the lookout for such epidemic influences. He had been much interested in studying diarrhoea occurring epidemically in hospital wards from time to time and lasting a day or two. He said the mucous membranes, being the most exposed parts, were most likely to suffer from atmospheric influences. He mentioned a case occurring in a lady of stotical habit who from an ordinary cold and bronchitis suffered from great prostration for a day or two beyond what would be explained by the physical symptoms. She shed tears copiously.

The Chairman alluded to atmospheric conditions affecting other diseases with which we were more familiar. Ergotism was much the most frequent from the middle of April to June. The majority of pelvic inflammations occurred in mid-winter; perhaps we had no better term to apply to these influences than the genus epidemics of the old writers.

Dr. J. H. Emerson spoke of the frequency of epidemics of catarhal conjunctivitis lasting a week or more.

**AN ANOMALY OF THE STUMP OF THE UMBILICAL CORO.**—Dr. Anne related the following case: Three weeks before he had delivered a primipara, aged sixteen years. The cord was tied as usual, and in a few days sloughed except about three fourths of an inch of it. This still remained, resembling a small penis in appearance. It was healthy, and showed no tendency to come away. It was covered by integument and capped by a few small erosions. It was a little constricted at its attached end. He was certain that no intestine was included in it. A little haemorrhage occurred on the third or fourth day, but did not change the size. The mass did not pulsate. He had decided to ligate it.

No member present could recall having seen or heard of a similar case.

**UNUSUAL EFFECTS FROM THE BROMIDES.**—Dr. E. G. Janeway mentioned a case in which hallucinations of sight had been produced by bromide of potassium. The patient was a man of forty-six years, who had suffered from intense headaches for three months. There was no history of erythm. He had taken bromides before, and said they always disturbed his vision. He was ordered fifteen grains of bromide of potassium three times a day, and twenty grains at night. It was combined with the iodide in moderate doses. After a week the patient complained of seeing a third person in the room, and of other hallucinations of a similar nature. The bromide was then stopped and the iodide continued. In two days all the symptoms were gone. The dose of the iodide was doubled afterward, but the symptoms did not recur. Dr. Janeway called attention to the fact that delirium was often referred to the disease, when in reality it was from the drugs employed in treatment. This was noticeable the case with salicylic acid or salicylate of sodium, morphine, and wintergreen.

Dr. Winterson had seen a case in which hallucinations of sight had been caused by immense doses of the bromides. They had preceded the other symptoms of bromism. The patient took at one time six drachms in twenty-four hours. The dose
was reduced to ninety-five grains a day, when oedema of the lungs developed, but he finally died of heart-failure.

Dr. Winters mentioned another case in which forty-grain doses three times a day had produced the hallucination of threads hanging all about the patient, at which he was constantly picking.

Dr. Jane Way stated that there was no hysterical element in the case first mentioned, and that there were no other symptoms produced by the drug except a degree of apathy. He had seen now four cases in which the bromides had produced death when given to excess.

**Tumors of the Stomach.**—Dr. Jane Way related two cases—one of cancer, and one of lympho-sarcoma of the stomach—which had presented some quite anomalous and obscure symptoms. In the case of cancer, the prominent symptoms were neuralgic pains in the arms and legs, which were found on autopsy to depend on cancer of the vertebra and dura mater. This patient also presented a tumor under the left lobe of the liver, which pulsed and gave a double murmur. The usual symptoms of gastric cancer were absent. There was no vomiting. The tumor was found situated at the lesser curvature. It was not ulcerated, and caused no stenosis. This was the fourth case of cancer which he had seen that had given rise to a pulsating tumor and a double murmur. The tumor pressed upon the aorta and caused stenosis. The first murmur he thought was due to the systolic wave, and the second to the diastolic wave.

In the case of lympho-sarcoma the prominent symptoms were neuralgic pains in the legs. The tumor occupied about the same site as the former one, and involved likewise the retroperitoneal glands and psoas muscle, to which latter fact the pains were due.

**Miscellany.**

**Therapeutical Notes.**—Action of Mixtures of Air and Vapor of Chloroform; a New Method of Anaesthesis.—M. Paul Bert (" Gazette hebdomadaire de Médecine et de Chirurgie," July 6, 1853) has found that, if a dog be made to breathe a mixture of 4 grammes of chloroform, vaporized in 100 litres of air, the animal remains conscious throughout the whole of the experiment, which was prolonged in one case to a period of nine hours and a half. In this case the rectal temperature fell to 32° C. [95° F.]. With a mixture of 6 grammes of chloroform vaporized in 100 litres of air, death took place in about seven hours, with a temperature of 31° C. [88° F.]. Consciousness remained throughout, though it was inspired, especially during the last hours, when the animal was very cold. With a mixture of 8 to 100 grammes of the skin and even of the cornea took place, very gradually, and after a period of excitement. Death occurred at the end of six hours, the temperature being reduced to 30° C. [86° F.]. With 10 to 150, insensibility supervened in a few minutes. The sleep was absolutely quiet, and death resulted without any stage of excitement, in two hours to two and a half. The temperature was then from 32 to 38° C. [95 to 95° F.]. With 12 to 100, speedy insensibility without excitement; death in an hour and a quarter; temperature 35° C. [95° F.]. With 14 and 16 to 100, death in three quarters of an hour, temperature, 38° C. [100° F.]. With 18 and 20 to 100, death in half an hour. With 30 to 100, a death in a few minutes. In all these experiments narcotism had been performed upon the animal. The chloroform was perfectly pure.

The experimenter calls particular attention to the following facts: 1. Whether death supervened quickly or slowly, the heart always continued to beat after the cessation of the respiratory movements. 2. Even after an anesthesis of several hours, no chloroform appeared in the urine. 3. When the proportion of chloroform was very small, an enormous amount of it was inhaled without causing any objective phenomena except the lowering of the temperature. 4. With a slightly greater proportion of the anesthetic, the heart passed through a great lowering of temperature, but consciousness persisted until life was extinct. Furthermore, the chloroform acted only on the nutritive processes, probably by producing torque of the ultimate cells, as the cells in beer were made dormant in the experiments of Claude Bernard. 5. With still greater proportions of the anesthetic, when unconsciousness comes on quietly, death is always the result of the continued inhalation of the chloroform mixture. The stronger the mixture the more quickly does death take place, and the less the temperature is lowered. A dog was made to inhale a mixture of 12 grammes of chloroform to 100 litres of air. At the end of some minutes, when he was well anesthetized, he was given a mixture of 8 to 100. This, which if used from the beginning would cause unconsciousness very slowly, and only after a stage of much excitement, was quite sufficient to continue the action of the stronger mixture. As it is not fatal unless administered a very long time, it rendered it possible to continue the anesthesia perfectly for more than three hours without any danger to life, and without embarrassing the respiration or circulation. The temperature alone was affected. This is a very simple proceeding, and requires nothing but the use of two eschosphate bags and a respirator.

Before these facts are applied by surgeons, it remains to be determined of what strength anesthetic mixtures should be made, to produce on human subjects the same effects as those in the foregoing series of experiments upon dogs.

**Bivioide of Mercury Ointment as a Remedy for Acute Gout.**—Surgeon-Major Albert A. Gore, of the British Army in India (" Dublin Journal of Medical Science," June, 1883), reports the successful treatment of thirty cases of acute gout by the bivioide-of-mercuric ointment. The patients were all native soldiers. They were subjects of bronchocele while stationed in the foothills of the Himalaya mountains. The ointment was rubbed in for about ten minutes, the enlarged gland being well exposed to the sun or to a brisk fire during the immersion. The average duration of treatment was about twenty-three days. In ordinary cases, a single application, if properly made, was sufficient. Sometimes subsequent applications were required. There were no cases that refused to yield to treatment.

**Crotona as a Remedy for Malignant (Hemorrhagic) Scurlatina.**—Dr. John W. Hayward, of Liverpool, England, has come to the conclusion (" Lancet," July 14, 1882) that crotona is a most valuable remedy in those malignant cases of hemorrhagic scurlatina to cope with which there has been hitherto no adequate medicinal agent. After waiting to test the drug with great care, he has reported two very virulent cases which were successfully treated by him. In one case the patient was moribund when the crotona was resorted to, she having grown steadily worse under all previous treatment. The mode of administration was as follows: The cuticle was removed from about the throat with a cantharidea blister. To the exposed surface a compress sprinkled with
crotalus was applied, and a dose dissolved in a teaspoonful of water was dropped on the tongue every half-hour. The beneficial effects were apparent almost immediately. The breathing became less labored, irregular, and sighing. The pulse, which had been 160 and scarcely perceptible, fell within twenty-four hours to 120; and all its characteristics were improved. The rash, which had been brown, rough, scanty, and but faintly visible, came out freely on the body and legs, and was of a purple color. The head, previously thrown upward and backward, assumed a more natural position. In the course of twelve hours more the strength was recovered, the pupil dilation and oedema of the toes and fingers, which had entirely prevented swallowing, abated so that drinking was accompanied with but little difficulty or pain. The respiration was almost normal. The pulse was 100, and was gaining in force and fullness. A favorable prognosis was given, and the progress was so rapid that the patient was well within nine days of the attack. She was taken sick on the 8th ult., and nearly dead on the 7th; crotalus treatment was begun on the morning of the 7th; it roused her almost immediately; the recovery was so rapid that a favorable prognosis was given on the 8th, and the patient was well on the 14th.

Dr. Hayward states that this case is not an exceptional one. He has witnessed "over and over again" the marked power exercised by crotalus in these malignant cases of hemorragic scarletina. He believes that it arrests the blood-poisoning which occasions the disease.

*Casuar Sagrada for Constipation.*—R. A. Douglas Lithgow, LL.D., M. R. C. P. E.I. ("British Medical Journal," July 14, 1883), warmly advocates the use of *Casuar sagrada* as almost a specific, under favorable conditions, for chronic constipation. It is of special value in cases characterized by torpidity of the liver and an atomic condition of the stomach and bowels. It seems to act as a tonic to the pneumogastric and sympathetic supplies of the *præss elen*, and the associated visceri. It thus corrects defective or perverted biliary and intestinal secretions, and relieves adynamic conditions of the nervous and muscular forces of the digestive apparatus. It will often tone and regulate the alimentary tract and its appendages when all other remedies fail. *Casuar sagrada* is also of special service when chronic constipation is associated with hemorrhoids. It relieves congestion of the portal circulation and venous congestion of the stomach and intestines generally; moreover, instead of irritating, as many cathartics do, it exercises a soothing effect upon the rectal mucous membrane. In those troublesome cases in which habitual constipation is complicated with flatulent dyspepsia—vomiting alike to patient and practitioners—it is generally followed by highly gratifying results. The writer knows of no therapeutic agent which is altogether so reliable and satisfactory in this numerous class of cases.

Small doses, frequently repeated, are more beneficial usually than large doses. To begin with, ten or fifteen drops should be given two or three times a day, either before, with, or immediately after meals. In a week, if there be little or no improvement, the dose should be increased until the bowels have been freely relieved, when it may gradually be decreased in amount and frequency, until healthy intestinal secretions and increased peristaltic action restore the alimentary canal to its normal condition. The dose for a child a month old is from two to five drops. In the exceptional cases in which it causes some gripping the dose may be decreased, or the drug may be combined with a suitable antispasmodic. Moreover, the intelligent physician may often advantageously combine it with lacticopent, dilute hydrochloric or nitric acid, mac vomiaca, aromatic syrups, etc.

[Introduced by Dr. Lithgow was the fluid extract made by Messrs. Parke, Davis & Co.]

The International Medical Congress of 1884.—The president and secretary-general send us the following communication: "Reminding you that the Eighth International Medical Congress (according to the notice already published some months ago in the medical journals) will be held in Copenhagen from the 10th to the 16th of August, 1884, we have the honor of communicating to you that the General Organizing Committee, formed for the preparatory work, is composed of the following members, living either in or near Copenhagen: President, Professor P. L. Poulsen, Secretary-General; Dr. O. Bloch, Dr. C. J. Salomonsen, and Surgeon-General Joh. Moeller. Honorary Treasurer: Professor Dr. E. Hansen Grut, besides the presidents of the special committees of the Section of Anatomy: Professor Chievitz. Physiology: Professor Dr. P. L. Panum. General Pathology and Pathological Anatomy: Professor Dr. C. Reizis. Medicine: Professor Dr. F. Tricker. Surgery: Professor Dr. Holmer. Hygiene and State Medicine: Dr. E. Horremann. Military Surgery and Medicine: Director-General of the Medical Department of the Army Salomon. Mental and Nervous Diseases: Professor Dr. Stienberg. Obstetric Medicine and Surgery, Gynecology: Professor Dr. Studdfield. Pathological Anatomy: Professor Dr. Hirschsprung. Ophthalmology: Professor Dr. E. Hansen Grut. Diseases of the Skin and Syphilis: Professor Dr. Haslund. Diseases of the Ear: Dr. W. Meyer. Diseases of the Throat: Dr. W. Meyer.

"The special committees formed for the foresaid sections have, when they found it useful, completed their number by members living outside Copenhagen, partly in Denmark, partly in the other Scandinavian countries. In order that the meeting of so many distinguished medical men, whom we hope to see on this occasion, may be as advantageous as possible, the organizing committee, following the example of the later congresses, will communicate with distinguished men of different branches and of different countries, in order to prepare a programme. This programme, as well as the rules, will be forwarded as soon as possible to every one qualified to participate in it. In order that the programme may be ready as soon as possible, we should be pleased if communications referring to the work of the Congress were sent to the . . . secretary-general before the 1st of October next, so that it may be possible for us to have regard to them in arranging the definite programme. The programme and rules will be forwarded as soon as possible to every one qualified to participate in the Congress who, within the limited time, has announced to the secretary-general his interest in the Congress, and his eventual intention of participating in it, if possible also which section he chiefly intends joining."

A Prize for the Artificial Cultivation of Vaccine.—A London correspondent of the "Union médicale" states that the Grocers' Company, of London, offers a prize of £1,000, open to universal competition, to the discoverer of a method by which vaccine may be cultivated in an indifferent medium. The process must allow of the indefinite multiplication of the virus by successive generations, and the product of each generation must have the properties of natural vaccine lymph, so far as the time allowed may suffice to determine. A description of the process, written in English, must be submitted before December 31, 1886, and the prize will be awarded as soon after that date as possible. Further information may be had by addressing the clerk of the Grocers' Company, Grocers' Hall, London.

The Disinfection of Mail Matter at Marseilles.—According to a writer in the "Union médicale," the laboratory used for disinfecting the mail matter brought to Marseilles from an infected port consists of a close room provided with a huge table for holding the contents of the mail-bags, previously untied. The postal agents of the vessel attended to this preliminary operation, and then withdrew to the ship or to the lazarette, having hermetically closed the openings of the fumigating chamber. Phenolated or chlorinitated vapor is then forced into the latter for a suitable length of time, after which the city post-office employees enter it by another door, after it has been aired, and fill the purified bags. Thus there is no communication between the quarantined officials and those of the town.

The Treatment of Hay Fever.—Mr. W. F. Phillips ("British Medical Journal") writes: It is just over five weeks since a lady placed herself under my care for the treatment of hay fever, or summer catarrh—a very much better name. She had suffered severely for many years, and sometimes from the end of May to near the end of July with little or no intermission unless she kept indoors. Her mother, it is worthy
of remark, was very sensitive to the odor of certain flowers, and was affected by some of them even to the extent of fainting. She was not subject, however, to summer catarrh. Knowing how exceedingly unsatisfactory is the treatment recommended and practiced for this disease, as is sufficiently evident from the recent communications to the journal on the subject, I sought for rational indications that might guide me to the selection of a remedy. I thought of the nostrils that seems to underlie most cases of this kind, and to constitute the essential cause or predisposition on which the disease depends; of the characteristic symptoms of the malady: the injection of the conjunctiva, the hyperemia and hyperaesthesia of the nasal cavities, the excessive secretion of tears and mucus; and then I betothought of a drug whose properties most closely approached the symptoms to control such symptoms. Belladonna was the drug that suggested itself at once, and I determined to give it a trial, all the more happily because I remembered how strikingly useful on similar indications, and by a parity of reasoning, I had often found it in ordinary conjunctivitis and simple catarrh. I began with the following prescription: B. Succi belladonnae, ηεξίτε; aquam ad ⅓ fl. Misc. A teaspoonful to be taken every hour till relief is obtained. The medicine was taken without the production of any undesirable effect, and with very marked advantage indeed—an advantage that became still more evident and unmistakable, both to the patient and myself, when the dose was increased from one minim to one and a quarter (half a drachm in three ounces). Once, too, when the eyelids were especially tender, the patient was advised to use the mixture as a lotion to the affected parts, and this local application was found to be a most useful addition to the internal administration of the remedy. Repeatedly, when the symptoms of an attack had been allowed to begin, the patient found prompt relief after a few doses of the drug, the catarrhal affection disappearing first, and then the asthmatic; and, on taking it regularly every day after the malady had been subdued, she has found to her delight that she can take her walks abroad through blooming grass and flowers without the least protection or precaution—a thing she had not been able to do for years before. The patient, remembering, no doubt, the failure of past treatment, pronounces the remedy "a great success"; but, however satisfactory the case may be, it is, as far as I know, a solitary one, and therefore stands in need of confirmation and support.

The Rush Medical College, of Chicago.—The "Cincinnati Medical News" states that a hospital, of a capacity of about fifty beds, is to be built on ground adjoining the college building.

Arctocarpus Incisa in the Treatment of Entistipelas.—According to Surgeon C. H. White, of the navy, the natives of Tahiti treat entistipelas by coating the inflamed part with the juice of the Arctocarpus incisa, which acts like colloidion.

Army Intelligence.—Official List of Changes of Officers serving in the Medical Department of the United States Army from August 4, 1883, to August 11, 1883.—Macrider, David L., Lieutenant-Colonel and Surgeon. Leave of absence extended one month. S. O. 89, Military Division of the Missouri, August 4, 1883. McPartlin, Thomas A., Lieutenant-Colonel and Assistant Medical Purveyor. Relieved from duty in charge of the purveying depot in San Francisco, California, to take effect September 1, 1883, and will then proceed to New York city and relieve Assistant Medical Purveyor Ebener Swift of the charge of the purveying depot in that city. Assistant Medical Purveyor McPartlin will transfer all funds and public property in his possession to Medical Storekeeper Henry Johnson, who, until further orders, will perform the duties of acting assistant medical purveyor at the purveying depot in San Francisco. Par. 5, S. O. 183, A. G. O., August 9, 1883. Forwood, William H., Major and Surgeon. To proceed to Fort Washakie, Wyoming, and Fort Ellis, Montana, on public business and return. S. O. 87, Military Division of the Missouri, August 2, 1883. Woodward, Joseph J., Major and Surgeon. Leave of absence, granted on account of sickness by S. O. 34, extended six months. S. O. 179, A. G. O., August 4, 1883. Byrne, Charles B., Captain and Assistant Surgeon. Relieved from duty at Fort Craig, New Mexico, and assigned to duty at Fort Lewis, Colorado. Par. 3, S. O. 161, Department of the Missouri, August 6, 1883. Laurerdale, John V., Captain and Assistant Surgeon. Granted leave of absence for two months, to take effect on or about the 15th inst. Par. 2, S. O. 90, Department of the Missouri, August 6, 1883. Banister, John M., First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of the Missouri and assigned to duty in the Department of the East. Par. 5, S. O. 183, A. G. O., August 9, 1883. Carter, William F., First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of Texas, and assigned to duty in the Department of the East. Par. 5, S. O. 183, A. G. O., August 9, 1883. Kane, John J., First Lieutenant and Assistant Surgeon. Relieved from duty in the Department of the Missouri and assigned to duty in the Department of the East. Par. 5, S. O. 183, A. G. O., August 9, 1883. Owen, W. O., Jr., First Lieutenant and Assistant Surgeon. To proceed from Vancouver Barracks to Fort Walla Walla, Wyoming Territory, and report to the commanding officer of the latter post for temporary duty. S. O. 101, Department of the Columbia, July 27, 1883.

Naval Intelligence.—Official List of Changes in the Medical Corps of the Navy during the week ending August 11, 1883.—Passed Assistant Surgeon J. D. Gatewood, orders to the Trenton revoked and ordered to the Kearaunch. Assistant Surgeon Horace B. Scott, detached from the Receiving Ship Franklin, at Norfolk, on the 30th inst, and ordered to the Trenton, September 1st. Passed Assistant Surgeon A. A. Austin, detached from the Richmond, and waiting orders.

Lectures and Addresses.

A LECTURE ON
THE PHYSICAL BASIS OF PHYSIOLOGY.
DELIVERED AT THE BELLEVUE HOSPITAL MEDICAL COLLEGE,

By W. H. ALLCHIN, M. B., F. R. C. P., F. R. S. E.,
LECTOR OF PHYSIOLgy AND PATHOLgy AT THE WESTMINSTER HOSPITAL MEDICAL SCHOOL; PHYSICIAN TO THE WESTMINSTER HOSPITAL, LONDON.

Gentlemen: Some ten days ago, when the opportunity of addressing you was given to me, I will confess to having accepted the offer with feelings of gratification, and to having been much flattered by the proposal. To-day, with the recollection of the eloquent and masterly lecture delivered yesterday by Professor Flint, I feel no small consternation at the position in which I have allowed myself to be placed. For, though not unaccustomed to lecture, it has not been my privilege hitherto to meet so large a class as I see now before me, nor to come into direct contrast with so able and graphic a teacher as he whose place I occupy assuredly is. The lucid and telling manner in which yesterday the structure of the liver was described, I have never heard the like of, and, though familiar to you, I congratulate you, gentlemen, on having such a master, whose fame has reached us in my country, but whose powers as a teacher I only yesterday fully realized.

To occupy your time with a lecture on the regular subjects of the physiological course would be absurd and impertinent in me, and would probably and rightly be resented by you. It would be depriving you of the rich eloquence, and forcible exposition of your professor, and offering you in its place, for no good reason, a weakly substitute. When, therefore, I turned over in my mind what I should say to you, I was somewhat perplexed as to how I should comport myself with the least discredit, until I remembered that there was yet another side; that, besides the hard facts and records acquired by patient observation and experiment, there were certain inferences that might be drawn, certain principles which might be indicated, of the greatest value if properly applied. In thus thinking I was not altogether unmindful of the charge of presumption that I was thereby possibly laying myself open to. Scientific men are very properly shy of principles and those who propound them, and it only comes to him who, like Charles Darwin, had carefully observed and recorded facts, to be listened to with respect when he enunciates a general principle. Nevertheless, speaking as a teacher of physiology for the past eighteen years, I am distinctly of opinion that the occasional expression of the principles, however provisional they may be, that seem to connect a number of ascertained facts together is of benefit to the student. For it must not be forgotten that physiology is but one of the many subjects that engage the student's attention in his too short course, and anything that serves to give coherence to his knowledge of the isolated facts is of positive advantage to him, provided he clearly accepts the theories as being open to amendment or contradiction, and does not mistake them for absolute truths.

In a science like physiology, which, though perhaps out of its infancy, is in a very incomplete state, but at the same time is rapidly progressing, a good deal of allowance has to be made for the way of looking at things, and more is wanted by the worker at his subject than the mere knowledge of the facts obtained by observation or experiment. It is requisite that he have a habit of mind, that nothing but time will give, accurately to appreciate and place the information so obtained. Especially, as it seems to me, also is this the case with those who, after the too brief study of physiology which the curriculum compels, enter as physicians on the practical application of its truths in abnormal conditions. How desirable, then, is it that some prominence should be given to these principles in the ordinary course of lectures on the subject! Throughout life the problems of physiology present themselves to the medical man, long after the facts that he has gathered in the lecture-room and from his text-book are forgotten. I propose, then, to occupy your time to-day with the contemplation of certain theoretical considerations. Partly for the reasons I have given of what I consider the value of such a course, and partly because of the exceptional character of my appearance before you, I would propose to treat of some subject that may be fairly completed within the time at my disposal.

It is not my intention to contribute to the positive knowledge of physiology, that is so forcibly and graphically put before you by your teacher, but rather to ask you to look at some of that knowledge from a point of view that I venture to think may be somewhat new to you, and yet worthy of your attention; and, while I shall be very elementary, I shall hope to be suggestive. Not so many years ago, and quite within my recollection, when there was gradually yet widely developing that method of scientific inquiry and investigation which obtains among us now, physiology with its really small array of facts, and hampered with most obstreperous doctrines, was looked at, in common with other branches of biological science, from a vague and uncertain standpoint, and with only the slightest appreciation that the same broad and general principles were underlying the phenomena presented by both animate and inanimate objects. Time was, and not so long ago either, when a living thing, whether animal or plant, was regarded, except, perhaps, by very few, and by them most imperfectly, as wholly inexplicable and mysterious in its action, not subjected to the same laws as govern inanimate matter, and not to be the object of experiment and observation similar to those applied to the investigation of the properties of non-living substances. There was a sort of half-expressed idea that life was altogether apart from other natural phenomena, and that the beings which manifested it were subject to special laws of their own, from which the rest of the world was free, and which it was impossible and even wrong to inquire into. I am not sure that the idea does not still lurk among us. To my mind, one of the most important advances made in natural science lately has been the steady
recognition that living beings are to be interpreted in their activities by the same fundamental principles that explain the manifestations presented by objects that do not live; or, in other words, that, when investigating the functions of an animal or plant, we are to recognize that many of those functions are identical with the properties that we find associated with materials that do not form, and have never formed parts of living things; and that the peculiarly characteristic functions of living things (to which I can see no objection to apply the term "vital," as indicating their limitation to objects we call living) are manifestations of energy connected with a certain peculiar form of matter, and may or may not be correlated to the so-called physical forces.

This placing, so to say, of physiology—this recognition of its position and relationship to other sciences—this rendering it amenable to the same universal principles, is, I can not help thinking, an achievement of very recent years that is quite worthy to rank with the doctrines of the "correlation of the physical forces" and "evolution," though it has not been associated so distinctly with the name of any particular worker as those two grand declarations have been.

Setting aside metaphysical speculations, the cosmos presents itself to us in two aspects, or, if you please, we are conscious of possessing two fundamental conceptions of the universe, to which we apply the terms "matter" and "force." We only appreciate the one through the other; we can not conceive of matter apart from the properties it displays, which properties—such as hardness, elasticity, rigidity, heat, and the like—are manifestations of force, apart from the material through which it is evolved. To this primary conception are added certain hypotheses, which, though incapable of direct proof, afford the most satisfactory explanation of most of the phenomena of the material world, and are accepted as forming the fundamental data upon which all experimental science is based.

Foremost among these hypotheses is the assumption that matter is absolutely indestructible; and, though capable of undergoing the widest range of alteration in condition, as expressed by the terms solid, liquid, and gaseous, and of entering into the most varied combinations, and of being again and again decomposed and rearranged, it is strictly limited in quantity, and is not subject to addition by creation. That matter should be removed out of existence is, with our present views, unthinkable, though daily experience shows us that it may undergo almost endless change in condition.

Another and most important theory is, that matter is constituted of atoms possessed of definite characters. While it may be said that there is nothing so small that we can not conceive of it being halved, it is assumed in relation to these ultimate atoms that they are of fixed sizes, and can not be further divided without change of nature; in short, for example, that, at a certain stage of subdivision, a piece of gold ceases to be any longer gold, if the process be continued. Though attempts have been made to express the sizes of such atoms, the figures convey to our minds no idea of their excessive minuteness. Inseparably associated with this notion of finite atoms is the assumption that they are in a constant state of motion or vibration in various planes.

Our present knowledge of the composition of matter leads us to recognize some sixty-five or sixty-six so-called "elements" or species of matter, which, while able to exist in various states, are themselves incapable of further decomposition. The ultimate atoms of these elements differ among themselves in the proportion in which they tend to combine with each other, such proportions being constant for each element in all circumstances. This value in combination is an inherent property of atoms, and is known as their "atomicity," being expressed in figures which are termed the "atomic weights," "equivalents," or "proportional numbers."

The atom, then, is an indestructible, indivisible unit, in a perpetual state of vibration, and possessing a definite weight, which represents the proportion in which it always enters into combination with other atoms.

Another of our fundamental hypotheses deals with the relation that matter bears to the force it manifests. This word "force," defined as "the power of doing work," may be taken as denoting the properties that any given matter displays; and, as already said, as we can not conceive of matter apart from its properties, so we can form no useful idea of force distinct from the substance which shows it. This relationship may be thus postulated: that force is the outcome of the condition of matter, dependent on the mode of vibration of its constituent atoms, and that the various forms of force are but different modes of such vibration.

The most universal form of energy possessed by the atoms is the attraction they manifest for each other, to which the name of "chemical affinity" has been given. In virtue of their atomicity the proportions in which they enter into combination are constant for each element; but the readiness or force with which union takes place is of great variability, some elements uniting with the greatest facility, others only with much difficulty. The elements, therefore, may be said to be "elective" in their affinity, this property being also influenced by the conditions—such as heat—under which the union takes place. To this power we owe the countless variations of matter, of the compositions and decompositions of which chemistry treats. Hitherto the term atom has been employed to denote the ultimate particles of matter, more particularly of the chemical elements: to the corresponding smallest particles of bodies compounded of one or more chemical elements the word "molecule" is applied, and such molecules which are inconceivable of further division without decomposition are, equally with atoms, assumed to possess definite sizes and modes of vibration.

Another form of attraction, termed "cohesion," determines the degree of solidity or fluidity of matter, and in the passage of solids into liquids, and then into gases, this force of cohesion has to be overcome by means of some other form of energy, such as heat. Closely connected with the amount of cohesion existing between the compound molecules of a given substance are its flexibility and elasticity.

The varieties of energy known as heat, light, and elas-
ticity, are equally regarded as manifestations of molecular motion.

To all such forms of force the term "physical" is collectively applied, and, just as chemistry treats of the phenomena dependent on manifestations of chemical affinity, whereby the composition of substances is altered, so "physics" may be applied to the investigation of those changes which take place in matter, but are unaccompanied by its decomposition.

Directly following from this concept of energy is the law of the correlation of the forces and their mutual convertibility, which asserts for force the same indestructibility which matter possesses. The conversion of heat into light, of light into sound, of heat into electricity, and this again into mechanical power, is well known, and the best arrangements for such conversion are problems of the greatest economic importance.

Such, then, briefly stated, are some of the principles upon which every scientific observer now proceeds, whether it be for the study of the nature and movement of the planets, or for the more directly domestic questions of lighting, heating, and mechanical power. Given so much matter, we can, under favorable conditions, so alter the planes of motion of its ultimate particles as to transform the energy it manifests into force of some other kind. These favorable conditions mainly consist in the application to the given material of some force which, through the agency of the matter, reappears in some other form.

Nor are such considerations to be limited to the investigation of non-living matter. They are common to the entire material world, and equally lie at the root of our understanding of living things.

A distinction has already been drawn between those properties which a living being enjoys in common with all inanimate objects, and which we designate physical, and those which are met with only in plants and animals when alive, and which on that account we speak of as vital. And the question has been raised as to the possibility of these groups of energies being correlated.

Concerning such qualities as the cohesiveness, the flexibility, or the elasticity of the different tissues, nothing need here be said, since the same qualities are possessed by the tissues and organs after death, so long as decomposition has not occurred. But, limiting our attention to the phenomena presented by the living body, we notice that it manifests such forms of energy as heat and electricity, which are in all respects identical with the same forces when we artificially produce them in our fires and batteries, and which, so far as we can ascertain, depend for their production upon exactly the same conditions in both cases. When the tissues are dead, these properties, by no means the attributes of living things only, are no longer manifested. The other and essentially vital characteristics have this very significant point about them, that we are unable to imitate them artificially; that is, we can not arrange matter with that molecular constitution which shall liberate a nervous impulse, and we can not apply any of the forms of physical energy to any substance and obtain a transformation of that energy into a muscular contraction. But there was a time when we could not convert a ray of light into sound. And there are not wanting those who assert that non-living material does, under certain conditions, become arranged in that form which displays all the characteristics of life. Passing on, then, to consider these distinctively vital forms of force somewhat more fully, we find them to be of two kinds, which, although invariably associated and dependent, the one on the other, are so far as we can judge separate and distinct. The first is the power by which the living tissue (protoplasm) converts the material with which it is supplied (food) into its own substance, or the process of assimilation as it is termed. In virtue of this power, the animal or plant grows and increases in bulk and complexity, and subsequently maintains its full-grown size. How this is done we are profoundly ignorant, but it would certainly seem to be of the nature of a chemical change, whereby the atoms and molecules of the ingesta are built up in an increasingly complex manner, differing in degree only, but probably not in kind, from chemical compositions with which we are familiar. Between the articles of diet as they occur in our meals and the tissues of the body which they ultimately form, are many stages, some few of which we can trace, but, though unable to see all, we need not at once assert the darkness to be impenetrable. The other essentially vital characteristic is the ability that the protoplasm has of responding to a stimulus, of manifesting some energy, that is to say, when such agents as the electric current, moderate heat or cold, weak acids or alkalies, or the mere mechanical irritation of pricking are applied to it. This power is known as the "irritability" of protoplasm. The response shows itself in various ways: the most general and easiest to observe is the alteration of shape that the stimulated substance undergoes; it moves; different varieties of this movement are to be recognized, but they are all modifications of one and the same property, which is termed "contractility." It is in virtue of this power that plants and animals are able to move from place to place, and that the beating of the heart, the act of breathing, and the numerous muscular activities of the body are performed.

Another form in which the irritability is displayed goes by the name of nervous force, including many phenomena of an extremely complex character. Consciousness, the production of sensations, the origination of impulses or stimuli that call forth on the part of the muscles contractility, whether voluntary or involuntary, the influence exerted over the nutrition of the tissues, are all forms of energy liberated by the substance we call nervous. In speculating as to the exact nature of these manifestations we remember that a due supply of oxygen is needful, and that there exists, diffused through the protoplasm of the muscular fiber or nerve cell, an amount of fuel substance, probably hydrocarbon, in an extremely minute state of subdivision. We further know that the waste of the nitrogenous tissue does not take place in proportion to the work done, but rather that the actual source of the force is the oxidation of this fuel substance, appearing, under the influence of the excessively complex and unstable protoplasmic molecule, as either muscular or nervous energy.

A third form of protoplasmic irritability is more dis-
tinctly of a chemical character, though the exact processes cannot be formulated, nor even artificially imitated. Under the suitable conditions of proper supply of blood, certain specialized areas of protoplasm secrete various fluids, some of which, as the perspiration, are thrown off as waste matter; others, as the saliva and gastric juice, are more or less completely reabsorbed after doing solvent work in the process of digestion. Although much of the work done by the glands is entirely that of a filter whereby certain constituents of the blood are strained through the layer of epithelial cells which form the essential part of the gland, yet other constituents of the secretions are especially manufactured by these same cells from materials furnished by the blood. To what extent the epithelial cells suffer, or whether even these specific constituents are really the results of cell destruction, is as yet undetermined, but we only recognize these substances as being formed by living protoplasm.

Such, then, are the distinctive properties of living matter. In the simplest forms of animals and plants we find them all embodied in the same speck of protoplasm, which may be completely structureless, or may present only the first traces of organization conferred by the presence of a nucleus. Such a speck is everywhere contractile, everywhere irritable, and, with no distinction into specialized parts, there is no separation of function. Between such a one and the highest forms of existence, from the physiological point of view there exists but a difference of degree, progressively increasing subdivision of the labor of life with a coincident increasing complexity of structure. The life history of the lowest monad equally with that of the highest animal consists but of manifestations of contractility and irritability. The object attained in both cases is the maintenance of an existence which itself depends on movements directed to the acquiring of food, to the digestion and assimilation of that food, finally to terminate in special manifestations of contractility, which result in the reproduction of the species.

In attempting to investigate the fundamental nature of these forms of vital energy we are beset by many difficulties. But our difficulties are not diminished by refusing to consider them as being essentially states of matter, if not even varieties of molecular motion. There are no real grounds to warrant our attributing them to any cause different in nature to the cause of the physical forces, but, on the contrary, many reasons which irresistibly point to such being the case. In the first place, it is only in connection with one special kind of matter that these energies are exerted, and this exceedingly complex, unstable substance (protoplasm) is most readily upset. The alteration of a few degrees of temperature, the application of too strong an electric current, or of certain substances denominated, from their effects, poisons, are sufficient to deprive this material of its vitality without producing any change in its structure or chemical composition that we can detect.

It is not unreasonable to contrast such phenomena with the magnetizing and demagnetizing of a bar of iron by an electric current, which it is generally agreed to consider as fundamentally consisting of alternations in the polarity of the molecules of the metal.

Another and more powerful argument in the same direction is the fact that the vitality of protoplasm is of limited duration. A portion of muscle can not go on contracting indefinitely; an epithelial cell can not continue to secrete for an unlimited time, and the powers of both these tissues are absolutely dependent on a due supply of food, thus bringing the animal or plant exactly on a par with a fire or lamp.

To some extent also the correlation of the physical forces finds an analogy in the common characteristics of the protoplasmic energies. While a nerve cell, muscle fiber, and gland cells all possess the power of self-restitution at the expense of food supplied to them by the blood, they differ markedly in the degree to which they manifest the properties of irritability and contractility, for, while the muscle displays this latter quality at its highest, the nerve and epithelial cells can scarcely be said to possess it, while they in their turn are subject to other series of molecular disturbances which liberate in the one case a nervous impulse, and in the other chemical energy. The study of the development of the fertilized ovum, when progressively with differentiation of structure is found specialization of function, would seem to point to a common nature for these forces of form, the difference in manifestation being dependent on the difference in apparatus (nerve cell, muscle, etc.) through which the force is liberated.

Although we can not pretend actually to demonstrate any correlation between the vital and physical energies, it is nevertheless instructive to notice some of the conditions under which the former are manifested. Prominent among these conditions is the fact that, when muscular contractility or nervous energy is manifested, there is a coincident production of heat and electricity in measurable quantity. And it is important to note that heat is not only an accompaniment of all vital processes, but it is also of absolute necessity that there should be a certain amount of heat present for such processes to be carried on.

We ourselves are not only producers of heat, but are entirely dependent upon a certain temperature for our existence. There is at least, then, a close interdependence, if not a correlation, of the vital and physical forces.

The progress of physiological investigation has referred many of the functions carried on in our bodies to purely physical causes. The important part played by elasticity in the movement of the blood, in expiration, and, to some extent, in muscular action; the permeability of the tissues to gases and fluids, which constitutes so large a share in the processes of nutrition, are all explained by physical laws: what I am here urging is, that the remaining factors of our living should be regarded from the same point of view.

The dependence of function on structure is now generally admitted, though not, perhaps, always remembered. That because such and such a tissue or organ has such and such a structure, gross or microscopic, therefore it manifests certain properties, is now about as generally accepted as the fact that because the wheels, spring, axles, etc., of which a watch is constructed are arranged in a certain defi-
nite way, therefore the watch goes; or, further, that because the steel spring has a certain molecular structure, therefore it is elastic. The importance of this admission is at once obvious when we come to treat of disease, itself a perversion of function dependent on some perversion of structure, which may or may not be apparent. No one doubts that the perfected action of a fatty degenerated heart is due to the replacement of the normal contractile muscle by a non-contractile substance—fat. And, though I admit in a large number of cases we can not detect the material changes in the tissues, we nevertheless are compelled to assume their existence, and look forward to their discovery, just as, fifty years ago, we might have hoped for the detection of fatty degeneration of muscle, which was then unknown.

With such a principle as this to guide us, you will see how entirely misleading it is to speak, as so many do, of "functional disease," implying thereby a perversion of function that has no material cause. All disease is functional; and if we accept function as the expression of a certain condition of structure, altered function must be due to some other condition of structure. I grant you this may be very minute, and, perhaps, at present not to be recognized by the best means at our command; but nevertheless it is there, and must be there, by the terms of our argument. If it be not so, then indeed will there be some special mystery surrounding living things, something unthinkable, and not to be investigated by us.

Nor can it be allowed that the dependence of function on structure is only true in certain cases and not in others; it must be wholly true or not at all; and so long as our present notions of the nature of force and matter hold, so long will it be necessary to accept only a material cause for vital activity, whether it be healthy or morbid.

A further value of maintaining this, which I would call a consistent view of physiology, is to be found in the possible explanation it affords of the mode of action of drugs. If the theory be accepted that vital phenomena are but forms of molecular motion, we shall be driven to explain the action of poisons, or other substances, brought in contact with the ultimate atoms of the tissues as an interference with their normal molecular vibration, and according to the extent and locality will be the results following these molecular lesions.

I know of but one phenomenon of living things which may not be expressed in terms in harmony with this theory of the ultimate nature of living matter, and that is what I would call the tendency to death. That it is common to all living things we are aware, but no plausible explanation of it has ever been given so far as I know. Yet, that all living things die in the course of time, does not seem to me to prevent the acceptance of the theory, though I can not begin to think why a material of a certain chemical composition, which manifests certain special properties, the expression, as we assume, of certain forms of molecular vibration, should of itself tend to cease manifesting such properties, the favorable conditions for their production remaining the same. I might, perhaps, imagine that molecules of matter could synthetically be arranged so as to vibrate in those planes which are expressed by contractility, though I know of nothing to show that this has been done. But I can not imagine why, when once these molecules are so arranged, and are maintained in suitable conditions, they should of themselves tend to depart from that special form of motion.

I have, I hope, gentlemen, said enough to warrant our adopting, at least provisionally, a purely physical basis for physiological phenomena, or, at all events, expressing these in terms that are used in reference to chemical and physical changes. The advantage of this must be obvious. It breaks down the unjustifiable barrier that has been erected between the investigation of living and non-living things, and allows a uniformity of procedure that is both scientific and desirable, and this without any assumption of the absolute truth of the principle. It may be that in time the whole of our notions of the atomic nature of matter, and the relationship of force to matter, may undergo an entire change; if so, the physiologist will be prepared to meet it, and adapt his views to the newer and more correct doctrines. But it will be easier for him to do so if he have already been in harmony with the chemist and the physicist, instead of groping wildly in the maze of vague notions and ill-defined terms, as is now too often the case. At any rate, it will be conceded that physiological investigation, conducted on these lines, may help to substantiate or disprove much that we now hold in reference to the nature of matter and force.

If what I have said to you to-day be sufficient to suggest such trains of thought as may lead you to this end, I am satisfied.

Original Communications.

THE INDICATIONS FOR HYSTERECTOMY.*

By William M. Polk, M.D.
Professor of Obstetrics and the Diseases of Women and Children in the Medical Department of the University of the City of New York; Gynecologist to Bellevue Hospital.

It is a well-established rule in surgery that so desperate an operation as Freund's is now acknowledged to be is not to be performed unless there exists reasonable hope of a permanent cure. In extirpation of the uterus a permanent cure becomes impossible the moment the pelvic glands become infected, they being so placed as to forbid any attempt at their removal. The immense number of lymphatics running from the uterus and their close connection with the pelvic glands make it almost a matter of certainty that in every case of cancer the latter speedily become infected. There is no question but that this implication may exist sometimes before the glands become enough enlarged to be recognized, so that in any given case it would be impossible for one to say with certainty that the disease was confined to the uterus merely because no indurations or enlargements were to be felt in the surrounding tissues.

* Being the substance of remarks made at a meeting of the New York Obstetrical Society, April 17, 1858.
In uterine cancer, the disease commonly begins at the cervix near the external os, and extends upward as well as outward. If, from the local and general conditions present, we had good reason to believe that the disease was confined to the cervix, and such was actually the case, amputation of the entire cervix, an operation comparatively safe and easy, is all that would be required. Should the disease have extended into the body, it would surely have reached the lymphatic glands, for the tonic required for the former is ample for the latter. Such cases would, therefore, be beyond any curative treatment, Freund's or other, palliation being all that is possible.

Touching the few cases of cancer which begin in the uterine body, it is simply a question as to the time of recognition. In the early stages they are regarded as instances of hypertrophy of the mucous membrane with what are called granulation formations; and as such are treated with the curette. Should such a case be recognized as cancer, before there was any decided enlargement of the uterine body, perhaps it would be fair to look upon it as one fit for Freund's operation, for prior to such enlargement the chances of glandular implication are remote. But, cases of primary cancer of the uterine body being comparatively rare, and their early recognition by no means easy, the opportunity for the operation in question, even here, is by no means common.

In sarcoma of the uterus the operation holds a strong position. In this disease glandular infection is far less rapid, the disease remaining localized longer than pure cancer, patients dying as often from septicemia and pyemia, resulting from the repeated efforts with the curette, as from the unmolested disease.

A large proportion of these cases can be recognized before glandular infection has occurred, even before there is any decided enlargement of the uterus; consequently, when everything is favorable not only for its operation, but for its early justification and cure. The disease, however, is very rare.

I may sum up by saying that in cancer of the cervix, the common form of uterine carcinoma, Freund's operation is contraindicated; for the disease, if local, can be eradicated by the amputation, if necessary, of the entire cervix, whereas, if glandular infection has occurred, a cure is impossible, palliative measures being then all that are justifiable. From this category I would exclude Freund's procedure, for it is, in my opinion, less useful and far more dangerous than a combination of the many now in vogue. In primary cancer of the body of the uterus it is justifiable, provided the diagnosis be made before glandular infection has occurred; but this is a difficult, and, in some instances, an impossible question to determine, and that too in a rare disease.

In sarcoma of the uterus it is fully justified, and the conditions calling for it can be determined with reasonable certainty, yet the disease is far from common. Consequently, the field open to the operation is very narrow.

ON CAUSES OF MELANCHOLIA.

BY GEORGE BAYLES, M. D.,
ORANGE, N. J.

(Concluded from page 175.)

When Providence interposes, as will often happen, to undo our best endeavors, we shall have lost something, but not all. Any wise and established conservative system will work the better as time rolls on. Every circumstance at the outset is liable to be adverse, but the element of time makes every correct principle stalwart and operative. There is much in our every-day life that tends to mortal decay. An ideal life for a pregnant woman will be one that furnishes the power to resist the manifold influences which tend to depreciate the original value of her developing fetal germ. Practical common sense will grant that that interesting state of woman—viz., pregnancy—may be made much safer than it usually is made for both mother and fetus. This safety, of course, under our present line of thought and limit of inquiry, concerns only undeviating and normally healthy development. We, therefore, inquire what are the aids to development, and what will tend to preserve the normal mental and nerve endowment of the fetal infant. Conception should have elements of comparative certainty and welcome expectancy not always experienced by cohabiting parties. The frame of the connubial mind should be approving and expectant.

Conception should invariably be legitimate—i.e., in matrimony—for it can not be that illicit connection in a civilized community will be free from perturbing anxiety. Unhallowed and fertile chance will be accompanied by mental disquietude if not with terror, and this is prejudicial, in the highest degree, to germ integrity. Conception should not occur by undesired accident, even under the most proper matrimonial relations. This variety of fruitful intercourse, under the most proper matrimonial relations, will, in its results, greatly resemble what follows from illegitimate and unhallowed sexual commerce. Conception during the practice of any form of "sexual fraud," and hence unexpected and greatly undesired, is likely to be fatal to the integrity of the germ through the often violent emotions of discontent and alarm experienced by the female.

Conception should occur under the thrilling influence of love and mutual respect of the parties having sexual relations of the nuptial order.

Satisfaction with any result that may be found as a sequence of the intimacy should characterize any event that may lead to conception.

Any shade of discontent of the male party should not be permitted to overshadow the hopefulness and happiness of the female. Tacit agreement as to possible results should characterize these proceedings, and this should be maintained under at least the semblance of mutual satisfaction. In brief, conception should be approached honestly as to purpose; it should be honorable—i.e., lawful—it should be a joy to all concerned. It should not be a disgraceful surprise, and it should not happen through failure of any pre
ventive measures so commonly and viciously resorted to in the midst of the most moral and well-conditioned communities. The most benign start that can be vouchsafed to the human germ will be, we believe, of incalculable advantage to the cunity thus segregated from the maternal matrix.

The starting of a human life, if possible, without any profound emotional disturbance assures the right inclination or bias. To maintain this initial tendency requires the continuance of wisdom and of good principle throughout the period of gestation. The comparatively voluntary nature of the influences supposed to be efficient in preserving healthy fetal life is a notable and interesting fact. It makes parental responsibility all the greater, and augments in an important degree the value of real judicious and sufficient professional guidance and quasi guardianship.

The period occupied from conception to parturition by the normal state of pregnancy ought to be among the most healthy and happy of the critical periods of female life. That it often is not so we are well aware. That it is sometimes characterized by exuberant health we have all observed. Very much depends upon the state of health preceding conception; not a little upon the conditions associated with conception, and, more than all, by the prevailing conditions associated with pregnancy. So direct are all the favorable and adverse circumstances in their influence upon the product of conception, that the state of pregnancy has more interest for us than it has been usual to acknowledge.

The formative period of a human being ought to be subject to influences that are tranquil, cheerful, and hopeful in their effect upon the mother. Agents ministering to physical comfort and mental peace (if not repose) ought to be abundant and unfailing.

The sort of ideal existence that a pregnant woman ought to be allowed to enjoy, to insure perfection of offspring, would not just now become us to inquire, because it is only attainable under extraordinary circumstances of great good sense, intelligent management, and ample means. Still, knowing that there is a standard, quite within the attainable, in some circles, we appreciate a state to work up to as circumstances permit.

How far short we fall of the ideal, or of that which it is possible to reach, the common every-day experience of the pregnant woman gives us deplorable examples. According to usual observation, it would almost seem to be a period of greatest suffering and inconvenience to the poor woman, not because of any local or general physical affliction, but because of the multiplication of cares, anxieties, burdens, sights, fears, and turmoil that crowd into this period in ordinary family life.

In the lower walks of life, is it not true that generally nothing is so unempt, slouchy, neglected, unambitious of the petty niceties and delights of existence, and sometimes so completely overlooked in the doxeties of their pleasures, as the pregnant woman? It would seem that the custom of this class so manifestly ignores the woman in the "family way" that she ignores herself. The honorable pre-eminence and glory of her peculiar state is not appreciated. Perhaps one reason is that it is of such frequent occurrence. She seeks comfort and moral support under every circumstance of discouragement.

This system of sorrowful subordination is found in every grade of society in varying degrees. The least harm it can do to the prospective mother is to create dejection or "lowness of spirits." The least harm it can do to the living entity within the uterus is to give a tone to its character tending to melancholia, or of some morbid cerebral function not limited by its own lifetime, but to be transmitted as a "queerness" to posterity through the line of its progeniture.

Heredity has laws regarding which we have some knowledge. To establish a wholesome pregnancy is the text of one of the great duties of our age. It contemplates the fairly good health of the parties about to become parents, the peaceful, happy home relations, the usual resources and domestic supplies unstinted, the usual cares of home or family judiciously lightened, or else cheerfully borne by others for the time; interesting and beneficial changes of occupation, amusement, and rest; unrestrained intercourse with generous, helpful friends, sufficient out-door exercise in every way that will contribute to pleasure of mind and body, and with preferred companionship; absolute banishment of discord and feud; the total absence of fright and dismay from any cause—in a word, as beautiful and happy a life during the term of pregnancy as can be attained.

To many persons of grosser composition, much that we would count as refinement and moral happiness would have no such aspect, and, therefore, would not be adopted as a source of comfort and gratification, were it ever so easy to obtain. So much graver the indictment against their ancestors. Still this is more apparent than real, as there is a natural craving in nearly every pregnant woman's soul for the kind of comfort and consolation we have depicted. These grosser natures are under a new spell when the impressions of approaching maternity are upon them. If ever they are susceptible to any kindly influences, it is just at this time. This lifting of the veil of grossness, stupidity, brutality, or moral degradation, is solely for the benefit of introducing some hallowed influences that will reach and, peradventure, rescue the offspring. Bring to bear, at such times, the sweet offices of neighborly charity, communion, and good fellowship, and a soul will be warped back into some semblance to human loveliness; and, more than that, the soul yet to be is saved from the direful effects of the insensibility or un impressibility usual with the parental nature. Among the very lowly and the abject poor or criminal classes, how directly this will apply! The experiment has been tried too often to be doubted. But its aggregation of blessings has not yet been estimated in the mental calculation of the social economist, and we think not by the majority of busy practitioners of medicine.

Does this bear upon nutrition or innutrition in relation to the etiology of melancholia? We think it can be shown that it does.

Emotional disturbances of a disagreeable nature interfere prejudicially if occurring at the moment that conception takes place. Emotional perturbations of a distressing nature will interfere with correct development of the forms
during pregnancy. The principal response in fetal life to the maternal disturbing emotional impression will be within the nervous system of the fetus. The response must be of the nature of an agitating impulse, a wave of increased animation, and a subsequent suspension. This suspension of action will be within the molecular realm of the nervous system, and presumably of the great nerve-center, the cerebrum. This suspension, though transitory, is of the nature of an arrest of nutritive stimulus and supply. This suspension signalizes the end of one continuous process and the beginning of another. The planes of relation of the old and the new processes may be, and most likely will be, unequal. One will be above and the other below. If the former were above the latter, the result would be depreciation, and if the arresting or suspending impulse were of a disturbing and unfavorable kind, then depreciation would be the almost inevitable result. The many selvedge-edges, so to speak, within the nervous organism of a turbulent fetal life would be an interesting study, if so minute a department of neuro-histological research were open to us. The duration of these periods of suspended nutritive action would be as curious a subject of study as would be the physical demonstration of their results that were possible. Measure the physical effects of a bad dream, a sudden terror, a depressing suspicion, an unexpected conviction of guilt, the sorrow of a great loss, or the malign impression of an insidious superstition, we can not.

We can not, therefore, estimate in any degree the volume of these effects transmitted through the nerve conduits of the gravid uterus. We may conceive, with reason, that they are relatively as prolonged and as profound as the original disturbing impression, and, by reason of the immature action of less highly organized and developed centers upon which the impression is expended, it may be much more prolonged, and much more profound. We think we shall come nearer the truth if we regard such as the fact.

If emotion of the mother, excessive in degree, is capable of suspending fetal cerebral nutrition, thereby deflecting the lines of normal healthful action, and thus converting a brain without primary functional faults into one with functional faults, perhaps full of such faults, what should we say of that variety of innutrition due directly to insufficient food or defective assimilation of nutriment in the pregnant female? This evil relates not so much to the hungry and ill-fed through poverty and an insufficient food-supply (though it includes many of earth's millions under these heads), but more especially to those who are practically starved because of some functional and temporary hindrances to right digestive processes.

Indigestion and mal-assimilation are the great and current evils of the day, and particularly with the pregnant woman.

Emotion, mechanical difficulties, and subacute nervous disorders in the pregnant greatly contribute to this malady, with all its baneful manifestations; but, nevertheless, from any cause, a stinted nutrition bears as directly, as continuously, and as effectively upon the well-being of the fetus.

We are inclined to attribute non-assimilation of food during the period of pregnancy, when not due to stinted food-supply, more to emotional disturbances than to any other cause. The importance, therefore, of controlling and guiding the emotional experiences of the woman during the period of pregnancy in relation to the question of fetal cerebral nutrition can not be overrated.

Emotion of the pronounced kind can directly arrest or suspend nutritive action in the nerve-centers of the fetus, or it can do this indirectly by an abridgment of nutritive elements. It generally does both at once, thus making the strength of one effect to re-enforce any possible weakness of the other. This dual action induces results that have come to be important enough to excite our serious consideration.

The kind of emotion capable of such extraordinary results within the organs of procreation is by no means a zephyr, or a trifling undulation of the ordinary current of mental sensitiveness.

Nevertheless, slight ebullitions of emotion are probably very potential in the direction under review.

Apprehensions, disappointments, disgusts, disgrace, wanton neglect and cruelties, will produce certain tempests of feeling known under the name of violent emotion that in their direct effect can reach the very depths.

Overwork, impiousness, social obscurity, and ostracism (in cases where these are bars to ambition), envy, physical weariness, and general discontent, may be regarded as very liable to create these rages of feeling that in the end are effective and so pernicious.

Seconding the remote predisposing cause—viz., emotion—we have, in every-day life, all the immediate or proximate exciting causes of nerve distruption during fetal life. As examples of these, we will mention the effects produced by certain diseases, by alcohol intemperately used, also excessive impressions from erethismus simplex to erethismus ebriumorum, the erethism of inordinate venery, or any other variety of neural exaltation. The agencies which accidentally combine with any personal tendency or idiosyncrasy to create strong pathogenetic neural impressions are various, and of a kind that generally come under the head of voluntary or acquired, and are, therefore, avoidable.

The generic term melancholia applies, then, according to our mode of reasoning and review of initial influences, to the sum of aberrations of nerve function developed from impaired and vitiated elemental nerve-forces. It is largely, if not wholly, an inherited dyscrasia, and the heritage depends chiefly, if not altogether, upon avoidable conditions and influences. Whether recent or starting many generations back, a wrong impulse has at some time been given that the benign efforts of nature have not been all to overrule. A brain inheriting normal and healthy conditions is never susceptible to motives of melancholia, excepting under the direct influence of acute organic disease. There are many forms of accidental disease that are capable of impairing nerve-health and inducing melancholia. Even these have less power when tendencies which are inherited are normal or nearer the standard of health, and these present better opportunities for prompt recovery. The great problem of the age is how to avert malign agencies that will undermine and vitiate the nerve power of infants,
THE PATHOLOGY OF
ACUTE LOBAR PNEUMONIA
FROM A NEW STANDPOINT.

By WILLIAM D. SCHUYLER, M. D.

Second Article.

Designation of the Disease; its Nosology and Histological Definition; Description of the Disease; its Essential Character; not an Inflammatory Disease; not essentially a Fever.

That there may be no misconception as to the form of this malady to which reference is made in this paper, I would especially designate it as that pneumonic disease which has the site of its primary lesion in the walls of the capillaries of the pulmonary stroma of the affected area, but which originates, according to Tanner and Bristowe, "in the lung substance," according to Niemeyer "in the air cells," according to Roberts "in the tissue of the lung," according to Wilson Fox (Reynolds's "System of Medicine") "in the vesicular structure of the lung," according to Jurgensen (von Ziemens's "Cyclopaedia") "in the alveoli and bronchioles," according to Delafeld "in the air vesicles and interstitial tissue," according to Aitken "in the true pulmonary tissue," and, according to Flint, "in the pulmonary substance or parenchyma in the air cells, and bronchioles."

While I agree with these authorities that the obvious seat of this malady is in the pulmonary stroma or parenchyma, yet, for reasons to be given hereafter, I would more definitely locate the initial lesion, as stated, in the walls of the capillaries of the affected area.

Nosologically, I would designate this most important disease as an acute lobar pneumonia, which title, while it has reference to the locality of the process, its extent, and the nature of the attack, does not limit the nature of the action.

Histologically, I shall show that the first event is a functional insufficiency of a certain number, few or many, of the pulmonary functional capillaries, which comprise a short segment of the systemic circulation; that the first result is a passive filling of these vessels, an obstruction to the systemic current, and an extension of the insufficiency through collateral action and pressure; that the second event which develops is an anatomical insufficiency of the capillaries first affected, resulting from extreme pressure, and that the second result, due to the latter insufficiency, is exudation or extravasation.

I shall treat, therefore, of acute lobar pneumonia the immediate origin of which is in the pulmonary capillary walls, the principal pathological features of which are, first, a functional obstruction of the systemic blood in its passage through the lungs; second, an exudation which consolidates the involved organ. Further, this malady is the acute pneumonia of the sporadic form met with in general practice, which develops with a sudden onset like a stroke, in which the involved pulmonary structure, from the fraction of an organ to an entire lung, or even more, undergoes a process of rapid solidification, with loss of function, but which immediately, and in a typical case such as we are con-
sidering, with equal rapidity again undergoes resolution by
softening and absorption of the solidifying mass, and at an
early day permits the lung to regain its normal condition,
with perfect renewal of its functions.

This pneumonia process is attended by a characteristic
fever, and general, well-marked functional disturbances.

The prominent features of the former, as depicted by
its temperature curve, are its sudden rise to its maximum
high point shortly after its onset; second, its equally rapid
and often more extensive decline when defervescence sets
in; third, its maintenance of a high elevation between these
two points. Again, as this curve often shows a late rise
just prior to its marked decline, and as the decline quite
frequently takes it to a point a degree or more below nor-
mal, these may be considered as others of its special char-
acteristics.

The symptoms denoting functional disturbances are:
difficult respiration, or marked dyspnea; difficult, hesitating
speech; a small, soft, empty pulse; arterial anemia; loss
of appetite; scanty urine; constipation; venous congestion;
an overworked right heart; nervous, especially men-
tal, depression.

The characteristic attendant symptoms are: a sharp,
short chill; sudden accession of fever; pain in the side, or
pulmonary, not constant, distress; persistent hacking, some-
times harsh, hard cough; a characteristic expectoration;
highly-colored, scanty urine; a skin at first hot and dry,
afterward bathed in profuse and persistent perspiration;
a herpetic eruption, not constant, about the mouth; cyanosed,
dark countenance; a bright hectic spot on the cheek; a
furred tongue; dark mucous membranes, especially of the
mouth, eyes, and tongue; mental anxiety; possibly mild
delirium; great restlessness; and evidence, as the disease
advances, of a rapidly developing asthenia.

These symptoms continue unchanged, or quite as fre-
quently increase in gravity up to the moment of defer-
vescence, when they singularly and specially abate, at which
time the patient experiences such relief that, notwithstanding
his markedly asthenic condition, he expresses himself
as well. The debility which results from an attack of this
malady is of so marked a character as to be worthy of no-
tice, especially as explaining a delay which, in many cases,
attends convalescence, and also as furnishing indications for
the treatment of the condition.

The duration of the malady is variously estimated at
from three to twelve days. Convalescence may be well in-
augurated as early as the fifth and generally by the tenth
day, or it may be delayed many days or even weeks longer.
I have met with cases where evidence of complete, localized
consolidation still existed at the end of two months, after
which restoration of a healthy condition of the lung and its
functions was established.

While the foregoing constitutes an outline sketch of the
course, symptoms, and duration of the malady, and while
its duration averages from seven to fourteen days, including
a safe convalescence as it occurs in a moderately robust sub-
ject, yet the events of which an attack is comprised vary as
to particulars, in every case or patient, as to character, ex-
tent, and duration. These variations are due to idiopathic
states, nutritive conditions, character of constitutional re-
ation, concurrent or causal conditions; to treatment, care,
and nursing; extent of lung involved, order and progress of
attack; and, lastly, are influenced by the inherent recuperative
powers of each individual patient.

What is the Essential Character of this Malady?
—From the literature of the subject up to the present time
we shall have no little difficulty in arriving at a satisfactory
answer to this question, on account of the various theories
therein set forth, the uncertainty of the deductions reached,
and especially on account of the fact that no theory set
forth is adequate to explain all or even some of the more
important phenomena of the process.

In the early days of medicine, it was described as a
peri-pneumonia, and then, as down to the present time, by
a majority of writers and practitioners, treated as an in-
flammation of the lung structure, or as an inflammatory
disease of the lungs. Within the past three decades or
thereabout, however, there has been shown a growing dis-
sent from this traditional view, and this notably among the
more prominent of the recent writers. This dissent has
developed out of considerations of the special charac-
teristics of the phenomena which make up the process, and of
their unlikeness to the events which are comprised in or
make up acknowledged inflammatory diseases, and an ina-
ibility to explain these phenomena upon a simple inflamma-
tory basis unaided by other hypothesis. This dissent is
further strengthened by the following facts: (a) That the
malady, uninfluenced by treatment, and under favorable cir-
cumstances, is proved to be a self-limited affection; (b) that
its attendant pyrexia pursues a cyclical course, and is char-
acterized by an almost pathognomonic temperature curve;
(c) that there is a seeming want of relation between the
local lesion and the constitutional symptoms; and (d) that
the local lesion does not result from causes which excite in-
flammations in general and in other structures. On account
of these characteristics and other facts to be presented, a
simple inflammatory basis has been abandoned by some,
and an increasing number, as not affording an adequate ex-
planation for the phenomena presented.

But, because of the etiological obscurity which has en-
veloped the genesis of the disease, on account of the orderly
character and progress of its development, from the dis-
tinctive characters of its pyrexia, before alluded to; be-
cause the disease embodies well-marked constitutional fea-
tures on the one hand, and an equally not less pronounced
characteristic lesion on the other; because there is no exact
conformity of the former to the extent of the latter; because
of the dangers and sudden death which may occur at any
stage of the malady, and which are not satisfactorily ac-
counted for by the extent of the local lesion; and because
of the generally concealed negative effects of treatment upon
the progress of the local lesion—from the likeness of these
characteristics to similar characteristics of the infectious
maladies, from the general resemblance of the constitutional
manifestations of acute lobar pneumonia to those of the
infectious fevers, though they are not strictly similar, this
malady has been termed by the dissentients a constitutional
infectious disease, an essential fever, and likened to ty-
phoid fever, cerebro-spinal meningitis, small-pox, or acute articular rheumatism. In other words, it has been characterized as a special fever, due to a constitutional m  a b i s w o r b i , a blood-poison, with a local pulmonary lesion, which is pathologically similar to the intestinal lesion of the solitary and agminated glands in typhoid fever.

While some argue that a specific poison, m a t e r i e s m o r b i , is essential for the production of this fever, others hold that many and different poisons may cause its development.

Furthermore, besides those who still regard and treat acute lobar pneumonia upon the old view that it is a local inflammatory disease (and they comprise a majority of physicians), and, second, those who hold that it is a constitutional affection, an essential or infectious fever with a local lesion, there is a third class, who, while they believe the inflammatory theory inadequate, do not entirely accept the hypothesis that the disease is a specific fever, although they attribute the pathological state to the action of a constitutional poison.

All medical men without exception, so far as I am aware, hold and treat the local affection, the pulmonary process, as an inflammation of a croupous or fibrinous character.

A general view, then, such as has been summarized, of this pathological process establishes the remarkable fact that, at this time, this common and most important of all diseases, a disease which every practising physician is called upon to treat, whose characteristics are most strongly marked, whose ravages are felt in every quarter of the habitable globe, whose effects even in our own city are most fatal, and at times with surprising suddenness—a disease which terminates more active valuable lives than any other malady, and which affects the lower animals as well as man—that this disease, so far as its essential nature or true character is concerned, is still sub judice, not settled, but unknown.

Although the statement that pneumonia is essentially an unknown disease will strike many as remarkable if not unwarranted, yet it has the support of no less an authority than Wilson Fox, who, writing in Reynolds's "System of Medicine," says, "The pathogenesis of acute primary pneumonia is involved in considerable doubt and obscurity, and has been the subject of much discussion." And further he refers in the margin to the lectures of Dr. Parkes ("Med. Times and Gazette," 1860) as illustrating the point, and as showing that at that time, twenty years ago and upward, the old view of the disease was deemed unsatisfactory by many, and that a discussion as to its nature had been carried on—namely, as to whether it was a local inflammation or a constitutional fever. Upon this subject the author just referred to says: "Two opposite theories have been advanced respecting its origin, both of which are supported by certain facts and opposed by others." He thereupon gives the two hypotheses regarding its nature as set forth—the constitutional, fibrile, or specific on the one hand, and the local or inflammatory on the other—and adds: "The second hypothesis as such appears to be scarcely a tenable one, and even the first appears to require some modification. This statement briefly characterizes the present status of the subject, and sets forth the unsettled conditions of belief entertained in regard to it by medical men."

The supporters of these views, first, that pneumonia is a local disease, simply an inflammation of the lungs, and that the attendant and constitutional phenomena are its consequences, are Aitken, Tanner, Watson, Bartholow, Niemeyer, and others; second, that it is a constitutional malady, an infectious fever, is supported by Flint and Juergensen.

As we have seen, while he advocates a constitutional infectious character for the disease, Wilson Fox does not clearly subscribe to either hypothesis offered, and Loomis ("Med. Record," vol. xix, p. 413, "Discussion of Sanders's Paper") adopts the latter view. He does "not believe pneumonia to be a local disease, nor was he prepared to regard it as a specific constitutional disease with a local lesion. He preferred to occupy a middle ground, that pneumonia, like many other inflammations, may be developed by a variety of poisons."

The prominent advocates of the constitutional febrile hypothesis are Professor Flint, of our own city, and Juergensen (von Ziemssen's "Cyclopædia"), of Tubingen.

I can best set forth this view in their language. Professor Flint ("Principles and Practice of Medicine," edition of 1861) says: "The view now taken of the pathological character of the disease differs from that presented in previous editions of this work, and is not yet generally entertained by medical writers and practitioners. Acute lobar pneumonitis in the nosological systems of the present, as of past time, is placed among the local diseases, and, in regard to certain questions, it has been regarded as the type of a purely inflammatory affection. This view of its pathological character I hold to be erroneous. The pulmonary affection is doubtless inflammatory, but it is the local manifestation or the anatomical characteristic of a febrile disease, sustaining to the latter a relation analogous to that which the affection of the solitary and agminated glands sustains to typhoid fever. If this doctrine be true," says this author, "the proper place for this disease in the nosology is among the essential fevers." Professor Flint attributes the enunciation of this doctrine in this country to Dr. William H. Draper, who set it forth "in a paper read before the New York Academy of Medicine in 1866, and published in the Bulletin of that year." As already referred to, Dr. Parkes discussed the point quite fully in England in 1860. His remarks were published in the "Med. Times and Gazette" of February 25th of that year.

As Juergen sen's formulary (von Ziemssen's "Cyclopædia") for this hypothesis is strongly put, I give it entire. He says: "Croupous pneumonia is a constitutional disease, and is not dependent upon a local cause. The pulmonary inflammation is merely the chief symptom, and the morbid phenomena are not due to the local affection. The hypothesis of a morbid cause is indisputable. Croupous pneumonia belongs to the class of infectious diseases."

From the fact that this view, the constitutional infection, has much to commend it and is fast gaining ground, I justify myself for giving it at length. But, in regard to the nature, essential character, and..."
pathogenesis of this disease, I now venture to express the opinion that the facts which exist when fully considered do not sustain either hypothesis set forth. Nor do they justify general teaching that the local affection is an inflammatory process. Furthermore, on the contrary, I shall suggest in this paper for the nature and character of the pathological process of acute pneumonia, an action totally different from any heretofore promulgated, the truth of which I shall show is maintained by all the related facts.

I am not unmindful of the importance of the negative position here assumed in regard to existing theories as to the essential character of the malady, nor of the seemingly well-grounded opposition I must encounter in advocating a non-inflammatory character for the local affection, but I shall show that the facts to be deduced justify the assumption.

First, acute lobar pneumonia is not an inflammatory disease; because it is unlike inflammatory diseases aetologically—in regard to frequency, to locality, and in the time of its occurrence; it is also unlike them in the mode of its accession, manner of development, nature of local process; in its exudation, course of exudation, and in its consequences. Of its unlikeness to inflammatory diseases in general, Jürgensen says: "The inflammatory diseases (including under this general name pericarditis, pleuritis, laryngitis, cephalitis, hepatitis, peritonitis, gastritis, and enteritis) present annual ranges which are very different from those of pneumonia, and vary but little in frequency from year to year." This shows a general causal coincidence. The author referred to makes the foregoing statement from an analysis or comparison of von Ziemssen's of the "London Mortality Reports for the years from 1840 to 1850," in which he also finds that the diseases more closely related to pneumonia anatomically, bronchitis and pleurisy, do not coincide in point of time with that malady.

Further, in regard to the former, bronchitis, an inflammatory disease, in which the structure involved may be regarded as comprising a portion of the pulmonary stroma Jürgensen says: "This malady, like catarrh, increases in frequency the farther we advance from the tropics to the higher latitudes; this is not the case with pneumonia, which occurs in all degrees of latitude, and does not seem to be more frequent in one than another." But, to this last general fact there may be exceptions; for, as regards the disease in our own country, Dr. Flint says, "It is vastly more frequent in the Southern than the Northern States." The temporal causes of these three diseases are unlike. According to all observers, pneumonia is most frequent in mid-winter and spring, while bronchitis, though most frequent in spring, yet with pleurisy prevails more generally than pneumonia throughout the year.

It is also unlike all inflammatory disease in its more direct mode of accession. It is always developed directly, irrespective of extrinsic agencies. It does not result from contiguous inflammations, not even from pleurisy or bronchitis, which structurally may be considered as inflammation of the pulmonary stroma; nor from empyema nor gangrene, and it is not produced by contusions or penetrating wounds (Flint). In the rapidity of its development to the formation of an extensive consolidation, in the amount of its exudate, which may be from two to four pounds (Flint), in the completeness and even character of consolidation throughout the affected area, in the transient character of the consolidation, and in its complete removal, leaving the lung structurally and functionally intact; in the tendency of this process to attack a certain portion of the lungs, the lower lobes, and especially the lower lobe of the right lung; and in its compact, not diffuse, mode of extension, possibly to a second, and in a certain proportion of cases to a third lobe—it manifests laws of development, course, and effect, which are dissimilar to those of a simple inflammatory disease, and which "are suggestive of a constitutional cause" (Flint).

Another dissimilarity of this malady to the inflammatory diseases is found in a want of relation of its general symptoms to the local lesion. "In pneumonia an extensive consolidation may be attended with a slight fever, while, on the contrary, a small consolidation may be attended with high fever and severe general symptoms" (Jürgensen); while in inflammations in general it is the rule that a certain grade of intensity of constitutional or general symptoms indicates the character and extent of the local lesion, and governs the prognosis in the case. The fact that there is no general relation between the local and constitutional symptoms in pneumonia is well known. Nevertheless, this observation is true in a general way—I hold that in individual cases, or idiosyncratically, such relation does exist.

Furthermore, as pneumonia cannot be produced by any of the usual causes of inflammation, however strong or weak their action (Jürgensen), as it does not conform to the laws of inflammatory diseases in its course, being self-limited, while they are the reverse; nor in the character of its temperature curve, which instead resembles those of the infectious fevers; as it shows little or no tendency to relapse, while relapses are common in inflammations; as after a pneumonic process, the patient, as stated, beyond being singularly exhausted (considering the brief duration of the active stage), is well; and, lastly, as, unlike the resulting state after a general inflammatory disease, there are no effects beyond debility, which prolong convalescence—it should not be classed with these maladies. The foregoing affords abundant reason for rejecting the theory that acute lobar pneumonia is an inflammatory disease.

Is acute lobar pneumonia essentially a fever, a specific infectious disease, with a local lesion, due to a specific blood-poison (Jürgensen, Flint), or to one of many poisons (Wilson Fox, Loomis, Draper)? And is the local affection, the pulmonary event, only a result of the constitutional disease (Jürgensen), a conservative process by which a "matrice morbi" is eliminated from the system (Draper)? Furthermore, is the disease a pathological process similar to the infectious fevers—namely, typhus, typhoid, the intermittent, the exanthemata, arthritic rheumatism, or epidemic cerebrospinal meningitis?

As stated, a careful examination of all the related facts, in the opinion of the writer, does not justify an affirmative conclusion.

But, in order to reach a sound deduction upon this
point, we must hear and examine what the adherents of the pyrexial hypothesis have to say in its support.

(To be continued.)

LETTER FROM VIENNA.

The Facilitates for Summer Work in Vienna.—The Iodoform Treatment of Wounds.—The Removal of Lymphatic Glands from the Neck.—The Lying-in Service.—Tracheotomy.—The Rapacity of Assistants.

Vienna, August 1, 1883.

Probably most of your readers suppose that Vienna during the summer vacation can present but few attractions for the medical student; yet I can testify that this is the time when some of the best and hardest work is done. An American arriving here in midsummer is met by the discouraging statement that he has come at the wrong season, that there is nothing to learn, and that he will do better to go away and return in the autumn. I am convinced that this is an erroneous idea, and would most earnestly advise those of my countrymen who can spare only two or three months in the summer for medical study abroad, to spend that time here. The courses are not crowded, the material is sufficient, and the instruction is little inferior to that given during the semesters. For one especially interested in obstetrics, this season of the year is particularly favorable, since there is not now ganz eine Epidemie von Praktikanten, as a German tersely expressed it. With the delightfully cool weather which we have thus far enjoyed, I can not imagine any surroundings more inducive to earnest work than the shady alleys and breezy wards of the Krankenhaus.

In Billroth's clinic (conducted during the summer by his second assistant, V. Hacker) it is noticeable how strictly antiseptic details are carried out, even in minor operations. The spray is entirely dispensed with, except in peritoneal surgery, when it is used for an hour before (but not during) the operation, absolute cleanliness being enforced on the part of the assistant. Iodoform gauze seems to be the favorite dressing, and drainage-tubes are used even in superficial wounds. Deep wounds are packed with the gauze, which is not removed for several days. It is asserted that the danger of iodoform poisoning is reduced to a minimum when the drug is used in this way. I am unable to state what the percentage of recoveries is under this routine treatment, but have been informed that the results are quite favorable. A favorite operation this summer seems to be the removal of enlarged lymphatic glands from the neck, even in cases when they cause no mechanical obstruction. It would be difficult in America to persuade a patient to undergo a long and dangerous operation, involving, perhaps, the ligatures of large vessels, and eventually an unsightly scar, when no question either of life or of comfort was concerned. This is unquestionably a surgical concession to the modern theory of the origin of tuberculosis.

As before stated, one's time may be spent most profitably in the lying-in wards at this time of the year. The system of perfect cleanliness which prevails is attended by gratifying results. Professor Carl Braun kindly showed me his report, extending over a period of four months, and including one thousand cases of midwifery, with only two deaths—one from placenta previa, and another from eclampsia. In Spaeth's wards during the same period there were no deaths. Such statistics are indeed surprising when one considers the large number of difficult and instrumental labors which occur here, and the fact that the women are constantly being examined by men in daily contact with the calverer.

An occasional visit to the St. Anna's Children's Hospital is not without profit. I was able to observe several cases of tracheotomy there, and noticed that in each instance the operation was performed earlier than with us. The percentage of recovery is about 30 or 40.

The number of American students at present in Vienna is small, as they seem to have adopted the popular idea and wait till autumn before coming. One only needs to be here a few days in order to become convinced of the truth of the reports which he has received at home in regard to the growing capacity (to use a term not too strong) of the average Vienna assistant. The tendency to shorten the courses and increase the fees offers an alarming prospect for the student of the future. Unless I am greatly mistaken in regard to the expressions of dissatisfaction which I hear universally from Americans who have been long studying here, the time is coming when the increasing clinical facilities of our own larger medical centers, and the greater courtesy, not to say conscientiousness, of our instructors, will render foreign medical study less fashionable than it used to be. Certainly the opportunities for post-graduate work in New York are not to be despised even now, in comparison with those of Vienna.
THE PHYSIOLOGY OF SLEEP.

As regards the vascular condition of the cerebrum during natural sleep, there seems to be at present a virtual agreement among physiologists. Whatever views may be held of the immediate or proximate cause, it is generally admitted that during sleep the brain is relatively anemic. There are well-attested facts enough on record to substantiate this. The brain, demuded of a portion of its cranial covering, has been carefully watched during the waking state and in sleep, and it has been ascertained that, both in man and in the lower animals, the organ is comparatively bloodless during sleep, and its circulation more sluggish than at other times.

In the early part of this century Blumenthal first enunciated this theory, and supported it by the interesting case of a patient who had lost a portion of the right frontal bone; during sleep the brain was seen to be anemic and in a collapsed condition. Dendy * relates a similar case, which was observed in 1821. But Durham's memoir on the physiology of sleep, which was published in the volume of "Guy's Hospital Reports" for 1860, was the first really thorough and scientific contribution to our knowledge of the vascular state of the encephalon during sleep, and the relation of that state to the phenomena of sleep. To Hammond also, many of whose experiments were made prior to Durham's publication, we are indebted for numerous original observations, and for the most exhaustive and conclusive exposition of the subject yet given to the world. †

We may say that during sleep all the encephalic blood-vessels are under a diminished pressure, as proved in fact by the manometer, and that this lessening of the active flow corresponds with a diminution of cerebral function. Even if no experiments had ever been made, inductive reasoning would have led irresistibly to this conclusion. During the intervals of digestion the gastric mucous membrane is relatively pale and bloodless; the submaxillary gland does not become turgid with blood until it begins to secrete saliva; a muscle in action becomes markedly hyperemic. It is so with the organs in general. The performance of function is characterized by vascular activity and fullness. If in any part there is a call for work, there is a call for more blood. The nervous system forms no exception to this law, and there is the most intimate and absolute correlation between the evolution of nervous energy and the activity of the circulation. So true is this that it is everywhere admitted that the induction of functional work in any such apparatus as the digestive, the sexual, or the muscular, produces a degree of hyperemia of the apparatus called into action sufficient to prove a serious hindrance to the easy and satisfactory performance of any severe mental task.

Professor Mosso, of Turin, has lately made some interesting experiments on persons who had lost portions of the cranial bones, using Marey's ingenious hydro-sphygmograph. Noting, like others before him, that during sleep the brain diminished in volume, with shrinkage of its blood-vessels, and that the livelv blush characterizing its surface during the waking state disappeared, he observed also that any sudden impression, if sufficient to rouse the brain to partial activity, was sure to be attended with an increase of its vascularity and its volume. He has proved, too, that every effort of the intellect is normally accompanied by a diminution of volume in the peripheral parts, the arm, for example, and that, on the contrary, when the cerebral activity is lessened the distant members are augmented in volume. Sleep is always accompanied by a dilatation of the vessels of the extremities, and particularly of the forearm, where this dilatation has repeatedly been measured by Mosso with his registering apparatus. Every excitation from without causes a contraction of the vessels of the forearm of the sleeping subject, and the augmented blood pressure at once produces a renewed influx of blood to the brain. In this manner the fluctuations of cerebral activity can be followed: a sound, a touch, a ray of light falling on the closed lid of the sleeper, all give rise to modifications of the cerebral circulation—unperceived, doubtless, but possibly the source of dreams.*

The immediate cause of sleep is not simply the shutting off of a portion of the blood current from the brain. There are more important factors. Here Vulpius ‡ is right. The lessening of the blood supply to the encephalon is rather the accompaniment than the cause of sleep. We can not produce normal sleep in a person simply by exsanguinating his brain, or else we should have in an ice-cap and a hot-foot-bath the speediest and most effective of hypnotics. The brain must first be in a certain condition. There must be in the constitution of the supreme nerve-centers something that forbids further activity, and with that cessation of activity there will be a lessening of the blood-flow to the brain, in accordance with the physiological law before stated. What is the particular modification of the cortical cells which renders them less fit for the liberation of their special forces, and finally compels a suspension of action, with a diminution of the blood supply? Herbert Spencer has given a very plausible explanation, in accordance with the theory of evolution:

The waste of the nerve-centers having become such that the stimuli received from the external world no longer suffice to call forth from them adequate discharges, there results a diminished impulse to those internal organs which subserve nervous activity, including more especially the heart. Consequently, the nerve-centers, already working feebly, are supplied with less blood and begin to work more feebly, re-

* "The Philosophy of Mystery," London, 1841; cited by Hammond in his work on "Insanity."
† See articles by Dr. Hammond in this journal for 1865 and in the "Journal of Psychological Medicine" for 1866, also his "Sleep and its Derangements," Philadelphia, 1872, and his "Treatise on Insanity," New York, 1883.
spending still less to impressions, and discharge still less to the heart. And so the two act and react until there is reached a state of profound unimpressibility and inactivity. Between this state and the waking state the essential distinction is great reduction of waste, which falls so low that the rate of repair exceeds it. ... During the day the loss is greater than the gain, whereas during the night the gain is diminished by scarcely any loss. Hence results accumulation; there is restoration of nerve-tissue to its state of integrity.

According to Mr. Spencer, that rhythmical variation in nervous activity which we see in sleep and waking is the result of adaptation, due to survival of the fittest. "An animal so constituted that waste and repair were balanced from moment to moment throughout the twenty-four hours would, other things equal, be overcome by an enemy or competitor that could evolve greater energy during the hours when light facilitates action, at the expense of being less energetic during the hours of darkness and concealment." *

With some qualification, the foregoing statement is about as satisfactory as any that has yet been offered as to the proximate cause of sleep. During the waking hours the vaso-motor center in the medulla is doubtless under inhibition by the superior centers, and there is relative relaxation of the cerebral arterioles, with dilatation of the capillaries; when the cells of the hemispheres are exhausted, they are no longer able to exercise this inhibition—in common parlance, they no longer powerfully attract the blood—and the vaso-motor center "puts on the brakes"; the blood supply is then no longer sufficient for function, though enough for nutrition.

An ingenious theory has lately been proposed by Preyer, of Jenais,† according to which, to use a homely illustration, the fire ceases to burn because the flues are clogged with cinders.

As Preyer puts it, the activity of the cerebrum is a sort of respiration, while its repose is a sort of asphyxia of this organ. It is certain that every psychical act, every thought, involves a certain consumption of oxygen by the nervous substance. During waking, this gas is furnished to the brain in the blood. If the blood supply fails, those forms of activity which we denominate consciousness, attention, volition, and thought, cease. This is easily proven by compression of the carotids. It is known that in the waking hours the muscles, as well as the nerves and the nerve-centers, as a consequence of that activity, produce substances easily oxidizable, among which is lactic acid. Some have even attributed the sense of fatigue which we experience after prolonged exertion to the presence of this acid in the blood.‡ According to Preyer, after the work of the day is done, and the quiet of sleep is sought, the waste materials of which we have spoken, and which he proposes to call proteines (substances which cause fatigue), being accumulated in the tissues, little by little undergo decomposition, by taking oxygen from the blood. They thus divert a considerable quantity of this gas from the cerebrum, the cells of which, deprived of this element so indispensable to their activity, enter into a state of relative repose. These waste matters are, then, the physical cause of sleep, which will be the more profound and prolonged the more the blood is charged with the excremenitious products of function. Preyer has experimented on animals by injecting varying quantities of lactic acid into their blood, and has produced a deep somnolent condition which could not be distinguished from natural sleep. The use of lactate of sodium in the human subject has sometimes been attended with a like hypnotic effect. Further researches are needed before the question can be considered as settled.

THE CINCINNATI BOARD OF HEALTH.

Boards of health have been made up of queer material before now, but we confess to some surprise at the picture that the "Cincinnati Medical News" draws of a board recently created by the Common Council of that city. It is composed of nine persons, every one of whom, except one, a medical specialist, is a saloon-keeper—as our contemporary vigorously phrases it, a "beer-jerker." It seems that the Common Council had once before appointed a board of health, but that its composition was so vile that the Legislature abolished it, and authorized the Superior Court of the city to appoint a health officer. The failure of the court to make the appointment left the city without any sanitary official, and furnished an occasion for the Common Council to give fresh proof of its utter disregard of decency by creating the present board. The Chamber of Commerce has been led to move in the matter, and there is a fair prospect that the newly appointed board will be declared illegal, on the ground that the Common Council had no authority to create a board of health.

The journal from which our information is derived adds that the fault is with the citizens, who choose to ignore their political duties, and allow their prerogatives to be usurped and turned against them by a horde of "bummers." This is undoubtedly true, and not of Cincinnati only, but of almost every large city in the country as well. The sanitary branch of a municipal government is apt to prove a particularly easy prey to the corromaratus termed politicians, owing mainly, it must be supposed, to the fact that the community at large look upon health officials as rather ornamental than useful, and hence care little into whose hands the offices fall. No doubt a smart visitation of pestilence would disperse this delusion in Cincinnati, as well as elsewhere, but our recent history does not encourage any great confidence that even such forced enlightenment is likely to prove lasting.

THE QUESTION OF QUARANTINE.

It is getting to be the fashion in some quarters to decry the practice of quarantine. Whether this tendency is to be taken as a surrender to the greed of trade, or as another flowering of Anglophilism, it is not easy to determine; nor is it profitable to speculate as to which of the two interpretations would cast the less discredit on those professed sanitarians who are continually emphasizing the need of cleanliness, as if that covered the whole field of sanitation. As a matter of fact, our sanitary officials do as a rule carry out all known measures looking to
the preservation of the public health to as full an extent as their limited authority and resources will allow of. Further than that, many of them conduct investigations that are of great value to preventive medicine. It is strange, therefore, that, whenever it comes to the matter of addressing the public, they so often choose the part of making it appear that sanitation is little more than scientific scavenging.

The President of the Board of Health of the State of Louisiana lately issued a proclamation, seconded by another from the Governor of the State, which, although stringent in the matter of quarantining arrivals off the city of New Orleans, we can not but regard as amply justified in all its details, in view of the threatening aspect of yellow fever on the Gulf, and of its repeated ravages in New Orleans. Our contemporary, the "Santarian," however, looks upon the terms of the proclamation as inhuman, and intimates that the rescue of an infected ship's company is a most important part of the beneficent work of modern sanitation. No doubt this is true, but, when it comes to the point that one or the other of two interests must give way—that of a limited number of persons on shipboard, already exposed to infection, or that of a great center of population—the terms that seem hard in President Jones's proclamation must be acknowledged as humane in their ultimate operation.

As for the action of the Health Officer of the Port of New York, who, as we recorded last week, lately took pains to inform a commercial organization that articles of merchandise might be so stored in ships carrying other goods from infected ports as not to call for their detention by quarantine, we can only look upon it as playing with fire, providing our understanding of his proposition is correct. In the face of such a disease as yellow fever, an efficient quarantine deserves more confidence than all other measures put together, and public opinion should not allow any laxity in its enforcement.

A GRADATION IN HONORS.

The distinction of knighthood was graciously offered to a Dublin physician lately, but he declined to receive it. In view of the freedom with which the title of baronet has been bestowed upon members of the British medical profession of late, it is gratifying to observe that several of our English contemporaries applaud the Irish practitioner for refusing the lesser compliment, intimating that under the circumstances the offer looked like little less than an insult to the profession in Dublin. But now the "Spectator," chronicling the bestowal of baronetcies upon Dr. Andrew Clark and Mr. Prescott Hewett, gives signs of a rare talent for stoking a cat the wrong way when it says that "this will make the medical profession in Dublin still more angry," and that, when the Dublin men can produce a physician and a surgeon who have done as much as Dr. Clark and Mr. Hewett, it trusts "that they, too, will receive baronetcies."

Dr. Clark, says the "Spectator," is undoubtedly quite at the head of his profession, and, if he had done nothing else, the service he has rendered in persuading middle-aged men and women not to over-eat themselves, and in showing them how much less food and wine and tea they ought to take than they actually do take, is one quite inestimable, and deserves a certain ethical as well as medical recognition." From this we learn that the conferring of a baronetcy is an ethical recognition, and we are left to infer that there is some difference between a man's over-eating and his over-eating himself! If Dr. Clark has really contributed so powerfully toward preventing the depopulation of England as to have persuaded the men and women of that country, whether middle-aged or not, not to "over-eat themselves," the most rancorous of Dublin doctors will scarcely grudge him his baronetcy.

MINOR PARAGRAPHS.

THE FOOT AND MOUTH DISEASE.

While he was of the opinion that the American quarantine system gave no security against the conveyance of the disease by persons attached to the quarantine stations, and by articles taken from the yards, Mr. Dodson recently stated in the British House of Commons, in reply to an inquiry, that it was an un doubted fact that the foot and mouth disease had been carried from England to America—thus confirming the statements made by the United States Treasury Cattle Commission, a summary of which we gave last week. He added that certain Canadian cattle now suffering from the disease at Bristol had been in contact with infected animals from Ireland at Liverpool. We understand that the veterinarians of Canada absolutely deny the existence of the disease in the Dominion. The Collector a Boston has made a report to the Treasury Department in regard to increasing the accommodations at that port for the quarantine of imported cattle. He says that the agricultural buildings and grounds at Concord, Mass., can be secured as a cattle station at an annual rental of $1,000, and that they can be put in condition for the service at an estimated expense of $4,000. These quarters will accommodate 560 head of cattle. The collector also says that he has received notice of the expected arrival of 360 head of cattle in the first week of September.

A CASE OF ALLEGED MALPRACTICE.

The husband of a lady who died suddenly in New York on the 23d of July, while under the care of Dr. George W. Brooks, is now represented by the newspapers as entertaining a suspicion that the death was due to the effects of the medicines employed, and as about to take measures to ascertain the cause of death. The deceased was a daughter of Signor Susini, the singer, and the wife of a Dr. Hunter, who removed to New York from Detroit not long ago. According to Dr. Hunter's statements, as given in the newspapers, Dr. Brooks first prescribed some pills of ergotin, "macrotin" (a term applied by the "eclceities" to an impure resinous precipitate obtained by adding water to a saturated tincture of cinchicqusa), and resin of podedophyllin. This was on the 15th of July. Twenty-one of the pills were taken in the course of a week, and on the 22d of the month Dr. Brooks ordered a liquid preparation—what it was, Dr. Hunter does not know—to be given in thirty-drop doses at 1.20, 3.20, and 7.20 p. m. The lady went to bed rather earlier than usual that night, and woke her husband at about three o'clock in the morning, asking for a drink of water. Half an hour afterward the husband awoke suddenly, found his wife gasping, and in a few seconds perceived that she was dead. Dr. Brooks was sent for, and on his arrival ordered a hot bath. The husband avers that Dr. Brooks poured the remainder of the medicine into the sink, and
MINOR PARAGRAPHS.

put the bottle into his pocket. Being asked his opinion as to the cause of death, he answered, "apoplexy," but, this being received with incredulity, said: "Well, call it cerebro-spinal meningitis." "You change your diagnosis quickly," the husband retorted; "and then," his statement continues, "we went through the horrible farce of placing a dead woman in the bath which had been prepared." The only additional statement of any importance is, that Dr. Brooks advised the husband not to have a post-mortem examination made on the arrival of the remains at Detroit.

Dr. Hunter states that it was this advice, given at the time the body was about to be sent to Detroit, that aroused his suspicions, and yet he must have entertained a sentiment akin to suspicion when he made his sharp criticism of Dr. Brooks's diagnostic accomplishments. Moreover, he did not have an autopsy made on the arrival of the body at Detroit, and he allowed considerable time to elapse before making the matter public. It is evident that a good deal of allowance must be made for the husband's perturbed state of mind. Dr. Brooks's name is not given in the "Medical Register," but he is registered at the County Clerk's office as a graduate of the Medical Department of the University of the City of New York.

CONTAGIOUS PLEURO-PNEUMONIA AMONG CATTLE IN CONNECTICUT.

Last April a resident of the town of Salem, Conn., bought a cow in Jersey City. Whether the cow was recently imported does not appear. She was taken to Salem, and early in July pleuro-pneumonia appeared among the owner's cattle, and on an adjoining farm, causing three deaths in the herd first attacked, and one in the other herd. Both herds are now isolated, and a few of the animals are still suffering from the disease. The lungs of the dead cattle have been examined by Professor Llaurald, of New York, and by Dr. Rice, of Hartford, a veterinarian, who have pronounced the disease to be "lung plague." A representative of the Treasury Department Cattle Commission has lately visited the farms, and the department does not apprehend a spread of the disease beyond its present limits.

THE HEALTH OF BOSTON.

From the Eleventh Annual Report of the Board of Health of the City of Boston we learn that during the year 1882 there was a decrease in the total number of deaths from zymotic diseases, notwithstanding the increase of population, and that the percentage of deaths from all causes was smaller than in any other year since 1874. As the board remark, this is a most gratifying exhibit, and speaks well for the comparative sanitary condition of the city. It is especially satisfactory to observe a marked decrease in the number of deaths from diptheria, and in the proportion of deaths to the number of cases. There were only eight deaths from small-pox. Relief from the sewer stench that at times proceeds from the Charles River, the Back Bay, the South Bay, and some other localities, is not to be hoped for, the board state, until the great sewer is completed that is to take the sewage out to sea, and they very properly urge the prosecution of the work of building it with the utmost speed.

THE CHICAGO SMALL-POX MORTALITY FOR THE YEAR 1882.

By the Report of the Department of Health of the City of Chicago, recently published, it appears that during the year 1882 small-pox caused 1,292 deaths, a number greatly in excess of that set down to any of the other zymotic diseases except "diarrheal diseases," which latter caused 1,387 deaths. In view of the well-nigh absolute certainty with which small-pox may be prevented, this cannot be called a creditable showing.

THE ILLINOIS METHOD OF DEALING WITH QUACKS.

According to an Illinois newspaper, one James I. Lightfall, known also as "Kansas Jim," "Rustic Jack," and the "Indian Medicine Man," lately made a visit to Illinois, where, by resorting to various catchpenny devices in the way of shows, he managed to do a thriving business for a time extracting teeth and selling "Indian" remedies. He sought to evade the vigilance of the State Board of Health by taking into his employ a practitioner who had been licensed by the board. On complaint of some citizens of Decatur, however, the employee's license was revoked by the board, and Lightfall was put under bond of $500 for trial. Having filed his bond, he at once proceeded to resume his "practice," but, having learned that another action was to be brought against him, involving another bond of the same amount, he concluded to leave for a different field.

THE ASHES AND GARBAGE NUISANCE.

The new President of the Board of Health of the city of New York is commended by the newspapers for having, as it is said, taken measures to enforce the ordinance requiring ashes and garbage to be placed in proper receptacles. If he will compel the thorough and systematic removal of the ashes and garbage, without much regard to the receptacles, he will deserve still greater praise.

DISGUISED TIPPLES.

It is reported from Washington that the Commissioner of Internal Revenue, suspecting Hostetter's Bitters to be a tipple disguised as a medicine, has been confirmed in his suspicion by the report of a Government chemist to whom a specimen of the nostrum was submitted for analysis. The commissioner says that when the mixture is sold as a beverage a license must be paid, but when sold in good faith as a medicine none will be required.

A CURIOUS FOREIGN BODY IN THE THROAT.

A Philadelphia surgeon recently found a bent and barbed piece of wire in a patient's throat, and at first took it to be a fish-hook. After it was removed, however, it proved to be what is known as a meat tack, resembling a double-pointed carpet tack, with both points barbed. It seems that butchers of Chicago beef use these tacks for fastening tags to meat, the points being driven into the meat by means of a blow with a hammer.

"PHYSIO-MEDICALISM."

"The Physio-Medical Journal," published in Indianapolis, complains that "physio-medicalism," whatever that may be, has not been given representation in the Missouri State Board of Health; and it calls upon the individuals of the sect to organize. "To secure our rights, maintain our principles, protect ourselves, become a power in the land, and establish scientific medicine," it says, "we must have organization."

THE "ANNALES DES MALADIES DES ORGANES GENITO-URINAIRES."

This is the title of a new monthly journal, several numbers of which have reached us. The last number, for July, contains the following original communications: 1. A clinical lecture
on Bleomorrhagic Inflammations of the Urachus, by Professor Guyon. 2. The conclusion of an article on Hydro-lummocele from Rupture of the Tunic Vaginalis, by Professor Reverdin. 3. Rapid Epithelioinvasion Degeneration of Fistulous Tracts following Urachal Stricture, by M. E. Guinard. A number of clinical records, abstracts, etc., are also given. From the numbers issued thus far, the new journal must be characterized as of a high degree of excellence. It is edited by M. E. Delellus, under the direction of M. Guyon, Lancereaux, and Méhu, and published in Paris, by J.-B. Bailliére et Fils.

THE ATLANTIC JOURNAL OF MEDICINE.

The first number of this new monthly journal, dated August, 1883, has reached us, and we find it highly meritorious. The number contains two important communicated articles—

A Review of the United States Pharmacopoeia, by J. N. Willis, Esq., and a paper on Typhlitis and Perityphlitis, by Dr. R. B. Stover, both of which were read before the Richmond Academy of Medicine. These are followed by a number of selections and several well-written editorials. The journal is owned and edited by Dr. Robert B. Stover and Dr. Henry G. Houston, and published in Richmond, Va. It is announced that each number will contain sixty-four pages of reading matter. The first number exceeds the promise, for it contains seventy-six. We cordially welcome the new journal.

THE AMERICAN PSYCHOLOGICAL JOURNAL.

This is the title of a new quarterly journal issued by the National Association for the Protection of the Insane and the Prevention of Insanity. It is edited by Dr. Joseph Parrish, of Burlington, N. J., with Dr. C. L. Dana, of New York, Miss A. A. Chevalier, of Boston, Dr. W. W. Godding, of Washington, Dr. H. H. Bannister, of Kankakee, Ill., and Dr. J. C. Shaw, of Brooklyn, as associate editors; and published by the Messrs. Blakiston, of Philadelphia.

Two numbers, of 112 pages each, have been issued, and, so far as we can judge from their contents and from the mechanical make-up, the journal can not fail to prove a creditable exponent of the cause to which it is devoted.

FATAL EFFECTS FROM THE BEE'S STING.

The "Nashville Journal of Medicine and Surgery" quotes a paragraph with this title from our issue of July 7th (crediting it, by the way, to the "Medical Record"), and adds the following from the "Southern Medical Record": "The editor of this journal is cognizant of a case of death resulting from the sting of a bee. In this case, however, there was evidently an idiosyncrasy, as the same party had narrowly escaped death on a former occasion from the same cause."

THE "MARSHALLTOWN MEDICAL REVIEW."

A specimen copy of this "quarterly publication of materia medica and therapeutics" has reached us. It contains nine pages of reading matter, including an editorial article on eucalyptol and an original communication on eucalyptol. Three of the six advertising pages are devoted to Sander & Sons' eucalyptol, and the journal is edited by M. Sander, M. D. The subscription price is $1 per annum; single copy, 50 cents. Marshalltown is in Iowa.

THE RISKS OF MASSAGE.

In a recent number of the "British Medical Journal," Dr. Julius Althaus, of London, cautions his readers against the indiscriminate use of massage. He quotes Busch, of Berlin, as recommending it chievily in the treatment of deformities and of muscular pain, and adds his own impression that it can do good only in superficial affections. He has known it to do palpable harm in cases of disease of the central nervous system.

NEWS ITEMS.

Infectious Diseases in New York.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 21, 1883:

Yellow Fever.—The most important event connected with the progress of the disease that has happened since the account given in our last issue was made up is our outbreak in the Navy Yard at Pensacola. This was announced on Thursday of last week in a dispatch from Surgeon Owen to the Attign Secretary of the Navy. Up to Thursday of this week there had been eight cases, with three deaths, no new cases having been reported during the forty-eight hours preceding that date. The outbreak occurred among a detachment of marines on guard duty at the yard, and prompt and well-directed measures were taken to seclude that force, with the object of preventing the spread of the disease to the naval forces or to the civil population. On Wednesday of this week, however, a house-to-house inspection ordered by the Surgeon-General of the Marine-Hospital Service revealed two cases in a sailor's boarding-house in the town. The patients were at once removed to the quarantine station, and the house and its contents were fumigated and surrounded by a guard. Surgeon Owen is among the sufferers, and we regret to have to announce that the latest advice represents his condition as critical. Assistant Surgeon William Martin was at once ordered to his assistance from New Orleans, together with a physician from civil life, Dr. Hargis. The Commandant requested a court of inquiry into the origin of the outbreak. A court was accordingly ordered, and convened on Wednesday. The detail includes Assistant Surgeon Martin.

On Thursday of last week a ship that had been infected with the disease was allowed to come up to port at Quebec, having landed her sick sailors and been disinfected at the quarantine station. It has been asserted in Galveston that at least one case of yellow fever has occurred in New Orleans, and that the sanitary officials of that city invariably try to conceal the fact when the fever does appear there.

The Captain-General of Cuba has ordered all vessels leaving Cuban ports to provide themselves with bills of health from the local sanitary boards. Therefore, vessels coming from Cuba to this country will require two bills of health, as our Government recognizes only those issued by our consuls. This course on the part of the Captain-General looks like a mere grasping for fees.

Cases have been reported from Tampico and Panama during the past week. In Vera Cruz there were 477 deaths from the disease in the month of July.

Cholera.—The mortality from the disease in Egypt has abated steadily during the week, but a few cases are reported from Beyrut, in Syria. A man is said to have died in Quebec...
last week from "Canadian cholera." The "Medical Times and Gazette," of London, learns that, in view of the possibility of an outbreak of cholera in Paris, 480,000 f. have been voted for building wooden hospitals in the bastions of the fortifications, to serve ultimately for patients with other infectious diseases.

SMALL-POX. Of a very malignant type is reported to the Surgeon-General of the Marine-Hospital Service as extensively prevalent at Tamanul and Purificacion, Mexico, and in Guatemala.

ACCULERATED TEA. The Government announces its determination not to allow of the importation of tea containing more than eight per cent. of extraneous matter. Six hundred packages of Japanese "tea dust" were lately rejected by the Government Examiner.

A CONNECTICUT PHYSICIAN IN DISGRACE.—Dr. John J. Griffin, of Hartford, is stated to have evaded arrest last week by resorting to flight. A warrant had been issued for his apprehension on a charge of bastardy and attempted abortion, preferred by a girl who professes to have been wronged by him on the occasion of her having called at his office for medical advice. As there is nothing to show that the doctor was aware of the legal action that had been taken, there is some ground for the hope that his absence may yet be explained as having no connection with the charge.

THE NORRISTOWN ASYLUM HOMICIDE CASE.—In the case of James Gaffey, the attendant charged with having caused the death of a Mr. Fiss by a brutal assault, a preliminary hearing had been held in Norristown last week, and Dr. Chase, of the asylum, testified that Mr. Fiss died of pyemia, the consequence of a broken jaw.

THE CHILDREN'S HOSPITAL, BOSTON, will hereafter receive patients under fourteen years of age who are sent to a hospital by the city authorities on account of injuries, such patients having heretofore been sent to the City Hospital.

A HOSPITAL AT NORTH ADAMS, MASS.—The town has appropriated $15,000 for the purpose of building a hospital, and the plans for the building are said to have met with the approval of Dr. Alfred L. Loomis and Dr. William M. Polk, of New York, to whom they were submitted.

Dr. C. H. Cogswell has been appointed Assistant Port Physician at Boston.

OBITUARY NOTES.

HOMER BOSTWICK, L. M. S. S. N. Y., died at his house in New York on Tuesday, the 14th inst., at the age of seventy-seven. In 1830 he came to New York from Ohio, his native State, and in 1837 he received a license to practice from the Medical Society of the State of New York. Several years ago he published a large work on venereal diseases, illustrated with colored plates. For a number of years he served with credit as colonel of a militia regiment. He was a member of the Medical Society of the County of New York.

ARTHUR D. EDGECOMB, M. D., of Lancing, Mass.—Dr. Edgecomb, who was a Brunswick graduate, died on the 9th inst., in his sixty-fourth year. He was born in Livermore, Me., and practiced in several towns in Maine until 1874, when he went to Lancaster. His death was due to Bright's disease.

GEORGE G. TUCKER, M. D., of Westfield, Mass.—Dr. Tucker died suddenly on the morning of Monday, the 29th inst., in his forty-seventh year. He was born in Warren, Mass., in 1834, and was graduated from the Medical Department of Howard University in 1855, having been for two years house-
ing to pursue this difficult study. The weather reports of the signal office and his own, or the daily observations of others, have enabled him, from time to time, to relate these to his record of neuralgia, and by this method he has avoided the constant presence of daily thought as to what was about to happen in consequence of atmospheric changes. I may add that I never knew any man more free from unwholesome attention to his own ailments. Most of what I learned from our former study still stands unaltered by this much longer record; but there have been some fresh and suggestive gains in the relation of pain to meals, to daily barometric changes, and to magnetic conditions. The diagrams are readily understood in connection with explanations given in the text, except those for the months of November and December, 1877, which we have given as an illustration of the method of study, and of the obvious relation of storms to pain.

The following is the report of the case for the past seven years, made by Captain Catlin:

![Diagram](image-url)
For the year 1872 there were 1,783 hours of pain (the records for 1873 and 1874 are incomplete); for 1875 there were 1,892 hours; for 1876, 1,790 hours; for 1877, 1,794 hours; for 1878, 1,591 hours; for 1879, 1,535 hours; for 1880, 1,567 hours; for 1881, 1,463 hours; and for 1882, 1,370 hours. From 1872 the annual amount of pain increased, and probably reached its maximum in 1874, a year of high pressure, which, as we proceed, will be found to have some relation to the pain. (See Table, Fig. 2.)

For 1875 we have the highest recorded amount of pain (Fig. 3.) The next year, 1876, the amount of pain fell off to 1,600 hours, with a decrease of the mean annual pressure, equal to 00.021 of an inch, with corresponding increase of temperature.

For the year 1878 there was a remarkable lessening of 200 hours in the neuralgic amount, but, by following up the barometric curve, an equally remarkable fall is found. The annual mean of the barometer for the year 1878 was 00.098 of an inch below the mean of the previous year, and 00.067 of an inch below the mean for the eight years, the mean for the eight years being 29.916.* From the low annual pressure of this year we may almost infer a high annual temperature, which we do indeed

* For these barometric records I am under obligations to Professor Daniel Draper, Director of the Observatory at Central Park, New York.
This law of relationship of low pressure and high temperature to amount of pain, and the number of attacks of pain, and number of storms, will become more apparent when we come to the consideration of the quarterly and monthly distribution of pain and storm. Since 1878 the pain has diminished at the rate of forty hours annually, diminution being accelerated by a decrease of mean annual pressure and retarded (or actually held in suspension, as in 1880) by an increasing pressure. Making allowance for the annual decrease of pain, there is a remarkable parallelism between the pain and pressure curve. The yearly temperature bears the same relation to the barometer as it was found to have in the monthly fluctuations. The total amount of pain for the eight years ending January 1, 1883, was 12,944 hours, or nearly one fifth of the time. The distribution of the pain is shown by Fig. 4, 1, which is the curve of the total monthly amounts for the eight years. It will be readily seen that the winter months hold the advantage as pain-producers, and that for this period while the sun was north of the equator there were 6,788 hours, against 6,151 hours while it was south of the equator.

Of the quarterly amounts, the first quarter, beginning with the winter solstice, leads with 3,538 hours, followed by the fourth quarter at 3,245 hours; then the second, with 3,098, and the least in the third quarter (July, August, and September) with 3,003 hours.

Of the monthly amounts, March holds the lead, closely pressed by January, and in order of amounts follow: November, December, May, February, April, August, October, September, July, and June. The number of storms (Fig. 4, II) recorded for the eight years is 806, taken from the Signal Bureau Records.

Of this number, 529 belong to the winters, against 307 for the summers.

The quarterly numbers, in like manner, correspond to quarterly amounts of neuralgia, and by a reference to the storm curve (Fig. 4, II) there is shown a remarkable parallelism throughout with the pain curve.
The average duration (Fig. 4, III) of each attack of pain for the whole time was 18.97 hours; but again we find average duration bearing a relation to amount of pain and number of storms.

The average for the first quarter was 20.1 hours, for the second quarter 18.4 hours, for the third quarter 17.9 hours, and for the fourth quarter 19.4 hours, which we see is directly proportional to storm and amount of pain. The average duration of pain was found to be greatest in February; 20.8 hours, one of the coldest, if not the coldest month, and containing probably the greatest barometric fluctuations of any month in the year.

Although the average velocity of translation of the winter storms be greater than the summer ones, owing to their much greater range and power, they are farther reaching, and, in consequence, produce longer attacks. The hottest month of the year (July) gave the least average duration of pain, being seventeen hours.

The following table gives the full record for years and months of the amount of pain in hours:

This is a month of low average pressure and unimportant and minimum barometric fluctuations. By an examination of the curve of the mean monthly number of attacks (Fig. 4, III) there is found an almost exact monthly parallelism with the pain and storm curve, but the mean quarterly of the curve would not be as nearly parallel with the mean quarterly of the pain or storm, which shows that the number of attacks of pain is greater in proportion to the number of storms for summer than for winter. Many of the summer storms are difficult to trace, and some are not charted owing to their indefiniteness, but they are, nevertheless, pain-producers. For this reason it is believed that the relationship of the number of pain attacks to the number of storms is not as disproportionate as appears in the quarterly comparison of the curves.

Passing to the rain curve (Fig. 4, IV), we find it in harmony with the pain and storm curves, except for a few of the summer months. For these months, owing to the short and heavy precipitation of rain, and local character of many of the storms, the curve does not subordinate itself to the pain, storm, or even barometric curve.

Thus we see that rain-fall of itself is only relatively to be used as a measure for pain.

The barometric curve (Fig. 4, V), as it swings almost a curve from January to December, measures, with the storm curve, much more accurately the ordinates of the pain curve; and here we have reappearing in the quarterly and monthly products of neuralgia the law already disclosed in the annual product of pain, viz.: high temperature, low barometer, favorable for non-product of pain; and, in addition, minimum barometric undulations, favoring diminution of pain duration.

(To be concluded.)

NEW YORK OBSTETRICAL SOCIETY.

A STATED meeting was held April 17, 1883, Dr. C. C. Lee, President, in the chair.

The minutes of the previous meeting were read by the secretary, and were approved.

DIPHTHERIA.—Dr. E. L. Partridge presented the trachea and larynx, the seat of diphtheritic exudation, removed post mortem from a child who died, at the age of eighteen months, at the Nursery and Child's Hospital. He gave the following history: The child's previous health was good; it was well nourished. On the morning of March 24, 1883, the temperature was 100°F.; there was croupy cough, and croupy breathing on inspiration and expiration. During the day the laryngeal symptoms increased. There was no vomiting nor depression; food was taken; no membrane was visible. Temperature in the evening 100°. On the twenty-fifth, a. m., temperature 100°, pulse 120, respiration 40. Laryngeal symptoms were more marked. In the afternoon the temperature was 99°, the pulse 120, respiration 42. Though vomiting was occasionally provoked, no membrane was seen. The child was restless during the night; respiration was more troubled. On the morning of the 26th the temperature was 99°, the pulse 140, respiration 42. Up to this time there had been no symptoms of importance except those pertaining to the larynx. It was even thought that catarrhal laryngitis might be the disease present. But the child now began to pick at its throat; the skin grew cyanosed; restlessness was very marked. At 12.30 p. m. the symptoms were so serious as to demand tracheotomy. The operation was attended with but little hemorrhage. The pulse after the operation was 160, fair in quality, and soon fell to 144, remaining strong during the day. In the evening the temperature rose to 104°; dyspnea increased; the lungs became somewhat congested. Large pieces of membrane were coughed up through the tube. At 7.30 p. m. there was impending suffocation. Convulsions occurred, and death took place at 8 p. m.

At the autopsy, the lungs were found to be much congested,
with partial collapse and purulent bronchitis. The heart was normal, the liver was soft and pale, and the mesenteric glands were enlarged. Throughout the entire course of the disease there had been no ocular demonstration of a false membrane except that which was coughed out through the tracheotomy tube. But at the autopsy the larynx showed very distinctly a false membrane extending from the epiglottis to the bifurcation of the trachea, a lesion which could in no way be distinguished from that always seen in recognized diphtheria. Microscopical examination, made by Dr. Livingston, showed that the membrane consisted of conglutted fibrin, in the meshes of which were round cells of various sizes, and that the specimen presented all the characteristics of diphtheritic membrane. On reviewing the history, it would be seen that there had been almost entire absence of constitutional symptoms, the temperature being only 98° to 100° until an hour or two before death; the pulse strong throughout the course of the disease. There had been no indications of systemic depression, as from toxemia; no membrane could be seen. The laryngeal symptoms were marked from the first. There was a history, therefore, of so-called membranous croup, while the autopsy showed a lesion of the larynx which could in no way be distinguished from that always seen in recognized diphtheria.

Freund's Operation for Extirpation of the Uterus.—Dr. B. F. Dawson presented the uterus removed by Freund's operation, about twelve days before, from a woman fifty-one years of age, for cancer of the cervix. He first saw the patient about five weeks previously, when she was in very poor condition from loss of blood. The curette and the cautery had been used several times by himself and Dr. Keune, her regular attendant. with the result of checking the considerable hemorrhage; notwithstanding all treatment, the patient was rapidly growing worse, and was anxious to have a radical operation performed. Careful examination showed that the disease was not limited to the cervix, but extended up to the body, yet no involvement of the neighboring lymphatics could be discovered. The operation was very tedious, and required two hours and forty minutes for its performance, but no accident occurred, except the wounding of a small vein, which was readily secured, and no unusual difficulties were encountered. The patient took ether badly, but at the end of the operation rallied, and it was believed that she stood a fair chance to recover. A chance took place, however, and she died at the end of seven hours, evidently of shock. The speaker said that, in looking back upon the difficulties of this operation, the length of time required for its performance, the disemboiling requisite, the long abdominal incision, and the consequent danger to the life of the patient from shock, he felt convinced that it was an operation which should seldom if ever be undertaken, and he regretted that in the present instance he did not do the vaginal operation instead. Examination of the specimen showed the disease extending above the os internum.

Dr. P. F. Mundé was glad to hear Dr. Dawson, after having had personal experience with Freund's operation, speak of it in terms of disapproval. He himself, he was pleased to say, had never had any personal experience with it, although he had witnessed its performance at the hands of others. The length of time required to do the operation, the amount of shock attending and following it, and the few chances of immediate or permanent recovery, made Freund's operation one which should seldom be undertaken in gynecological surgery; indeed, in his opinion, it was one which should be entirely tabooed. If total extirpation of the uterus were indicated and feasible, he could hardly imagine a case where the vaginal operation would not be preferable to that of hysterotomy. The operation as performed by Billroth, Schröder, and Czerny—of re-moving the diseased portion alone, when confined to the cervix, by a wedge-shaped excision—subjected the patient to much less risk of life from the operation itself.

The President concurred in the views expressed by Dr. Mundé, and said that he had been very much impressed by the indications for the operation made by Dr. Polk, which he arrived at after a previous meeting of the society, as described at the previous consideration. An operation of such severity as Freund's had proved to be, he believed should not be undertaken for a disease which, should the patient recover from the immediate effects of the operation, would almost certainly recur within a year or two. He had witnessed the operation in four cases, and in each instance the patient died within forty-eight hours. Certainly, where the cancerous growth involved only the cervix, the operation for removal of the diseased tissue alone, as suggested by Dr. Mundé, was the one which was indicated. This operation, which had frequently been performed by Dr. Emmet and others, gave present relief, and did not involve danger to life. Should hemorrhage occur, it could be controlled by drawing down the cervix firmly, and carrying a wire suture behind the bleeding vessel, as in the manner indicated by Dr. Emmet.

Dr. W. R. Gillette asked whether any of the members present had had any experience with the operation described by Dr. Sims a few years since in an article in the "American Journal of Obstetrics," that of removing as much of the diseased cervical tissue as possible with the curette and scissors, and then applying chloride of zinc, causing the remainder of the diseased tissue to come away in a slough. He had resorted to this method in a number of cases, both in hospital and private practice, and had found it of decided temporary benefit. The last case in which he had used it was that of a patient who lived in Greenpoint, in whom the disease did not extend higher than the os internum. She was greatly enemiated, cachectic, had had frequent hemorrhages, and was looked upon as a dying woman. He cauterized the diseased tissue, and then applied absorbent cotton saturated with the chloride-of-zinc solution, of the strength recommended by Dr. Sims, and after nine days a slough came away, leaving a perfectly healthy looking raw surface. The patient afterward greatly improved, and no longer presented the constance of one suffering from malignant disease. Some weeks afterward slight hemorrhage recurred, and the operation was repeated. It could not be expected that the measure would prove more palliative. In one case, however, he saw the patient two years afterward, and not a trace of the disease had returned. Serious hemorrhage during the operation had occurred in but a single instance, in which it was controlled by the use of the tissue forceps.

The President referred to the method recommended by Dr. Noeggerath, of cauterizing the diseased tissue with the galvanic cautery, and subsequently, as often as granulations rose up, removing them with strong mineral acids. By this means it was believed that epithelium in the cervix could always be controlled.

Dr. Mundé had employed the method described by Dr. Gillette in numerous cases, with good results. In one case the patient was in an extremely low condition, and was expected to die of septicæmia within a week. The improvement was so great after the operation that one could hardly recognize her. Secondary hemorrhage had occurred in but one case, which had already been reported to the society. He believed that the danger from this source was less after the use of chloride of zinc than after that of actual cautery. Recently he had had a case in which he thoroughly seared the surface of an epithelium of the cervix; all oozing ceased, a tampon was applied, but he was called up in the night on account of secondary hemorrhage. The raw surface left by the slough from the chloride of
zinc application rarely heals over by healthy granulation, although every effort should be made to attain that end.

Dr. W. M. CHAMBERLIN had had the same good effect temporarily upon carcinoma of the cervix uteri by the application of the zinc-chloride solution; it had never been followed by secondary hemorrhage. He had, however, been troubled somewhat in making the application by the difficulty in preventing the escharotic coming in contact with the vaginal mucous membrane and leading to an eschar.

Dr. MUNK described the method of applying the zinc chloride as proposed by Dr. Sims, which was a perfectly safe one.

Dr. W. M. POLK expressed his views with regard to the proper indications for hysterectomy, in remarks which will be found on page 201.

SECONDARY HEMORRHAGE AFTER OPERATION FOR LACERATION OF THE CERVIX UTERI.—Dr. F. P. MUNK related the following cases: The first case was that of a patient in whom he sewed up a lacerated cervix and perinnium, and did Stolz's operation for cystocele. Catgut sutures were used on the cervix only. Arterial hemorrhage occurred from one vessel, but was checked by the sutures. Six days later, profuse hemorrhage occurred from the vagina, which undoubtedly came from the cervix, necessitating the use of hot alum-water, and finally ice-water and vinegar, which arrested the bleeding. Had this not been done, it must have become necessary to tear open the perinnium and tampon the vagina. Removal of the stitches subsequently showed that union had taken place.

The second case was that of a private patient, upon whom he repaired the lacerated cervix without any particular difficulty. While inserting a suture, an exposed pulsating artery was noticed. Eight silver-wire sutures were introduced. On the fifth day, the same day on which secondary hemorrhage occurred in the first case, he was called to see this patient, and found arterial hemorrhage so profuse that, after vainly endeavoring to check the bleeding by compressing the whole cervix with pince hemostatiques, he found himself compelled to hastily tampon the vagina with flat alum tampons, whereupon, fortunately, hemorrhage was arrested. Probably the artery referred to had been gradually cut into by one of the wire sutures.

The blood gushed from the external os. The sutures had since been removed, and the cervix found perfectly united. He wished to refer, first, to the danger of secondary hemorrhage after trachelorrhaphy, and, second, to this recurrence as a counter-indication to doing both the perinnial and cervical operation at the same sitting.

FIRST COITUS ATTENDED BY EXTENSIVE LACERATION OF THE WALL OF THE VAGINA, AND FOLLOWED BY PROFUSE HEMORRHAGE.—Dr. MUNK was called yesterday to see a girl, twenty-two years of age, whom he found pallid and anemic from the loss of blood. She had been married the night before, and but a single connection had taken place. It was not attended by severe pain nor by immediate hemorrhage, but some hours afterward she observed bleeding from the vagina, and sent for a physician, who gave ergot, but without benefit. He made no examination. Then another physician put ice into the vagina, but also without stopping the hemorrhage. Dr. MUNK examined the hymen for the source of the bleeding, but found that it came from a point higher up. Introducing a Sims's speculum, the vagina was seen to be ruptured on the right side for a distance of about two inches and a half, extending from one inch above the intima into the right fornix. The uterus was retroverted. He assumed that there was a disproportion between the male and the female organ. The bleeding was checked by firm tamponade with cotton. Two years ago he had attended a case of profuse hemorrhage from rupture of the hymen up into the vagina along the urethra during first coitus, in which tamponade also was required to check the bleeding.

Henry J. GARRIGIES, M.D.,
B. F. DAVISON, M.D.,
Frank P. Foster, M.D., ex officio,
Committee on Publication.

PATHOLOGICAL SOCIETY OF PHILADELPHIA.

A STATED MEETING was held March 22, 1888, the President, Dr. James Tyson, in the chair.

CHONDROMA OF THE SKULL.—Dr. J. P. COOKE GRIFFITH exhibited the specimen. The patient, aged twenty-nine, had been admitted to the Presbyterian Hospital, Philadelphia, June 10th. He was and had been suffering from persistent and very severe frontal headache, and held his head thrown back upon his shoulders to the farthest extent. Examination revealed a tumor of the size of a walnut upon the anterior portion of the vault of the skull. This had been recognized by the patient for from one month and a half to three months and a half. Just how long was uncertain, as his headaches were very much confused. He had suffered from headaches for twelve years. Ophthalmoscopic examination revealed double choked discs.

While in the house the tumor grew with great rapidity, and a new growth sprang up beside it. The larger one became soft and tender in spots. The patient became delirious, but coma and paralysis developed only three days before death, nineteen days after admission. The post-mortem examination revealed a large tumor upon the anterior portion of the vault, and consisting of a soft, red mass, but full of bone spicules, and to the right and connected with it a smaller, dense, hard, white growth. Apparently distinct capsules inclosed and separated the two. The periosteum covered both tumors. The entire growth was irregularly oval, four inches and a half long by four to five broad, and with one inch and a half for its greatest thickness. Removal of the calvaria showed that the greater part of the tumor was internal. Here it was divided into three lobules, of which two resembled the larger tumor in structure, while the bird was more like the smaller external growth. The dura mater covered the internal projection. At points it was attached to the brain, and bone spicules penetrated into the brain substance. The length of the entire internal growth was four inches and a half, width four inches, and the greatest depression upon the brain two inches.

The tables of the skull within the tumor were destroyed, and the bone around the edge eroded for some distance. The brain structure did not appear to be altered. Microscopical examination showed it to be a reticular chondroma, with a large amount of imperfectly fibrillated and rather translucent connective tissue, forming small meshes in which were cells; some embryonic, but very many cartilage cells. The bone spicules were evidently newly formed, and the older tumor had evidently undergone an ossifying metamorphosis, and then had become vascularized, forming a soft mass, in which the spicules were imbedded. Clinically, the case was of interest, from the existence of so great a depression of the brain with so few signs of disturbance of its functions.

Dr. WETHERELL asked what was the condition of the lymphatic system: were the glands enlarged?

Dr. GRIFFITH replied that only the post-cervical were affected.

Dr. FORMAD had examined the sections about a year ago; it was true, as he says, the predominant cells were those which resemble those of fibro-cartilage. There were, however, many young cells—cells like giant-cells; but the majority of the sections had more the appearance of fibro-cartilage. The conclu-
sion to which Drs. Tyson and Formal came at the time was that it was one of the varieties of chondroma. As the specimen appears now, it is too soft for chondroma, but seems rather to be a chondro-sarcoma. This would point the rapid growth and age of the patient. It is certainly not gummatus.

Metastatic Pneumonia following a Pistol-shot Wound of the Temporal Bone.—Dr. H. M. Fisher spoke as follows: The patient, H. G., aged twenty-six, from whom the specimens I present to-night were taken, was admitted to Dr. Lewis's wards, at the Pennsylvania Hospital, October 31, 1882, suffering from a pistol-shot wound of the right ear. The following clinical notes of the case were kindly furnished to me by Dr. J. H. Wills, resident surgeon to the hospital.

Examination of the wound with the Nélaton probe showed that the ball had passed through the posterior wall of the external auditory canal, and was firmly imbedded in bone about one inch from its point of entrance. The seat of the ball was distinctly marked by the marking of the lead on the porcelain of the Nélaton probe.

A prolonged effort to extract the ball was deemed advisable on account of its close proximity to the lateral sinus. On account of the inflammatory edema of the tissues around the wound, poultices were applied. Ptosis of the right lid and slight depression of the right corner of the mouth was noticed.

The patient remained in the hospital four weeks, during which time his general health appeared fairly good. He was permitted to go out on a pass, returned the following day with well-marked pleuro-pneumonia, and died ten days later.

The autopsy showed that the ball had penetrated the tympanic cavity and passed into the jugular fossa, where it was found imbedded. There was marked periostitis in the neighborhood of the wound, but no inflammation of the walls of the lateral sinus, nor of the internal jugular vein, was noticed.

I am inclined to believe that the infarcts found in the lungs and pleura owed their origin to numerous small thrombi that had been formed in the diploë of the petrous portion of the temporal bone, the venules of the diploë having become plugged as a result of the periostal inflammation. These thrombi, becoming loosened in consequence of increased blood pressure, were washed out into one some of the adjacent sinuses, and so into the pulmonary venous circulation. The case is, I think, an interesting one, as showing the dangers attendant upon such injuries to the temporal bone, apart from any incidental injury to the brain or its membranes.

Sections of the heart, liver, spleen, and kidneys showed marked amyloid infiltration of these organs. Whether such marked changes could be induced in all these organs in the short period that elapsed from the receipt of the injury to the date of the patient's death is a question I would leave to other members of the society to decide. At any rate, so far as I could ascertain, no previous history of suppuration was elicited from the patient during the time of his sojourn in the hospital.

Appended are the notes of the microscopic examination of the different organs.

Lungs.—Vessels everywhere greatly dilated, and present numerous infarctions; the alveolar capillaries are also greatly distented, and their endothelium is swollen. Intra-alveolar spaces packed with lymphoid cells and embryonic connective-tissue cells. The alveoli contain accumulations of epithelioid, highly pigmented cells. These cells are generally found associated with exudative corpuscles in a delicate reticulum. These castiform intra-alveolar accumulations show in places a tendency to become organized.

The pleura is greatly thickened, its vessels dilated and infarcted.

Heart.—Muscular fibers show commencing fatty degenera-

tion, and there is marked amyloid infiltration of the walls of its smaller nutrient vessels.

Liter.—Cell-nuclei alone take carmine staining. Islands of liver-cells found in a translucent, nearly homogeneous basement tissue. Evident amyloid infiltration of the walls of the finer hepatic and biliary ducts.

Kidney.—The Malpighian corpuscles show stiffened capillary loops and little shrinkage from the action of the alcohol. The laminae of the arterioles are pustulous.

Homogeneous, translucent spaces are seen between the smooth muscular fibers of these vessels.

Spleen.—The lymphoid corpuscles of the pulp appeared to me to present an unduly homogeneous, translucent appearance. The smaller vessels show distinct amyloid infiltration of their walls. The Malpighian bodies also show a notable infiltration, having, in some cases, been converted into amorphous masses, which are semi-transparent, and show interspersed among them a few connective-tissue nuclei.

Case of Erysipelas Neoratorem. Presented by Dr. H. M. Fisher.—Was called, March 3d, to see a colored infant, one week old. The child was said to have presented no sign of indisposition until the day previous to my visit, when it suddenly became much agitated, refused to move, and was found to have difficulty in micturition. The tissues of the scrotum and penis were found to be swollen, and in a few hours a faint erysipelatous blush was found pervading their surface.

When first seen, the child was apparently moribund. I could detect no radial pulse, its lips were blue, its extremities cold, and it was in a semi-comatose condition. In the hasty examination I made in the small, badly-lighted attic, in which I found the child, I observed but did not attach due importance to the erysipelatous blush I found extending from the scrotum to the lower part of the abdomen. From the history furnished me, and from the edematous infiltration of the legs, thighs, and eyelids, as well as of the scrotum and penis, I was inclined to look upon the case as one of primary acute nephritis, with secondary erysipelatous involvement of the edematous tissues.

With this view of the case, I ordered that the child should at once be placed in a hot bath, and after the bath applied flannels, wrung out in hot infusion of digitalis, to the patient's loins, and administered a small hypodermic of picrocarpine. Marked temporary improvement followed this treatment; the child emerged for a short time from its semi-comatose condition, cried lustily, and urinated and sweated freely, and marked reduction of the edema was also noticed.

The improvement was, however, of short duration; the child soon relapsed into its former apathetic condition. Death occurred at 11 P.M. The autopsy, made by Dr. McIlvaine, resident surgeon, eighteen hours after death, revealed rigor mortis pretty well established.

Edema of the tissues of the lower extremities, scrotum, and penis was noticed; there was a livid discoloration of the skin of the anterior inner aspects of both thighs, and slight sloughing of the skin of the lower part of the scrotum. The bladder contained about half an ounce of light-yellow, opaque urine. The urine obtained by tapping the bladder, post mortem, showed, on examination, an apparent volume of albumin equal to about one eighth of the column of urine in the test tube. Microscopically, blood- and pus-corpuscles were found in abundance, and a few highly granular tube casts. The kidneys were somewhat congested and lobulated, but their capsule was not adherent, and they did not, at least to the naked eye, present any other evidence of disease. The liver weighed 6 ounces, and was highly congested. The spleen weighed 13 ounces, and was likewise congested, and its surface mottled. The lungs were preyly congealed throughout, but were everywhere crepitant, and floated on water.
The heart weighed two ounces, and presented, on the whole, a healthy appearance, but its posterior mitral cusp appeared somewhat thickened.

The post-mortem appearances leave, I think, but little doubt that the disease was peripheral in its origin, or, in other words, that the erysipelas was the starting-point of it. Probably some comparatively trivial cause, such as a slight abrasion of the skin of the scrotum, suffered, under the very unfavorable sanitary conditions in which the little patient was placed, to light the train of its disease, with all its complications.

The progress of the disease seems in this particular case to have been unusually rapid. If the mother’s statements can be trusted, only thirty-six hours elapsed from its first onset till its fatal termination.

C. B. Nanorede, M. D., Recorder.

MISCELLANY.

The Tri-State Medical Society will meet in English’s Hall, at Indianapolis, on the 18th, 19th, and 20th of September, 1888, commencing at 9 a.m. Excursion rates have been secured on the following railroads: C. C. & I.; Ind’ls., St. Louis & Chicago; Ind’ls. & Wabash; and Ind’ls. & St. Louis; I., R. & W.; Wabash, St. Louis & Pacific; Ind’ls. & Vincennes; J., M. & I.; Pats., Cin. & St. Louis; Vandalia, Evansville & Terre Haute; Ft. Wayne, Cin. & Louisville. The New-Denison, Grand, Bates, and Brunswick Hotels have reduced their rates for the occasion. For further particulars address Thos. B. Harvey, M. D., Indianapolis, Chairman of the Committee of Arrangements.

THERAPEUTICAL NOTES.—Possesses a Bumac of the Fact.—M. Gale- zowski ("Progrès médical," July 21, 1888) recommends the following preparation for those cases of encephalitic or impetiginous eruptions which, in children, often accompany phlyctenular keratitis: B Oil of camphor, 12; 25 centigrammes; red precipitate, 10 centigrammes; vaseline, 10 grammes. M. When numerous crusts are formed it is well to remove them with a suitable forceps, and to cauterize the surfaces thus uncovered with a light application of nitrate of silver, the excess of which is to be neutralized with a solution of salt.

Perchloride of Iron in the Treatment of Typhoid Fever.—M. E. Di- naud ("Union médicale," July 19, 1888) advocates the use of the perchloride of iron, not only in diphtheria, but also in typhoid fever. [In diphtheria he claims for it a special action. See our issue of July 28th.] Although he does not pretend that the iron is a specific in typhoid fever, he believes it to be of great efficacy, not only in adults but in children. No single remedy so tends to relieve the impoverished condition of the blood, the topor of the stomach, and the inflammatory and ulcerative changes of the intestines that characterize the period of decline. Some patients complain that liquid perchloride of iron causes a painful sensation in the pharynx, which they compare to that of a burn. If objection is made to it on this account, the dry perchloride may be given instead. This is now to be had in the form of dragées, a very acceptable preparation for administration. To children a drop of the liquid, well diluted, may be given in broth or in gruel, as often as the latter is taken. The remedy should be begun at the end of the second week and continued until convalescence is complete.

The Formation of Precipitates in Mixtures of Different Tinctures.—M. Pierrelatte ("Gazette hebdomadaire de médecine et de chirurgie," July 18, 1888) calls attention to the precipitates that are sometimes formed in mixing tinctures. Physicians often prescribe mixtures of different tinctures to be taken by drops. Such mixtures are very often turbid, perhaps because the tinctures which compose them are made of alcohol of different strengths; perhaps because there is some chemical incompatibility in the substances mixed together. Sixty-per cent. alcohol, which is nearly half water, dissolves the gummy matters of plants, which are precipitated by stronger alcohol. On the other hand, eighty- or ninety-per cent. alcohol dissolves the resinous matters, which are precipitated by weaker alcohol. In case a precipitate forms in any given case, the liquid can, of course, be filtered, but it is often not known what remains upon the filter. It is well, therefore, in mixing tinctures, to put together such only as are made with alcohol of the same strength. However, even this precaution will not always prevent the formation of precipitates. For instance, if equal quantities of the tinctures of calumba, of gentian, of cinchona, and of the bitter tincture of Banné be mixed together, the resulting compound is turbid. It is found, by combining these tinctures in various ways, that the precipitate results from the reaction of the tincture of calumba and of cinchona with each other. Thus, the precipitate of the tincture of calumba is thrown down by the soluble principles of the cinchona. This precipitation may not destroy the value of the filtered mixture; nevertheless, it is better not to prescribe the two tinctures together.

Preparations of Acouite.—M. Oulmont ("Lyon médical," July 15, 1888) makes the following observations concerning preparations of acouite: The nitrate of acouite will produce toxic effects in doses of a quarter of a milligramme (gr. 1/4). Three milligrammes (gr. 1/2) will kill a good-sized dog. Crystalized acouite will vary in its toxic action according to the origin of the root from which it is made. One milligramme of Swiss acouite will kill a dog in forty-three minutes; the same quantity from Dauphiney in ninety-five minutes; the same quantity from Vosges will not produce death. The alcoholic extract of the fresh stem and leaves is harmless up to twenty grammes. The alcoholic extract of the fresh roots and the tinctures of the dried leaves and of the dried roots are more powerful, but not equally so. Eight to ten drops of the homeopathic mother tincture will kill a dog. The alcoholic extract of the dried roots from Vosges is, next to crystal- lized acouite, the preparation of the most even strength. The proportion of alkaloids depends much on the period of gathering the plants. The alkaloids do not act in the same manner in the preparations obtained from the entire plant. This is true of other active principles, for instance, of digitalin, the action of which is not identical with that of digitalis.

Lobelia Inflata in Thoracic Troubles.—M. Fourrier ("Lyon médical," July 15, 1888) recommends the use of the tincture of lobelia in dyspnea due to mitral lesions and dilatation of the right heart, in pulmonary congestion, and in the third stage of phthisis. In catarhal astima a mixture, each dose of which contains one gramme and a half of tincture of lobelia and half a gramme of iodide of potassium, is said to be useful very often. Lobeline is a simple, non-crystallizable alka- loid.

The Appointment of Externs in the Paris Hospitals.—For the appointments to be made on the 1st of January, 1884, a concours will be held October 9th, at 4 P.M., in the amphitheatre of the Administration building. Students who wish to compete may fill out the secretariat général any day but Sundays and holidays, between eleven and three o’clock, from the 3d to the 27th of September, inclusive.

The Amenities of Medical Journalism.—A correspondent of the "Midland Medical Miscellany" says: "Some medical contemporaries have been inclined to sneer at, or damn, with faint praise, the 'Midland Medical Miscellany.' The amenities of medical literature afford much interest to the book-worm. The criticism on your journal is like the pouring of rose water, when compared with the outpourings of the early numbers of the 'Lancet,' on its rival journals. Here is a speci- mens of its facetious remarks on one of the papers published in 1828: 'A friend of ours,' says the 'Lancet,' "was sitting lately in Callow and Wilson's reading-room, when that facetious wight Joe Burns entered and took up the first weekly occurrence of Macleod's Yellow fungus; he had just raised it to reading distance, when he suddenly removed it from the neighborhood of his olfactory organ with a gesture and ex- plosion of face indicating strong disgust." Joe was asked what he had got [sic] there? 'A bat's—' was the short reply, affording an uncon- cepted confirmation of the naturalist's remark on the bat kind, 'Alii dejectiones in hoc genere futuri horribilibi inhaesit suav.'" This specimen of good taste is outdone by the following: 'Some desirable imit- ations of the 'Lancet' have arisen, trash, and become extinguished;
one or two are still emitting a like foci. If the 'Midland Medical Miscellany' had existed in those days, it would have chided the abuse of epithets so lavishly bestowed upon Earle, Keate, Travers, Sir Ben. Brodie, Dr. Johnson, etc. Fortunately, other times and other masters have come."

A Homoeopathic Cure.—The "Homoeopathic World" reports a case of ulcer of the colon ("pouting" according to the reporter) cured by a single dose of silicea 50 M (T. C.). We are not well versed in this phraseology, but we are given to understand that this was a small dose, being a 30,000th centesimal attenuation."

The Influence of Calomel on Digestion.—Dr. Vassilieff has found, by experiment, that the presence of calomel, at least up to the amount of five grammes, in the alimentary canal does not interfere with the gastric juice, nor affect the triple influence of the pancreatic fluid on albumin, fat, and starch; on mixing the latter fluid with flour and calomel, the formation of certain products, indol, etc., always appearing as a result of prolonged digestion under normal circumstances, is prevented. The gases generated in the process of pancreatic digestion contain none of the usual products of fermentation and decomposition when calomel is present; sulphuretted hydrogen and pure hydrogen are absent, carbinic acid is diminished to from two to ten per cent, while, under natural circumstances, from fourteen to fifty-four per cent, is found in the gases evolved by the action of the pancreatic fluid. In fact, calomel prevents all other changes in nutritive substances, save those produced entirely by the digestive secretions, decomposition and retrogressive processes in albumins being entirely checked. Calomel also prevents butyric-acid fermentation, as Vassilieff found by experiments on cheese. The action of calomel readily explains the cause of the green color of feces passed by patients to whom that drug has been administered. Hoppe-Seyler rightly attributed this coloration to the presence of unaltered bile. Now, under normal conditions, bile and bilverdin are changed, by a process of decomposition, into hydriodolchlorin, and thus become no longer recognizable in the excreta. But this process is arrested by calomel, and the coloring agents, unaltered, give the feces their peculiar bright green hue.

These researches are described at length by Dr. Vassilieff in the "Zeitschrift für physiologische Chemie," vol. vi, page 112. He has found that this action of calomel is due to its power over the microorganisms intimately associated with the process of decomposition which takes place in food during digestion. The drug prevents the development of micro-organisms in the digestive fluids, and also destroys any bacteria and micrococci already developed. This fact was proved first by its acidification. Vassilieff then made a series of experiments to find whether calomel had the same influence in natural digestion. To try grains of calomel were administered to a dog, in two doses, and the animal was killed a few hours later. Under all precautionary conditions, the contents of the intestines were then carefully analyzed. Neither indol nor phenol could be found; and it will not be forgotten by those who study contemporaneous physiological research, that other agents—such as salicylic acid—prevent the formation of indol; and that pancreatic mixtures, formed from natural pancreatic juice, are in fact a pancreatic glandular tissue, undergo septic changes with very great rapidity, in spite of all precautions. None of these changes, nor any formation of indol, occurred in the food taken by dogs to which Vassilieff administered calomel. On the other hand, indol and tyrosin were found in abundance. Under natural circumstances, these products of pancreatic digestion are so rapidly decomposed that they can not be detected in semi-digested food. Hence calomel has no influence on the action of the digestive fluids, but entirely prevents those true retrogressive and putrefactive changes whereby the highly unstable products of these fluids are rapidly decomposed, and micro-organisms quickly developed in great numbers. When calomel enters the alimentary canal, leucin, tyro-in, bilirubin, and other substances remain unaltered, and bacteria are checked and killed.—*British Medical Journal.*

Personal Remembrance as a Test of Parentage.—A case involving the question of legitimacy was tried not long since in Buffalo, and the defendant adjudged to be the father of the child. The points of the case are outlined in the decision of the Appellate Court, which reversed the decision: "Upon the trial the District Attorney asked of the mother of the bastard child, who was then a witness upon the stand, this question: 'Look at the child and tell what the color of its eyes is?' This question was objected to by the defendant upon the ground that it was immaterial, incompetent, and improper. The objection was overruled, and exception taken by the defendant. The witness answered: 'Its eyes are blue.' We are of the opinion that this was an error. This evidence enabled the Court to compare the color of the child's eyes with those of the defendant, who was present in court. We do not regard this kind of evidence as safe or proper. In the case of Petrie vs. Rice (1 Thompson and Cook, 82) the question was as to the color of the child's hair. It was held in that case that such evidence was calculated to, and probably did, prejudice the defendant; that it was improper, and a new trial was granted. The argument used in that case in reference to the color of the hair applies with equal force in this case to the color of the eyes. Common observation reminds us that in families of children different colors of eyes and hair are common, and that it would be dangerous doctrine to permit a child's paternity to be questioned or proved by the comparison of the color of his hair or eyes with that of its alleged parent."

The Appeal to Medical Books in Courts.—The rule as to allowing medical books to be read or quoted from by witnesses on a criminal trial, or even used by lawyers in their arguments, varies in the different States. It was recently stated in a trial in a Western State that medical books could not be used in the courts of Indiana, Maine, Maryland, Massachusetts, Michigan, North Carolina, Rhode Island, Wisconsin, California, and New Hampshire. They can be used, however, in Texas, Alabama, and probably a number of the remaining States. The theory upon which the exclusion seems to be based is that the jury might be drawn away, by the different theories presented in the books, from the proper consideration of the facts relating to the death as given by the witnesses of the deed.

Army Intelligence.—Official List of Changes of Officers serving in the Medical Department of the United States Army from August 11, 1883, to August 18, 1883.—Baxter, Jeremiah H., Chief Medical Purveyor U. S. Army. To proceed to San Francisco, California, via St. Louis, Missouri, on public business connected with the Medical Department; and, on completion thereof, will return to his station. Par. 1. Given 185, A. G. O., August 11, 1883. Baxter, Henry C., Captain and Assistant Surgeon. Replaced from duty at Fort A. Lincoln, Dakota Territory, and assigned to duty at Fort Assiniboine, Montana Territory. Par. 1, S. O. 141, Department of Dakota, August 11, 1883.——Bennett, Richard, Captain and Assistant Surgeon. Granted leave of absence for one month, on surgeon's certificate of disability. Par. 2, S. O. 119, Department of the East, August 18, 1883.——Bennam, R. B., First Lieutenant and Assistant Surgeon. Replaced from duty at Fort Assiniboine, Montana Territory, and assigned to duty at Fort A. Lincoln, Dakota Territory. Par. 2, S. O. 141, Department of Dakota, August 11, 1883.

Naval Intelligence.—Official List of Changes in the Medical Corps of the Navy during the week ending August 18, 1883.—Surgeon George A. Bright, ordered to temporary duty at Naval Residences, Philadelphia, Pa.——Surgeon John L. Nelson, ordered to temporary duty at Fort R. evolving Ship Hancock at Norfolk, Va.——Assistant Surgeon William Martin, ordered to Navy Yard, Pease Island, Fla.

Society Meetings for the Coming Week.—Tuesday, August 28th: Jersey City Pathological Society (private). Wednesday, August 29th: American Dermatological Association—(Skaguen House, Green Island-Lake George—first day); Aurora (N. Y.) City Medical Association. Thursday, August 30th: American Dermatological Association (second day). Friday, August 31st: American Dermatological Association (third day).
Lectures and Addresses.

A CLINICAL LECTURE IN
GYNECOLOGY.
DELIVERED AT THE COLLEGE OF PHYSICIANS AND
SURGEONS.

BY T. GAILLARD THOMAS, M. D.,
PROFESSOR OF CLINICAL GYNECOLOGY.

MALIGNANT DISEASE OF THE CERVIX UTERI.—LACERATION OF THE
CERVIX UTERI PRODUCING STERILITY.

CASE I. MALIGNANT DISEASE OF THE CERVIX UTERI.—

GENTLEMEN: The name of our first patient is Sarah O. She is a native of the United States, fifty-four years of age, and has been married thirty years. She has had three children, but no miscarriages. The menopause took place nine years ago. In answer to our inquiries, she says that she has been an invalid for a year and a half. Eighteen months ago she began to suffer from very severe pelvic pain, which she describes as "twisting" in character, and also to have a discharge, sometimes bloody and sometimes watery, from the vagina, which with the pain has continued more or less constantly up to the present time. She also says that she has lost a considerable amount of flesh, and you can readily see that she has a distended appearance, which might be due either to bodily suffering or mental woe. The only other trouble of which she complains is the occurrence at times of more or less abdominal swelling. The true place to study symptomatology is the clinic, and not the lecture-room. This patient gives her symptoms clearly and graphically, and they are very significant.

We have now gone through what corresponds to the lawyer's direct examination of a witness, and are ready to begin the cross-examination; but in this case the patient has described her trouble so plainly that there is little need of any cross-examination. From her general statement we have already formed an opinion, and that is that the uterus is here the organ at fault; just as we should have suspected the lungs if the pain had been in the chest and the blood had been passed by the mouth. Before going further, I will state an axiom in gynecology which is of great importance, and which you will do well to have firmly fixed in your minds. It is this: If a woman who has normally ceased to menstruate begins to have uterine hemorrhage, always suspect carcinoma. Not infrequently you will see in the medical journals the reports of cases where women who have passed the change of life have begun to menstruate regularly again; but such accounts are altogether deceptive, and, if these cases could be followed out, it would be found, with scarcely a single exception, that the uterine flow was merely the indication of the presence of malignant disease. In other words, there is absolutely no such thing as a return of the menses when a woman has once reached the normal menopause. Not long since a patient of mine in the Woman's Hospital, who is sixty years of age, began to have a flowing from the uterus, and, as there was no indication of any external disease, I applied the curette to the endometrium and drew out some pulpy masses, which I sent to a well-known microscopist for examination. The report that I got from him was that the growth was not malignant in any respect, but was simply a form of polypi. I am perfectly sure, however, that the microscopist is wrong, and for this reason: in the uterus of a woman of sixty, polypi never develop. The organ at that age is completely atrophied. Sometimes in women who have passed the menopause you will find uterine tumors which have all the appearance of fibroids. They are not by any means fibroids, however, but sarcomata. This, then, is a very important point to remember.

From the symptoms in this ease we have good reason to suspect the uterus, and I do not care, therefore, to put any more questions to the patient before making a physical examination, especially since the pain which she has described so graphically is so entirely characteristic of the disease of which I have been speaking. Placing the woman on her back, I find, by conjointed manipulation, that the uterus has undergone the usual atrophy which takes place after the change of life. Upon the cervix, however, there is a hard and resisting mass, of irregular outline, which bleeds freely at the slightest touch. Then, turning the patient upon the side and introducing a Sims's speculum, I find that this mass resembles somewhat a large raspberry in appearance. This can be but one thing, and that is malignant disease. My experience with this affection has led me to make the remark, in my work on diseases of women, that if the physician makes the diagnosis of cancer of the uterus in any case, and attends properly to the diet, cleanliness, and comfort of the patient, in three months time his diagnosis will very probably be strongly disputed by the patient and her friends, on account of the improvement in her general condition, which has resulted from the supporting regimen which he has advised. In the vast majority of instances, however, there is, unfortunately, no mistake in the diagnosis, and the subsequent history of the case proves its correctness. So much for the diagnosis.

Little need be said as to the prognosis. You all know of how little benefit any treatment by medicine is in this affection. The science of medicine has existed since the days of Hippocrates, and all that we can say on this point after these thousands of years is, that there is no drug whatever which any physician but the wildest enthusiast ever gives with the slightest hope of any curative effect. Still, we do give medicines in such cases; but it is more for their moral effect than anything else. With surgery, however, the case is different. Unquestionably, in many instances this can do a great deal for the patient. Only yesterday I met a medical man from whose wife I removed such a growth as is here present, eight years ago, with the effect of arresting the further progress of the disease; and he told me that she was still perfectly well. In order to really benefit such a patient, it is necessary to remove the entire diseased portion of the uterus, however extensive that may be. Nine days since I removed a whole uterus, through the vagina, and the patient did perfectly well until forty-eight hours.
ago, when septicemia set in; and last night she died. I think this unfortunate result occurred, however, because I removed a drainage-tube at the end of twenty-four hours, instead of leaving it in position until all danger of septicemia was past, and I believe that in another similar case it could be avoided. But the removal of the entire uterus, either through the vagina or by abdominal section, I need hardly say is a much more serious operation than ovariotomy.

In cancer of the uterus it is highly desirable, then, to remove all the diseased portion, if possible. In the case now before you, unfortunately, this cannot be successfully accomplished, because the vagina is involved in the disease. We might remove the entire uterus, but it would be of little benefit, as the trouble in the vagina would still remain. The treatment here, therefore, must be merely palliative; and we shall have done all that is in our power for our patient if we try to improve her general condition, and to render her as comfortable and cheerful as possible under the circumstances. I make it a rule never to tell a patient that she has malignant disease, unless there are special and urgent reasons for so doing. Such an announcement is like a death-knell to the unhappy woman, and, by its very depressing effect on her spirits, only hastens the fatal result.

Case II. Laceration of the Cervix Uteri Producing Sterility.—Our next patient is Mrs. Anna P. She is thirty-four years of age, a native of the United States, and has been married twelve years. She has had two children, but no miscarriages, and her last child was born eight years ago. In answer to my inquiries, she says that she has been sick three or four years, that she has complained of pain in the back and side, and of nausea; and that is all, except some burning sensations about the hands and feet occasionally. On further questioning, I find that she is entirely regular in regard to her monthly sickness, but that she suffers a good deal from leucorrhoea, and that there is considerable irritation about the bladder, which oblige her to get up at least three or four times every night to pass her urine.

Before telling you what the physical examination revealed, I will merely mention that this is a totally different kind of a case from the last, in the fact that the condition present is an entirely remediable one. The patient lying upon the back, and my finger having been passed up into the vagina, I found that the cervix was of twice the normal size, and that the body of the uterus was also considerably enlarged, but not nearly to the same extent proportionally as the cervix. Furthermore, the cervix was found to be very much spread out, and its surface felt as if it were covered with a large number of millet-seeds. If one of these little protuberances was scraped with the finger-nail, a viscous liquid would issue from it which felt very much like white of egg to the touch. Finally, it was found that one lip of the cervix was pressing directly upon the bladder. The patient's position was now changed to the side, and a Sims's speculum introduced, after which the uterine probe was passed to the normal extent. Through the speculum it could readily be seen, however, that there was well-marked laceration of the cervix, and, when a tenaculum was put into each lip, the torn surfaces could be brought into complete apposition. This laceration was absolutely the only abnormal condition present, as far as could be made out; and we have here, therefore, one of those simple cases which the gynecologist loves to meet with, and which usually yield the most admirable results.

Next let us inquire, Does this condition of laceration of the cervix account for the symptoms which are presented in the case? for if it is not really the cause of the symptoms of which the patient complains, our diagnosis is certainly wrong, and there must be some other pathological condition present which gives rise to them. The symptoms are, in brief, backache, pain in one side, dysuria, leucorrhoea, and nausea; and there is one additional one that should be mentioned, viz.: sterility, since she has not been pregnant now for eight years. It is impossible to say in which of her two confinements this woman's cervix was lacerated, as, from her account, neither of them seems to have been at all complicated; but it is probable that it occurred in the second. When the cervix uteri is in the condition that this one now is, it is almost invariably in a neurailge state, and the pain is reflected through the uterine ligaments to the lower part of the spine, which accounts satisfactorily for the backache. In the examination, the left ovary was found to be tender on pressure, and this is to be explained also by the condition of the cervix, which keeps up a more or less constant oophoralgia. The cause of the leucorrhoea is too evident to need any comment; while, as we have seen, one of the lips of the lacerated cervix is pressing directly upon the bladder, which sufficiently accounts for the dysuria. All of the symptoms, including the sterility, are satisfactorily explained, therefore, by the diagnosis that has been made, and there certainly can be very little doubt that it is the correct one in this ease.

Now as to the treatment. There is but one thing that can do any good in this ease, and that is an operation for the restoration of the lacerated cervix to its normal condition. If the woman will consent to enter my service at the Woman's Hospital, she will be placed on preliminary treatment for ten days or a fortnight, and then the operation will be performed, this preliminary treatment consisting principally in the application of the hot douche and the careful regulation of the bowels. The operation for lacerated cervix—which, as you know, consists simply in paring the lips and keeping the denuded surfaces in apposition, by means of silver-wire sutures, until union has taken place—should always be done at least two weeks before the time for the menstrual period. Gynecologists in this country, at least, are fully satisfied as to the immense benefit often to be derived from this operation. In Europe there is at present manifested an extraordinary amount of opposition to it; but I am thoroughly convinced that, when its advantages come to be properly appreciated, it will be as completely established there as it is here. In the present instance, I doubt not, the operation will remove all the symptoms, including the sterility, and our patient will not only get well, but get well rapidly.

In conclusion, I wish to reply to a question which has just been sent me by one of the members of the class, viz.: Is there danger of cancer being propagated by means of
sexual intercourse? There is, undoubtedly, great danger of this occurring, and repeated instances of cancer of the penis being contracted in this way are on record. The slightest abrasion of the penis may be sufficient for the absorption of virus from the malignant growth, and the husbands of women suffering from cancer of the uterus should, therefore, always be warned against intercourse with their wives. This, as you see, is a matter of very considerable importance, and I am glad that the point has been suggested.

ACNE:
ITS ETIOLOGY, DIAGNOSIS, AND TREATMENT.
BY GEORGE THOMAS JACKSON, M.D.,
NEW YORK.

Acne is an inflammatory disease of the sebaceous glands and the hair follicles of the skin, manifesting itself by an eruption of variously sized papules, pustules, or tubercles, generally confined to the regions of the face and shoulders, appearing usually about the age of puberty, and tending to run a chronic course.

Etiology.—As in other diseases, so in acne, we have predisposing and exciting causes. The great predisposing cause is found in the quality of the skin, its aptitude in certain individuals for developing that form of glandular inflammation with which we are now concerned. This quality of skin is most evidently present in persons of the lymphatic or stramous diathesis. Such individuals have pale, thick, muggy, more or less oily looking skins, with plainly visible pores. In many cases of acne the predisposing cause is not so clearly indicated, nor is there evidence of any diathesis; but it is necessary to assume in all cases some predisposition on the part of the skin, since we know that the same factors which in some people will act as exciting causes, in others will fail to give rise to the disease.

By some authors it is said that blondes are more prone to acne than brunettes, but the difference, if any, is small. How far hereditary tendency may be a predisposing cause is hard to decide, since the disease is so common that it would be easy to find a history of acne in some of the ancestors of almost every patient.

Exciting Causes.—The first great exciting cause is puberty. Then is the period of great developmental activity, the whole body undergoing marked change, nowhere more plainly seen than in the growth of the sebaceous glands and hair follicles. This physiological activity may act as an excitant to an outbreak of acne by becoming pathological, growth taking place too rapidly for the nutritive capabilities of the individual, and anemia being caused. Then the nutrition and innervation of the sebaceous glands are interfered with, they receive a poorer quality of blood than they should, and their epithelia do not undergo the normal fatty change into sebaceous matter as in health. These products of incomplete metamorphosis accumulate in the glands and their ducts, act as foreign bodies, and cause inflammation and acne pustules. Again, the rapid development of the hair and glands is attended by an increased flow of blood through the capillaries of the skin. At puberty, reflex nervous influences act easily upon the capillaries of the skin, and blushing is readily induced. The activity of the sebaceous glands is over-stimulated by the more or less constant hyperemia, and, as a consequence, the sebaceous matter is formed too rapidly, is not cast off, but accumulates in the glands, and, becoming inspissated, acts as a foreign body and causes inflammation and acne.

Dyspepsia is a frequent exciting cause of acne. Gubler ("Lyon méd.," 1870, v, 341) believes that the chief relation between digestion and acne is a non-assimilation of fat on the part of the intestines and stomach; and Weisse ("Arch. of Dermat.," New York, January, 1876, p. 107) affirms in support of this view that fat people and beer drinkers are not so frequently affected with acne as others. Constipation is another frequent exciting cause.

Uterine and ovarian disorders of all grades, whether functional or organic, are frequent excitants and aggravants of acne. Many women with usually smooth skin are annoyed by the appearance of one or more pimples at each menstrual period. Many women have acne during pregnancy, and at no other time. The cases arising from disorders of the sexual organs in the female are among the most obstinate with which we have to do, and often our therapeutic art is powerless. Acne of the chin has been erroneously supposed to have uterine disease for its peculiar cause.

As to sexual excesses or over-continence as causes of acne, Niemeyer ("Text-Book of Pract. Med.," New York, 1876) says: "The laity go further, and, according as they are inclined to regard mankind from a gloomy or a favorable point of view, they ascribe acne to masturbation or sexual excess, or else attribute it to excessive chastity or over-continence." That excessive masturbation and venery may be exciting causes of acne in young people is quite likely, acting through their damaging effect upon the constitution and morale of the patient. That chastity should have such effect is extremely unlikely. Jonathan Hutchinson ("Med. Times and Gaz.," London, 1877, i, 17) believes that acne is due more to sexual irritability than to exhaustion, and more errors of innervation than of circulation.

Denslow ("N. Y. Med. Jour.," xxxiii, 1881, p. 189) believes that inertia or inadequacy of the non-striated muscles of the skin (rectores pilorum), one of whose offices is to empty the sebaceous glands, either alone or in connection with over-secretion of sebum and accumulation of the same in the glands, is an important factor in aetiology. He says that the muscles become inadequate when the glands are in a state of unusual activity, as at puberty or under local irritation, as heat, cold, etc.; and when some physiological or other constitutional disturbance causes interference with their innervation or blood supply, as at puberty, and with menstrual and intestinal disturbances.

General plethora may aggravate a pre-existing acne as well as a too hearty meal. That anemia and chlorosis
should be exciting causes may be surmised from what was
said under puberty as a cause.

Then there are certain drugs whose external or internal
use will produce acne. Such are tar, bromine, and iodine.
Tar, locally applied for its therapeutic effect, or coming in
contact with the skin in its manufacture, will stop up the
ducts of the glands and cause inflammation and acne.
Sometimes it seems to produce acne by its systemic effect,
the pustules appearing where the tar was not applied.
Bromine and iodine, when taken into the system, are par-
tially excreted by the sebaceous glands, and by their pre-
sence during the process of excretion act as irritants to the
glands and cause acne pustules.

Comedones, plugging up follicles by extraneous matter,
want of cleanliness, use of cosmetics, exposure to extremes
of heat and cold, the rubbing of a greasy hat-band upon
the forehead, or the related wearing of "bangs" on the
part of the young women, are a few more causes of acne
given by different writers, sufficient, no doubt, in some
cases, to excite or aggravate the disease. Ohmann-Dumes-
has recently brought forward the claims of renal disease to
be considered as an aetiological factor.

As to the forms of acne, the more severe are apt to
occur later in life than the milder, and to be more evidently
related to disorders of the internal organs. Most cases
begin between the ages of fifteen and twenty years, and
tend to subside and disappear between the ages of twenty-
five and thirty years.

Schwimmer ("Die neuropathischen Dermatosen."
Wien u. Leipzig, 1883) places acne under the head of "su-
perficial inflammations partly of tropho-neurotic nature."

Diagnosis.—We will first consider the characters of the
different forms of acne, and then pass to the differential
diagnosis between it and other diseases with which it may
be confounded.

Acne vulgaris is composed of three sub-varieties. 1.
More or less acuminated elevations of the skin located about
the mouths of the sebaceous ducts and hair follicles, pin-
head sized, and of whitish or reddish color, forming acne
papulosa. 2. Papules as just described, but with a minute
blackish speck on their summit, indicating the mouth of
the gland duct, constituting acne punctata. 3. The papule
is surmounted with a yellowish-white pustular head, or has
undergone degenerative changes into a pustule. The pustu-
les are pin-head to split-pea size, are surrounded by a zone
of inflammation, with some degree of induration at their
base. This is acne pustulosa. Usually papules, papulo-pus-
tules, pustules, comedones, and scars from old lesions form
the typical acne vulgaris as it presents itself to the physician.

Acne indurata differs from acne vulgaris chiefly in the size
of its lesions, and may be considered as an exaggeration of
acne pustulosa. Its lesions are split-pea size and over, dark-
red or violaceous in color, sometimes project quite promi-
nently over the niveus, and sometimes may be felt as hard
lumps under the skin. Suppuration goes on actively in
them, and they not infrequently take on the form of dermic
abscesses.

Acne atrophica and acne hypertrophica are really the
last stages or results of the other forms. In acne atrophica
an atrophy takes place about the ducts of the glands, leav-
ing minute pit-like cicatrices. This form is allied to the
acne frontalis of the Germans, which is described as occurr-
ing mostly on the forehead, near the hair, in the form of
tubercles or pustules, surmounted by a crust, which always
heal with the production of circumscribed deep cicatrices.
In acne hypertrophica there is a hypertrophy of the con-
nective tissue about the glands, and the projection above
the level of the skin of a persistent indurated papule or
pustule.

Acne artificialis seu medicamentosa, caused by drugs
either locally applied or acting from within, has three prin-
cipal varieties, named from their different causes: viz., tar
acne, bromine acne, and iodine acne. This form of acne is
apt to be more scattered over the body, and to appear in
places where acne vulgaris is not seen. Tar acne exhibits
a number of black points (the plugged-up follicles), together
with inflamed papules and pustules, with more or less hyper-
amia of the skin between. These lesions are located upon
the exposed skin of those people who work with tar, or
anywhere upon the body where tar has been therapeutically
applied, as on the arms, thighs, etc. Bromine acne is com-
poved of discrete inflamed papules, or the papules may be
closely pressed together, forming infiltrated patches, and
not infrequently there is ulceration. It is sometimes pre-
ceded by febrile symptoms. Though most frequently upon
the face, chin, and other parts of the body, it is a more general
eruption than acne vulgaris, and is often found in the axilla, on
the thighs, and on the arms. Its lesions disappear, leaving sometimes
brown pigmentation and often cicatrices. Iodine acne is
more acute than acne vulgaris; its lesions are of more equal
size and have more intensely red bases, and the eruption is
usually accompanied by other symptoms of iodism. It is
more prone to appear on the face, neck, shoulders, chest, and
arms. The diagnosis of these forms of acne medicamen-
tosa is further rendered easy by the history of a use of the
different drugs.

Differential Diagnosis between Acne and Rosacea.—Ros-
acea is due to dilatation of the blood-vessels, hyperemia,
and subsequent development of connective tissue, the seb-
aceous glands being affected secondarily. Acne is primarily
a disease of the sebaceous glands. Rosacea occurs usually
in people over thirty years of age. Acne is a disease of youth,
beginning between the ages of fifteen and twenty. In rosacea
we usually have a history of some uterine, digestive, or other
organic disorder, or by exposure to cold, drinking of spirits,
etc. In acne in many cases no apparent cause can be dis-
covered. In rosacea the eruption takes the form of more
or less circumscribed reddish or bluish-red patches, with en-
larged and prominent blood-vessels running through them,
sometimes associated with acne pustules. In acne the eru-
pation consists of more or less discrete inflamed papules and
pustules, intermixed with comedones. Rosacea is usually
confined to the nose and chin. Acne is scattered over the
face and shoulders.

Impetigo is met with very frequently in young children.
Acne is excessively rare before puberty. Impetigo is an
acute disease preceded by constitutional symptoms. Acne
is a chronic disease without constitutional disturbances. The eruption of impetigo consists of superficial, rounded or comedones, and prominently raised above the surface of the skin. Acne is usually accompanied by papules and comedones, and if large they become dermic abscesses, as in acne indurata. Impetigo either dries into a yellow scab, or, being ruptured, forms a thick brownish or yellowish crust. On healing, it leaves no pigmentation or scar. Acne does not form yellow crusts, and often leaves scars.

Syphosis is a disease of the hair follicles. Acne is principally a disease of the sebaceous glands. The eruption of syphosis consists of papules and comedones appearing on the hairy parts of the face and neck, more rarely on the scalp. Acne occurs on the non-hairy as well as the hairy parts of the face and neck, and does not occur on the scalp. Each papule of syphosis is pierced by a hair, and the disease causes much crusting and sometimes loss of hair. In acne the papules are not pierced by hair, nor do they give rise to alopecia, and there is not much if any crusting.

Variola is an acute disease, accompanied by constitutional symptoms, appearing on the general surface of the body, and consisting of uniform papules which go through a regular course of development, becoming umbilicated, and ultimately breaking down with the formation of thick crusts. The whole course of acne is different. In any doubtful case, a few hours will decide the diagnosis from the course of the lesions.

**Papular Eczema.**

**Acne vulgaris.**

1. Begins usually about the age of puberty.
2. A chronic disease confined usually to face, neck, and shoulders.
3. Consists of papules, pustules, and comedones, sometimes with much infiltration about the sebaceous glands.
4. Little tendency to grouping of lesions.
5. As a rule, does not itch, and no scratch marks.
6. Sometimes leaves cicatrices on healing.

**Acne indurata.**

1. Appears shortly after puberty.
2. Special predilection for the face and shoulders; not usually found elsewhere.
3. Usually accompanied by acne vulgaris and comedones.
4. Discrete, large, dark-red or violaceous indurated tubercles which of themselves show little tendency to rupture, and less to ulcerate. Rather soft to the touch, and contain pus.
5. No tendency to grouping.
6. On healing, leave small pith-like cicatrices, or else no trace.

**Acne pustular Syphilide.**

1. Begins somewhat later, though it may appear at any age. Preceded or accompanied by other lesions of syphilis. Generally distinct evidence of venereal infection, and there may be systemic disturbance at the time of appearance of eruption.
2. A general eruption, often invading the scalp.
3. A greater uniformity in the character of the lesions. The papules form on the top of papules.

**Tubercular Syphilide.**

1. Appears somewhat later. May come at any period of life and with other symptoms of syphilis.
2. May come on any part of the body. Frequently on the forehead alone, at the roots of the hair.
3. Usually the only lesion, and very uniform in development. If early, it will be symmetrical; if late, non-symmetrical.
4. Dark-red or ham-colored tubercles surrounded by a well-marked areola, firm to the touch; often have a smooth, glistening surface, and do not contain pus. Often ulcerate.
5. Tend to group into more or less irregular patches, sometimes forming segments of circles, kidney shapes, etc.
6. If they have lasted long, they tend to leave pigmented and punch-out cicatrices with well-marked areola. Pigmentation and areola slowly disappear, and white scar remains.

**Treatment.**—In the treatment of acne we use internal, or constitutional, and external, or local, remedies.

In the constitutional treatment of acne we strive to follow the same indications as in general medicine, endeavoring to restore the body to proper tone. To anemic patients we administer tonics—as iron, quinine, cod-liver oil, etc. Strumous patients improve under iodine, with cod-liver oil or other tonics. The sirup of the iodide of iron, and the iodide of starch, are specially suitable. To the plethoric, depletives should be administered. In cases where there seems to be sluggishness in the processes of waste and repair, acetate of potassium, in fifteen-grain doses, given three times a day between meals, and in a wineglass or more of water, does good.

For constipation, give such directions as to regulation of food, etc., and use such remedies as you would use in other cases. When we have to treat a patient with furred tongue, dyspepsia, and tendency toward constipation, the following combination will prove useful, viz.:

- Magnes. sulph., ⅔ iss.
- Ferris sulph. exsicc., gr. xvi.
- Acr. sulph. dil., 3 ij.
- Aquæ, ⅔ viij.

**M. Sig.** ⅔ ss. in a goblet of water once or twice a day.

If dyspepsia is marked, the dilute mineral acids, tinutere of nux vomica, and the bitter infusions, will be useful. Of late I have had good results from a plan of treatment advocated by Leube (Volkmann’s “Sammlung klinische Vorträge,” No. 62), and would commend it to the profession for further trial. His plan is to give dilute hydrochloric acid, in six-drop doses, one hour after each meal, and then again three hours after that, so that six doses of the acid are taken each day. The diet must be regulated. Uterine disorders must be treated when present, and their
cure will often be attended by the cure of the acne. We often see in our female patients with acne that, after marrying and giving birth to a child, the eruption, which before seemed to laugh at our endeavors to cure it, will completely disappear, fading away of itself.

General hygienic principles should be inculcated in all cases. Plenty of exercise in the open air is essential. In some cases, having the patient get thoroughly sunburnt by exposure to the sun and wind for a few days will greatly improve the face. Cold sponge baths in the morning are to be recommended. Russian, Turkish, and sulphur baths are good, and their effect is nowhere more brilliant than in acne of the back and shoulders.

Arsenic, calcium sulphide, glycerin, and ergot deserve special mention as drugs addressed to the nutrition of the skin. Arsenic is of benefit in the more chronic form of acne, where there is not much activity of pus production. The dose to begin with should be three to five drops, Fowler’s solution being the preparation used, gradually increased to twenty drops, three times a day, watching the effect carefully, so as to avoid poisoning. Calcium sulphide (caixa sulphurnata) is highly spoken of by Ringer, Piffard, and others. Piffard ("Journ. of Cutan. and Ven. Dis.", New York, January, 1883) says that the dose of the drug must be proportioned to the state of the skin and the effect produced. In some cases gr. $\frac{1}{10}$, once or twice a day, will cure, while in others a full grain, repeated with sufficient frequency to provoke the physiological action, will be necessary. Further, he says: "In cases of acne simplex, with acute purulent lesions, the smaller dose is most appropriate, and should not be too long continued, while in sluggish papules, occurring in lymphatic subjects, $\frac{1}{10}$, or even $\frac{1}{2}$ a grain should be given, with frequent repetitions, and until pustulation is imminent. When this point is reached, the drug should be discontinued. At this juncture amendment usually commences. This may continue for some days, and until the effect of the drug wears off. A renewal of the medicine again brings on a semblance of acuteness, and, when this subsides, improvement is further manifested." Thus he administers and leaves off the drug till the cure is complete. The use of glycerin was first advocated by Guller, upon the theory that acne was due to a malassimilation of fat, and he administered the drug in the hope that it would, by increasing the amount of fat in the blood, prevent the insipidness of the sebaceous matter in the glands. He gives it in doses aggregating one half ounce a day. This plan is also followed by Weisse ("Arch. of Dermat.", New York, January, 1870), who administers the glycerin with tincture of gentian, and orders plenty of fatty food and malt liquors in the dietary. Ergotin, according to Schwimmer, of Buda-Pesth, was first introduced to the profession as a remedy for acne by Rossi and Lombroso, of Italy. Denslow, of this city ("N. Y. Med. Jour.", xxxiii, 1881, p. 189), also recommends the fluid extract of ergot, in 3 ss. doses, to act upon the unstripped muscular fibers of the skin and overcome their inertia. Hardaway, Heitzmann, Hyde, and others have spoken well of this plan.

Local measures are of as much importance in the treatment of acne as general therapeutics, if not more. It is the aim of this article to mention only a few plans of local treatment which promise the best success.

Surgical measures, if not absolutely essential, will hasten on a cure. The instruments of use in acne are: 1. A sharp-pointed, straight bistoury; or, better, an acne-knife consisting of a short, broad, double-edged, triangular blade, with a prominent projecting shoulder about an eighth of an inch from the point. 2. A comedo-presser, which may be Piffard’s, like a modified fenestrated watch-key; or Fox’s, a straight silver tube, the one I prefer; or else an ordinary watch-key. 3. The dermal curette. Every pusule is to be freely incised with the bistoury and its contents pressed out by the thumb-nails. In patients who will allow it, and especially in cases which have lasted a long time, the dermal curette is one of the best and speediest means of getting rid of the pusules. Behrend ("Deutsch. med. Wochen-schr.," xx, 1881, p. 283) recommends its use every second day at first, and then every third day, being careful at every sitting to scrape away all the crusts left from the previous sitting. The curette will only attack the unsound skin, and will do no harm to the healthy skin, nor leave any unsightly scar. If only a few isolated papules are to be destroyed, the smaller-sized curette should be selected. But, if a large surface is to be gone over, choose a large-sized curette. This should be held firmly in the hand and passed rapidly over the papules and pusules, the bleeding being encouraged by the application of hot water. Patients fearing disfigurement from the use of the bistoury or curette should be assured that either there will be no scars left, or there will be far less scarring than if the pusules were left to themselves.

All comedones should have their central core pressed out by means of one of the comedo-pressers spoken of above. Usually firm pressure made perpendicularly over the comedo will be quickly answered by the expression of the plug. If they prove obstinate, they will yield more readily after steaming the face for a few minutes, or washing it in hot water.

In very inflamed acne, soothing measures may be called for, either lotions, such as the "lotio calaminæ et glycercinæ" of Bultky’s "Manual of Skin Diseases," viz.

- $R$. Pulv. calaminæ preparæ, 3 ss–j.
- Ziniæ oxid., 3 j–iij.
- Glycerinæ, 3 j–iij.
- Aq. roseæ, $\frac{3}{4}$ iv.

or ointments, such as the ungt. zinci oxid., or ungt. roseæ.

But usually more stimulating measures are needed. In a majority of the lotions for acne, sulphur in some of its forms plays the leading part, and in varying strength, from 3 ss. up to 5 ss to the ounce of excipient. Mercury is also used, as the bichloride, gr. $\frac{1}{4}$–ij to the ounce. In very sluggish cases and in acne indurata good results may be expected from mercurial ointments, and of these a very good one is:

- Hydrarg. chlor. mitis, 5 j–iv.
- Petrolæi, $\frac{3}{4}$ j.

M.
Sulphur ointment may also be used, though its effect must be watched. The treatment by green soap frictions is an excellent one. The simplest mode of using the soap is to order equal parts of saponaria viridis and alcohol, and to have this well rubbed in on a piece of flannel once or twice a day, and then washed off with warm water. If the disease is very indolent, the soap can be left on all night and washed off in the morning. After a few days this treatment will cause a great deal of irritation, and the skin will peel off. Now stop the frictions and apply ung. zinci oxid., or any simple ointment. Usually when the skin resumes its normal color the acme will be less marked. If necessary, repeat.

Living ("Lancet," 1878, i, p. 58) recommends that the soap frictions be followed by a sulphur lotion, such as:

B. Sulphur preeip., 3 j.
Glycerine, 3 ij.
Alcohol, 3 j.
Aq. rosea.
Aq. calcis, ââ 3 iij.

This is to be left on all night. If it is not well borne, he substitutes for it the following:

B. Calamine.
Bismuth. subnitrat., ââ 3 ij.
Alcohol, 3 ss.
Glycerina, 3 j.
Hydrarg. chlo. mit., gr. iij.
Aq. rosea, 3 viij.

Sand frictions have been recommended, but they are not so elegant or efficacious as the soap treatment or the curette. Some dermatologists recommend touching the pustules, after opening them, with some strong acid on a glass rod. McDonnell ("Canada Med. and Surg. Jour.," March, 1880, p. 351) reports a case of acme indurata cured by cryophanetic acid, gr. xv– 3 j. It is to be remembered that cryophanetic acid is very irritating to the face at times.

If a case is recent, and quite inflammatory, it is well to open all pustules and direct the patient to bathe the face in hot water, or hot water with borax (3 ij–Oj), before going to bed, by sopping the water on for five or ten minutes, and then to apply the soothing application chosen. In the morning wash off the lotion with cold water and apply some starch powder. These ablutions with hot water are to be used before the application of any lotion or ointment.

Many cases will be very obstinate and resist our best efforts. Most cases require weeks or months for a cure. If marriage is proposed, we can give our sanction, and assure the patient that, after regular sexual intercourse in moderation is established, the acme will be likely to disappear. In women child-bearing will often prove more curative than any other agent. But no physician is justified in advising illicit sexual intercourse to a man any more than to an innocent girl, and the latter he would hardly dare to do. Such advice would be derogatory to the high moral tone which a physician of all men should maintain, and most probably would fail of doing any good to the disease. At any rate, the danger involved is far too serious to be assumed for so trivial an affair as acne.

THE PATHOLOGY OF ACUTE LOBAR PNEUMONIA

FROM A NEW STANDPOINT.

By WILLIAM D. SCHUYLER, M. D.

(Continued from page 209.)

Professor Flint's statements are most affirmative. He says: "From the relatively excessive amount of the exudation, its derivation from the branches of the pulmonary artery, its complete removal by absorption and expectoration, an extension of the local affection to a second or third lobe, and the laws of the disease as regards the greater liability of the lower lobes, and of the lower lobe of the right lung—these are points" (he says), "which, to say the least, are suggestive of dependence upon a constitutional morbid condition, the latter being essentially the disease." "It is not easy to reconcile the pathological facts just stated with the doctrine that the pneumonic products are the result solely of a local inflammatory condition; and, if a prior constitutional condition be essential, that condition is a fever." In support of which deduction he further says: "The local affection is never produced by local causes; and all the knowledge which we at present have of the causation is in favor of the primary action of the cause being constitutional." Also: "The disease, as well known, is not infrequently an intercurrent affection in the course of the essential fevers—namely, typhus and typhoid fevers, measles, and diphtheria. In these instances the determining cause is constitutional." Having thus established the constitutional origin of the malady, this author goes on to say: "Etiological proof of a specific causation is afforded, first, by the prevalence of the disease at certain seasons of the year—namely, in the vernal months in this climate; second, by the fact that it is far more prevalent in some climates than in others, to wit, in the Southern than the Northern States in this country." "To these facts is to be added, that at different periods and places the variations of the disease as regards its phenomena and fatality, while they constitute a point of distinction from the purely inflammatory affections affiliate it with the essential fevers." The clinical history, character of the chill, the sudden rise of temperature, often out of proportion to the local disease, time of defervescence while resolution is not yet complete, or has merely begun— which sometimes begins and ends within twelve hours, showing self-limitation as in typhoid fever, which ends when the disease has finished its career—and the frequent presence of typhoid symptoms also, ally it to the fevers (Flint). There is no tendency to relapse when the disease is ended, and it does not persist in a chronic form, points in which it also resembles the essential fevers (Flint). Our author holds that "these characteristic clinical facts are undoubtedly due to the fever, irrespective of the pulmonary affection."

Moreover, the constitutional character of its genesis,
just shown by Flint, and as emphatically claimed by Jurgenssen; the comparative rarity of discoverable causes for its production (W. Fox); our inability to produce the disease experimentally (Flint, Jurgenssen); the cyclical course of the process, including the sudden febrile rise, and the character and extent of defervescence; absence of uniform relations between the extent of the local lesion and the general symptoms, the self-limitation of the pyrexia and its termination by crisis; these facts it is claimed further, or also, ally acute pneumonia with the essential fevers.

Thus I have endeavored to give a statement of the entire ground upon which the pyrexial hypothesis rests, and summing up the points presented we find the basis for affirming acute lobar pneumonia to be essentially a fever as follows: It is shown that the pneumonic phenomena can not be the result of an inflammatory state, or of a simple inflammation of the lungs; that, therefore, it must be a constitutional disease, and hence essentially a fever (Flint, Jurgenssen). Because it occurs most at certain seasons of the year, and is more prevalent in some climates, it is held to be specific (Flint). Its febrile character is further claimed to be established by the phenomena of its course (Flint, Jurgenssen), and it is thought not improbable that occasional prodromal symptoms strengthen this claim.

That this malady is not an inflammatory disease I have already been at some length to show; that it is of constitutional origin or genesis, which view is generally held, or is fast gaining ground, and is indicated by all the knowledge we have of its causation in general, I believe, although, as I shall point out, strictly local conditions may cause its initiation; but that it is a fever because it is not an inflammatory disease, and because it is of constitutional origin, and, furthermore, that such fever is specific because in many of its phenomena and in its course it somewhat resembles the essential fevers, I hold is not yet proved. It will be observed that the deduction that it is a fever, essentially, so far has been made on the ground of exclusion—to wit, that, if a constitutional condition be essential, that condition is a fever (Flint); which can not be accepted as scientific or final unless it shall or can be shown that upon 'this basis, and on no other possible hypothesis, can all the phenomena of the disease be explained.

And the further facts that it is an intercurrent affection in the course of the essential fevers, that the disease prevails most at certain seasons in the year—in the winter and spring months—that it is more prevalent in some climates than others, and that it varies greatly in different seasons in its fatality, do not strengthen the foregoing deduction; because these results may also be accounted for on other grounds.

Furthermore, the same criticism may be applied to the facts of its clinical history, which, though it comprises a pronounced chill, sudden temperature rise—often out of proportion to the local affection—termination by crisis, a marked defervescence and a cyclical course, and while these phenomena may liken it to the essential fevers, yet they do this only in a general way. In no particular, as we shall see, is the likeness special, and the phenomena may otherwise be accounted for.

But there are other points against the febrile hypothesis which may be advanced: First. "Although this disease is not infrequently an intercurrent affection in the course of the essential fevers, yet, as it is only an occasional complication, the determining cause involves something which does not pertain to these fevers" (Flint). Something, a special or specific cause, is here rendered necessary, and this, we are told, "it is reasonable to conclude is pneumatic fever." This specific cause, however, "the essential causation," it is conceded, "is not demonstrable" (Flint); which, with the farther fact that many hold a single blood-poison inadequate to account for the development of the disease under all circumstances, as it appears in every country and latitude of the globe, in individuals of every age and condition of life, and, I may add, as it is developed in animals—notably in the horse—renders the existence of a special cause more than doubtful.

Second. While in some respects the pathology of acute lobar pneumonia resembles that of the essential fevers, especially in being comprised of characteristic constitutional phenomena and an equally pronounced characteristic local lesion, also in being self-limited, in manifesting a cyclical course, and in the absence of a close general relation between the degree of the constitutional symptoms and the extent of the local lesion, yet these points of similarity are general, and not sufficiently special to warrant their being used as a basis of deduction. On the other hand, in the matter of etiology, of exact comparison of symptoms and course of morbid anatomy, and of dangers and treatment, it is most unlike those diseases. Etiologically, it does not occur at the same seasons of the year that typhoid fever— to which it has been compared as allied—prevails; nor is it limited with it in the area of its development; it is not propagated by contagion, while typhoid is; and it does not occur—the form we are studying—in epidemics. As stated, pneumonia is most common in the winter and spring months, while typhoid is most common in the autumn, or may occur throughout the year. Pneumonia of the acute lobar form is eminently sporadic, and does not propagate itself. Furthermore, while the fevers mentioned are somewhat protective against a second attack, pneumonia, on the contrary, rather predisposes to a second attack than otherwise.

In symptoms and course the diseases are unlike. It is hardly necessary to do more than to allude to the sharp chill and rapid development of the one—pneumonia, and the prolonged, uncertain chill and gradual, daily progressing development of the other—typhoid; of the termination by crisis of the former, and the extended resolution of the latter. The symptoms and causes also of typhus and the disease we are considering are equally dissimilar. Pathologically:

The local process in pneumonia has more than once been likened to the intestinal lesion of the solitary and agminated glands in typhoid fever. Just how the anatomical changes which occur in the lung in pneumonia coincide with the lesion of typhoid I am unable to determine. They are not similar in any particular; on the contrary, they are most dissimilar in their development, course, and results. The development of the pneumatic process is most rapid, the time required for its completion in some cases being only
a few hours; while the intestinal lesion of typhoid forms slowly and requires days for its completion. The course of the former is singularly rapid, its completion and removal being quickly accomplished without causing injury to the structure implicated; while that of the latter is slow, and generally destructive of the organs involved. Again, the results of the two processes are unlike histologically; the exudation of pneumonia being made up of preformed elements—namely, of an increase of brouchnal mucus, the liquor sanguinis, white or colored blood-corpuscles, red blood-corpuscles, and some increase of detached epithelium; while the exudation in the intestinal glands is a new formation, consisting of a proliferation of nuclei and a low grade of epithelial elements, which, with the softened gland structure, make up the so-called medullary infiltrate. The two processes further differ in color, the pneumonia being at first a bluish-red, afterward yellowish-gray, while the typhoid lesion from the first, or very early, presents the shaven beard, pinkish-gray appearance. Further, in regard to the clinical unlikeness, except that in some cases the asthenia of pneumonia resembles the debility of typhoid, the symptoms are most dissimilar. The thermal curves of the two maladies, considered as essential fevers, which should exhibit any inherent likeness, are most unlike; that of pneumonia being acute both in its ascent and decline, while the curve of typhoid is, in the main, gradual and most regular in its ascent (this being interrupted only by regular daily remissions and exacerbations), and most irregular and uncertain in its decline. The indications for the treatment of the two diseases, as we shall find, are not less diverse; while in the main those of the typhoid disease are mildly antiphlogistic, sedative, alterative, and for support, in pneumonia at first they are eminently expectant and symptomatic, as derived from the constantly changing physical or physiological conditions; afterward, they are wholly tonic. As we shall find, no alternative indication, which is the sheet-anchor of treatment in typhoid, is met with in pneumonia. Further, I would only remark that the difference exhibited by the morbid anatomy alone should justify a distinct classification for the two diseases.

On account of its cyclical course, Juergensen likens croupous pneumonia to the intermitents, the acute exanthemata, acute rheumatism, and epidemic cerebro-spinal meningitis. It is unlike the intermitents in not being endemic, although certain localities in the Southern States (Flint) and high altitudes with a low barometer, for the unaccustomed, in some cases predispose to an attack. For the intermitents there is a well-recognized cause which we call malaria, for which we account by more remote but well-understood causes. The aetiology, history, and habitats of malaria are well known, and, therefore, may be avoided; there is no specific cause known for acute pneumonia. The poison for the intermitents is spatial, and all the dwellers within certain limits are liable, sooner or later, to suffer from its influence. This poison also manifests certain well-known types of action, producing, according to its virulence or concentration, congestive, remittent, intermitent fever or dumb ague, besides other well-recognized functional derangements, neuralgias, etc., and it possesses all the characteristics of an infection, inasmuch as it dwells in the system for weeks, months, or even years after its reception. Acute pneumonia is not endemic; there is only one type of the malady, and the cause of the disease does not remain in the system after an attack.

In no aetiological sense does the disease resemble the exanthemata, which have each a period of incubation; each propagates its like and is protective of future attacks, and each has sequelae, in all of which characteristics they differ from pneumonia.

Its unlikeness to epidemic cerebro-spinal meningitis consists in its not being epidemic, in not occurring at the same season, in not being endemic, and in its not confining its attacks to individuals of certain ages.

It is claimed that it is like acute articular rheumatism and is, therefore, an infectious disease due to the action of a morbid agent (Flint, Juergensen, Draper). It is unlike that affection clinically in manifesting a strictly typical course which is cyclical and self-limited, and which terminates by crisis; acute rheumatism, on the other hand, runs an indefinite course, and does not terminate by crisis. The morbid anatomy of the two diseases is unlike. In rheumatism local lesions are not confined to one organ but are changeable; while in pneumonia one organ, the pulmonary, is always affected. We have very clear ideas of the aetiological conditions which cause acute articular rheumatism, and from certain data can predict the disease, while as yet there are no well-recognized signs by which a pneumonic attack can be anticipated. The rheumatic disease, once established, is probably never wholly eradicated, though it may become quiescent. Under certain conditions it will manifest itself, in greater or less effect, throughout life, and is probably hereditary; while pneumonia is most likely due to accidental causes, if not wholly so. Its process once set up, it runs a rapid course, leaves no diathesis, and is not hereditary. The indications for treatment of acute articular rheumatism are well known, clear, and simple, while as yet the therapeutics of pneumonia is obscure considered from a rational standpoint.

Thus, upon no ground of close similarity am I able to understand why acute lobar pneumonia should be classed with the essential infectious fevers.

As the pathology of acute lobar pneumonia embraces, on the one hand, a well-marked constitutional state, among the phenomena of which is notably a clearly defined, characteristic febrile manifestation, and, upon the other, an equally characteristic, well-defined local process, pathologists have sought to determine its nature or true character by seeking to establish which of the two divisions, the constitutional or local, is primary—first in order of development, and therefore essential. Dr. Parkes, loc. cit., discussed this point in 1866, but without reaching a conclusion; although he inclined to give precedence to the fever, for he says that "the assumption that the fever ends because the local disease has terminated is extremely hazardous," thus disclaiming a causal influence for the latter. Dr. William H. Draper, in a paper already referred to, "in 1866" (Flint), also discussed the question of priority, and concluded, with Dr. Parkes, that "the pyrexia antedates the local process pos-
ibly some hours," and, therefore, that the disease is essentially a fever. But, he says, although it can not be answered definitely in regard to this proceeding, yet that presumptive proof would give it to the pyrexia. My own observations of the phenomena of the disease lead me to the opposite conclusion. Although there are cases in which fever has been present some hours, possibly for a day, or longer even, and we are unable to account for it definitely by existing physical signs, yet, even then, we can not say that a local change sufficient to cause the constitutional reaction manifested, although of limited extent and so deeply seated as not to be readily appreciated, has not taken place.

Generally, however, in these cases where the existing temperature rise can not be otherwise accounted for, and there is present also pain or discomfort in the chest, some dyspnea on exertion, a state of nervous anxiety, possibly some hacking cough, a careful exploration of the chest will reveal a local diminished intensity of the respiratory murmur, some scattered moist rales, subepi-ventricular in size, an increase of vocal resonance, and generally a bronchial character to expiration, showing that a local lesion already exists.

Though the clearly appreciable physical signs are sometimes delayed, yet from the foregoing considerations one can not say that there has not existed, from the first moment of the attack, a lesion, though slight, yet of sufficient extent to cause, in the particular case, the irritative or reactive pyrexial expression present. That such sufficient lesion has existed is rendered probable by the following considerations: In no given case can we say how extensive a lesion is required to set up or cause a certain grade of febrile reaction. For, as is stated by Juergensen and observed by many others, there is no exact relation between the local lesion and the general symptoms: "A large consolidation is often formed with slight fever, and, on the contrary, a slight lesion may be attended with high fever." Which lack of relation expressed is the rule.

Again—and this consideration would of itself appear to settle the point conclusively—Juergensen says, "The extension of the local affection to parts of the lung hitherto unaffected is often accompanied by an increase of fever." In my experience, this not only often is the ease, but it is the rule. And that such extension of the local process should be attended by an increased temperature rise is to my mind such evidence of cause and sequence in the relation—cause local extension, sequence fever—as would justify the deduction that in all cases the natural order of events gives precedence to the local lesion. Furthermore, the rapid development of the local lesion, we may say synchronously almost with fever, and in some cases with no or very slight fever, argues against its being a result.

As already stated, it is a part of the theory of the pyrexial hypothesis that the local lesion of this malady is a conservative process by which a morbid material, the active, febrile-making cause, is eliminated from the system. This belief is sustained by the facts that the fever and process of exudation are concurrent, and that defervescence occurs when consolidation is complete—the rationale being that with the maximum of consolidation, or its completion, the poison has been eliminated, and therefore the fever terminates naturally. That the lung may be or is the organ affected by the special poison in this malady, and therefore its avenue of exit or elimination, is held probable by the fact that they are developmentally allied to the glandular organs, through which eliminative effects generally occur. It is claimed that this view is further strengthened by the occurrence of profuse sweating and of herpes in pneumonia, which conditions are commonly associated with disordered blood states.

Profuse sweating and herpes are also often the result of deranged functional disturbances and of febrile states which follow an ordinary cold, and are not more necessarily due to a blood-poison than thermal derangements and nervous conditions. Their occurrence in this malady is probably the result of an elevated temperature, combined with the singularly deranged circulatory and respiratory conditions which result. This opinion is justified by the fact that herpes, especially, occurs in cases where the temperature has been highest.

The question now arises, Does the lung, or, more exactly, that portion of it which is involved in a single case of acute pneumonia, perform the office of a special emunctory in this malady? Beyond the following facts—namely, that the lungs are embryologically allied to the glandular organs, that they are the seat of the local manifestation of this disease, and that pneumonia, as a whole, comprehends two separate and well-marked sets of phenomena, rendering the disease in this respect similar to the infectious diseases—there is no ground for maintaining that the involved organ performs such emunctory function; on the contrary, there is much to render the fact of such an office most improbable.

Against such action it may be stated, at the beginning, that the existence of a poison to be eliminated is entirely a matter of speculations; the affirmation of which is greatly weakened by the acknowledgment that it is both unknown and has not been traced by chemistry or otherwise. In the more complete determination of this point, however, there are several questions relative to the possibility of this local process being eliminative in character, answers to which must conclusively negative the ground of such action:

First. If such an office is performed by the lung, why should this extraordinary function fall upon a single lung, or upon a fraction of an organ, instead of upon both lungs? And why should the lower lobes and the lower lobe of the right lung be its favorite seat?

One of the characteristics of the action of a blood-poison in the system, and especially of the local action it sets up, is its diffuseness. In this malady we have not a diffuse action throughout the lungs, but a strictly local process. This argues against deparative action; besides, it is more reasonable to suppose that, if a poison were being eliminated by the lungs in this process, both lungs, and many foci in both, would be the seat of its local manifestations. The pneumatic process being particularly local, and its extension from one region being the rule, not only argue against a general cause present in the blood, but make the existence of such cause extremely problematical. We shall see, later on, that this localization of the pneumatic process, and the tendency of its attack, of its site, to be somewhat special as
Hospital Service in 1881, is the most complete of anything in existence, to which I refer readers desiring to look up the subject in extenso.

It has been already mentioned that the discovery of the astrological connection between trichiniasis of the hog and of man was first made by Dr. Zeuker, of Dresden, in 1860, in the case of a servant girl that was admitted to the City Hospital at Dresden as a typhus patient. She died! her muscles were found completely infected with the parasite. At the same time she was taken sick, others of the same family, and the butcher who slaughtered a hog for them, were ill also, but their sickness presented a modified form in comparison to that of the girl. An examination of the pork eaten from, and remaining, revealed the presence of numerous trichines.

Thudiehann * sums up the principal phenomena of trichiniasis in man as follows: "Sudden swelling of the face, particularly of the eyelids, after the patient has for some days felt prostrate and lost appetite; the swelling causes a sense of tension, but no pain; fever, quick pulse, copious perspirations, which not rarely have a repugnant odor; painfulness and immobility of the arms and legs, which give great pain on being moved or pressed severely; in the worst cases, the entire body is perfectly inmovable and highly sensitive; there is diarrhoea; a red, somewhat coated tongue, inclined to dryness; when the swelling of the face has subsided, oedema of the feet, legs, and thighs comes on. Shortly afterward anasarca and swellings over the trunk make their appearance."

From the time of Zenker's case numerous others have come to light in different countries.

Epidemics have been reported at different places in Germany, the most remarkable of which was that at Hedersleben, a little place of 2,000 inhabitants, of whom 337 became sick at one time, and of this number 101 died.

The discovery of trichinae in human beings at the excretion of tumors has been previously mentioned.

Forty persons were sick with trichiniasis at one time at Bremen, from, it is said, eating American pork.

At Lissa five members of one family became infected from eating a ham which had been pickled, smoked, and then boiled for two hours.

A poor woman derived the disease from eating the flesh of a dog, to which her necessities had driven her.

Dr. Kiefer (Detroit) reports a fatal case of trichiniasis.

Dr. Herr (Dubuque, Iowa) reports 15 cases with 5 deaths.

Several cases are reported in the "American Journal of the Medical Sciences," Philadelphia, Pa.

In January, 1881, a case occurred at Blackwell's Island, N. Y.

Two cases were reported at Chicago the same month, and two at Milwaukee.

Dr. Germer, Erie, Pa., reports (private letter, January 27, 1881) that the preceding Christmas he discovered seven cases, in a place eight miles distant, which were traced to the eating of home-fed and cured pork.

The most interesting American case is one which occurred at Brooklyn, N.Y., in September, 1879. Seven of a family became ill with trichiniasis, two of whom died. A lawsuit was the result, the family suing a packing-house from which they had purchased a part of a ham some days previous to the eruption of the disease. As they had been continually in the habit of eating raw ham and sausages, and as they had purchased the ham only two days previous to the first appearance of pathic phenomena, it was self-evident that the plaintiff did not have any case, especially as no microscopic examination of the ham had taken place. Further, it is not possible to look upon retailers of pork as responsible for its being free from trichina in a country where neither the law nor the community recognizes any such disease of pork. Even our boards of health simply recognize the existence of trichinae in pork as a scientific fact. All of the hogs, trichinous or not, which I examined portions of, were cut up, packed, and sold, although the Massachusetts Board of Health was perfectly well aware of the results of my daily examinations.

Until the consuming public becomes alive to its own interests, we may be positively sure that no steps toward prevention will be taken by any local or State authorities.

A German judge has ruled differently, declaring a provision dealer "guilty" who had sold trichinous pork, although the same had been subjected to microscopic examination; the pork had been eaten by several persons, causing sickness and, in one case, death.

Dr. Sutton,* Aurora, Ind., reports nine cases of trichiniasis, with three deaths, the persons having eaten smoked sausages; examination of the remainder of the sausages revealed the presence of trichinae. A cubic inch of flesh taken from the body of the person that died was estimated to contain one hundred thousand trichinae.

Dr. Sutton says that "the microscopic examination of thousands of swine slaughtered in Indiana revealed 3:16 per cent. of them to be infected with trichinae. This is an unfounded statement, there being at the time no record of the examination, either of "thousands" or of a single thousand hogs.

The "Rochester Democrat" of May 1, 1879, reports several cases of trichiniasis in that vicinity. Others may be found in the State Board of Health reports from Michigan.

Many of the cases mentioned in the daily papers as trichiniasis may be as reliable as the remainder of their information on kindred subjects.

A very interesting case of trichiniasis, among a large number of people at a village on the Jordan, is mentioned by Dr. Wortabet,† It was due to the consumption of the head and portions of a wild hog.

Trichinae have been very frequently found at the dissecting-table in the flesh of man.

Prevention of Human Trichiniasis: 1. Exact microscopic examination of pork before the animal is allowed to be cut up for packing or retailing in any way.

Cook thoroughly until the piece of pork is really done all through.

American and the Italian publication, both being as close approximations to the absolute as one could reasonably expect. In mechanical execution and general make-up the American books are perhaps the superior, as they certainly are in size and in the abundance and diversity of matter which they contain.

The chief points of difference between them, it will be seen, lie in their aims, the dispensatories being addressed rather to the pharmacist, the *Pharmacopoea* to the therapist; and in their special lines all of them, it need scarcely be said, will be found to be of very great value as books of reference.

This work is one that is well worthy of a careful perusal, though not requiring close reading. After giving a skillfully drawn outline of the state of medical practice in the times of Cato, the censor, at Rome, its uses and abuses, the restrictions placed upon it, and the privileges accorded to it from that time onward, the author proceeds to give an account of the advance of scientific methods of practice by the geniuses who first drew medical science from empiricism to principle, its practice being divided into various branches, and each studied and explained, as far as could be done at that time, by the thinkers and observers Agathinus, Areteus, Celsus, Galen, and others. He then treats of medical schools, in Alexandria especially, as thence extending to all the parts of the Roman Empire; the Arabic influence on this, to them new, science; German, Gallic, and Spanish cultivation of medical art; the effect of Pagan and Christian ideas upon its practice; the belief in magical, mystical, and demoniacal agencies; the decline and rise of the art in different times and under various influences; the status of medical men in the Middle Ages; and the intelligent aid extended by different great men at critical periods.

We have endeavored to show by this brief summary that the work is not one meant only for professional or scientific readers, but eminently one for the intelligent of all classes. Its style is easy and clear, and it is pleasant to read a work involving so much research and, at the same time, so methodical in arrangement. Nor does the author fail to give due honor to all of any nationality who, in their respective ages, assisted to make clearer, purer, and stronger the light from the lamp of intelligence. All—Arab, Italian, Spaniard, Frenchman—are honored in due proportion. The most entertaining part of the work, in our opinion, is the brief yet lucid account of each locality as affected by its surroundings and previous culture.

Is Consumption Contagious, and can it be transmitted by means of Food? By HERBERT C. CLAPP, A.M., M.D., Professor of the History and Methodology of Medicine, etc., in the Boston University School of Medicine, etc. Second edition. Boston: Otsis Clapp & Son, 1882. Pp. 197. [Price, 75c.]

This work seeks to establish upon a clinical basis the contagious character of all varieties of phthisis. Under consumption the author includes every form of phthisis, and under the term contagious he expresses indifferently either infection or contagion. With the many thousand annually dying of phthisis we should suppose that a work which sought to establish such a hypothesis (as we will for the present term it) should rest for its argument upon many hundreds if not thousands of carefully noted cases. It is somewhat surprising to find that the main deductions of the book are drawn not from an unbiased review of many hundred cases, which the author had at his disposal, but from twenty-five, carefully selected from among the former number, which seemed most favorable to his theory. He evidently starts with a theory, and then looks for premises to base it upon, the reverse of our usual methods of scientific procedure.

With pleasing candor he reviews historically the opinions of the ancient and older and recent writers upon the subject of the transmissibility of phthisis. Here we find side by side arguments as strong against as those favoring the theory of contagion. In a succeeding chapter the author speaks of cases of contagion of tuberculosis among cattle, as shown by their contracting the disease under good hygienic surroundings in well-ventilated stables, when placed in stalls previously occupied by diseased cattle.

After a recital of the twenty-five cases already alluded to, the author rapidly makes his deductions: First, strongly favoring contagion; secondly, that the period of incubation must be weeks, months, and even years; and, lastly, that all ages are susceptible.

Interspersed with these deductions we are met by such arguments as these: Hereditary transmission will not account for all the cases; "the majority must therefore have been acquired, and how?" to which the author replies, As likely by contagion as by any other means. He then answers the objections to his deductions. He states that simply because the causal relation between the contagion and the subsequent disease can not always be traced, and because a comparatively small number may be attacked in this way, is no argument against the theory. He cites the varying susceptibility to the other well-recognized contagious diseases. To quote the author's words: "For this reason, even if the number of recognized cases of consumption produced by contagion is quite small, we need not on that account abandon the doctrine, but admit that it may be contagious to a slight extent and under certain conditions." Next, the author dwells upon the probability of infection from tuberculous food, such as the meat or milk of diseased cattle, arguing from experiments upon the lower animals and suggesting that food may transmit the disease. The inoculability of tuberculous matter and the experiments of Cohnheim and others are referred to. Finally, in an Appendix, we have an allusion to Koch's more recent discoveries of the tubercle bacillus. As the publication of these discoveries succeeded the time of the writing of the book, the author has been unable to make use of it in the body of his work. We regret it all the more, as it would have furnished him with the most important argument in favor of the theory of contagion.

In the light of a journal article or an essay before a medical society, seeking to call attention anew to the contagiousness of phthisis, the author's work would have appeared justifiable and highly creditable; as a book for the public, we must say that his deductions are not proved, though our opinion leans toward the one the author seeks to establish.

BOOKS AND PAMPHLETS RECEIVED.

The Mineral Springs of the United States and Canada, with Analyses and Notes on the Prominent Spas of Europe, and a List of Seaside Resorts. By George E. Walton, M.D., Member of the Société Française d'Hygiène, Paris; ex-President of the Academy of Medicine, Cincinnati, etc. Third edition, Revised and much Enlarged. New York: D. Appleton & Co., 1883. Pp. xvi—468.

BATTEY'S OPERATION.

N OSSKNSHOLM as the term "normal ovariectomy" was, it was generally understood that its author, Dr. Robert Battey, intended it to signify the operation of removing the healthy ovary—in plain English, spaying. At the same time it was evident that in a number of Dr. Battey's earlier cases the ovary was not healthy. By common consent, the ridiculous expression we have mentioned was soon given up, and the procedure in question came to be known as Battey's operation, or "oophorectomy." The strict meaning of the latter word affords no justification for limiting it to any particular form of the operation of removing the ovary, for it is quite as applicable to the removal of an immense cystic ovary as to excision of the normal organ. Nevertheless, it may come to be regarded as practically the best term for all operations that consist essentially in extirpation of the ovary for other reasons than the existence of ovarian tumors, restricting the mongrel word ovariectomy to the removal of such tumors, since it has for many years been used so generally in this sense as to have become fixed in our literature.

Although there was originally no other justification for the term Hegar's operation than a laudable disposition to give its promoter the credit of having arrived independently at the conclusion that certain good results were to be reached by removing healthy ovaries, yet the term has been so carefully restricted to the operation done with the definite purpose of withdrawing the physiological ovarian stimulus from the uterus, and so putting a stop to the growth of tumors of that organ, that it is likely to hold its place in nomenclature, whatever our ideas may be as to the precise erudition for originality that should be awarded to Battey and Hegar respectively. So, too, what has lately come into vogue under the title of Tait's operation—meaning the removal of what that surgeon terms the uterine appendages, particularly the Fallopian tubes—seems to have a distinctive purpose quite apart from the ablation of ovarian function, and therefore can not properly be classed as a variety of Battey's operation.

Strictly speaking, there appears to be nothing left to which the latter term can be explicitly applied, except oophorectomy for the relief of ovarian neuralgia, including ovarian dysmenorrhea, and certain derangements of the general health reasonably referable to such diseased states of the ovary as are not of much importance from a surgical point of view. In Dr. Battey's latest publication on the subject, in the August number of the "Virginia Medical Monthly," brief notes are given of eight cases of "Battey's operation." It is noteworthy that the ovaries are not expressly stated to have been found healthy in a single one of the eight, although it seems probable that such was the case in one of them. In one or two of them, indeed, the organs were found profoundly altered, with implication of the oviducts, generally in the form of cystic degeneration or cyst-like dilatation.

It is evident that in such cases the real ground for removing the organ is not to do away with its function, and yet it is to be inferred that Dr. Battey regards the artificial induction of the menopause as of prime importance, for he plainly states his disinclination to stop short of the removal of both ovaries, even if only one of them is found diseased—a feeling that is the result of his experience.

On the other hand, it is remarkable that so much stress is laid on the slow progress of the improvement that is to be looked for after the operation. In one instance it is noted, twelve months after the removal of the ovaries, that the patient was much improved in every way, but not entirely well yet—the diagnosis having been recorded as "chronic uterine disease for ten years, with oophoralgia which has resisted all treatment," and both ovaries having been found diseased; and the statement is made, "She will continue to improve for a year or two more." Surely, the function of an organ must cease at once on its removal, and it is difficult to see how a result that takes two or three years for its accomplishment can properly be set down to the discontinuance of a function that was stopped in an instant. It is curious to contrast the case referred to with another, in which, three months after the operation, the patient was "much improved," but, when she was last heard from, "the time was too short to indicate final results."

From these considerations we are led to infer that Dr. Battey regards his operation as including all oophorectomies except those to which the term ovariectomy is commonly applied. If this is the case, he can scarcely admit the propriety of classing Hegar's operation by itself, or Tait's, either, since it is his practice also to remove the Fallopian tubes whenever he finds them diseased, and with quite the same objects in view as those aimed at by Tait. The profession must either accept this view, or limit the originator of the operation to a residual field, definable only by comparison—a restriction not easy to reconcile with the broad scope at first laid down for oophorectomy by Dr. Battey.

CHARITY HOSPITAL.

While all the attractiveness of its situation, and its fair architectural appearance, there was a time, and that not long ago, when the sick poor looked upon Charity Hospital with loathing, when to be sent "to the island" seemed to them a disgrace little short of that attaching to incarceration, and when medical men regarded the institution as of no particular educational importance, but rather as a revolting sort of curiosity shop, where nothing was exemplified but the ravages of misery and vice—a concentration of what they already saw enough of in their daily rounds.

Both classes were amply justified. The patients had come to feel that the island was a lumber-room to which nothing in the shape of disease was sent, unless of an infectious nature or else so utterly devoid of interest as to be thought fit only for a
THE DECAY OF HOSPITAL TEACHING.

It is to be feared that the modern amplification of the technical element in medical practice has not been altogether free from a certain pernicious effect, notwithstanding its great advantages on the whole. That it has rescued a great proportion of chronic invalids from the limbo for incurables there can be no doubt, or that ipso facto it has exalted medicine in the eyes of the world. We may concede, too, that, as a direct result of its action in this direction, it has heightened the devotion of physicians to their art, and drawn into the profession a great number of able men who, but for some such elevation of medicine, would have chosen other callings. In the main, therefore, it is beyond question that the descendant reached of late years by the manipulative phase of therapeutics has been benificial. It seems open to doubt, however, whether our system of teaching tactics in the presence of acute disease has not been clogged as the result. It is but a few years ago that chronic diseases of almost all sorts were reckoned among the appretria medicorum; now they are hunted down with so much ardor, and with such a multifarious enginery, that there really seems to be some danger of such commonplace affairs as fevers and phlegmasias, to say nothing of the diatheses, playing the part of the tortoise to our hare.

Why do men feel doubt as to the real nature of the present visitation of pestilence in Egypt? Why does it remain for weeks a matter of uncertainty whether such and such an outbreak is really one of yellow fever or not? Why are people with the measles sent to small-pox hospitals, and others quarantined for acne? Such things happen far too often, and yet men acquire dazzling skill in "physical" diagnosis and grow wonderfully expert with all sorts of instruments. It is to be feared that this state of things is due in great measure to the fact that medical students, and those practitioners who resort to the great cities for supplementary instruction, have been dazed with the glamour of these fine accomplishments. It is the students that are at fault, for the teachers know well enough that it is general medicine that most needs to be dinned into the ears of the pupils, and that it is the ordinary run of fevers and the like, such as are to be found by the score in our hospitals, that should claim their chief attention; but, while they use all possible means to lead students to this path, they are met with deaf ears, except when the matter is one that has to be learned in order that an examination may be passed.

No doubt it is more attractive to pass one's time in striving after manual dexterity than in the more homely study of constitutional conditions, and to this fact we may impute the growing neglect of the good old habit of "walking the hospitals." It must be allowed, indeed, that the latter was often carried out in a perfunctory way, but none the less is there reason to think that the systematic study of cases of acute disease day after day would make men really good practitioners with far more certainty than any amount of manipulative training.
DO MORAL PRINCIPLES CHANGE WITH TIME?

When our esteemed contemporary, the "Journal of the American Medical Association," put this question to the world several weeks ago, we did not anticipate that we should be able to give an early answer in the affirmative, with an example from the sanctity of its own household." To be sure, the "household" has in times gone by furnished us with convincing evidence that in its opinion moral principles do change as the ages roll on, but just now the brethren are on their good behavior. "These be parous times," and therefore it can not reasonably be expected that the lavatorial operations to which dirty linen requires to be subjected will at this particular epoch be performed before the gaze of a scrutinizing public.

But it seems there is at least one medical society in "good ethical standing" which believes not only that time is a soother of sorrows, as every one knows it to be, but also that it is able to convert a blood-curdling offense against the code into an act of such innocuousness that babes and sucklings, members of the association, and even an ex-president of that august body, would not be contaminated by its perpetration. Now, as every one knows that all offenses against the code are inherently immoral, the importance of this new therapeutical discovery can not be overestimated, especially as it is at the same time a complete answer to our contemporary's question.

It seems that a brother, whom we will call Dr. A., was desirous of becoming a member of the District Medical Society of Northwest Missouri, and that two other brethren, Dr. B. and Dr. C., were instrumental in so "fixing" matters that he was blackballed, on the ground that he had in some horrible manner violated the code. What he had done we are not permitted to know, but it must have been something perfectly dreadful, for never can we write the letters M. D. M. S. N. M. after his name, whether on sign, card, or title-page.

But Dr. A., instead of taking his punishment with becoming lamb-like meekness, turns upon his two enemies, who are told, are "prominent physicians of St. Joseph," and, notwithstanding the fact that they have been actuated by the highest ethical (and, of course, "moral") principles, proceeds to show that it is a fresh case of the pot calling the kettle black. Although not an adherent of the tu quoque line of argument, we must confess that occasionally it is not without a certain amount of force. He showed that Dr. B. had circulated a professional card on which was an engraving of the building in which he had his office. Whether it also represented the people of St. Joseph, "the sick, the halt, and the blind," rushing in crowds to the door in order to receive as soon as possible the professional advice of a highly ethical and moral physician, we are not informed. That it ought, in order to be fully effective, to have possessed this additional embellishment, is very clear. Half-measures are always indicative of weakness. This card, it seems, was "submitted to a prominent member, and an ex-president, of the American Medical Association for his opinion, who said that he knew of no rule of the code which it violated"—which is about as correct as if he had said that there was no rule against a physician's going through the streets dressed in velvet and spangles, beating a drum, blowing a horn, and inviting the afflicted to come up and be cured. It is a very good code, but it does not prohibit these things.

Dr. A. also brought to light the card of Dr. C., which, besides setting forth his professional qualifications, exhibited the portrait of Jesse James, the eminent highwayman and murderer. What the connection may be between the practice of medicine and the portrait of Jesse James passes our comprehension, but perhaps the mystery is solved by the fact that Dr. C. issued this card "when he was running for the office of coroner," and presumed that propitiating Mr. James might lead that worthy to provide him with plenty of official work. We have heard of cases in which the portraits of saints have cured the ague, the small-pox, broken legs, etc., but that the likeness of a notorious criminal should be potent in politics is certainly a new fact in sociology.

However, there are deep questions, of which we must defer the consideration. Dr. A. brought his charges, and exhibited his documents in their support; but, notwithstanding the establishment of the additional offense that "their names had been used as a testimonial in favor of a sewing machine," Dr. B. and Dr. C. were triumphantly acquitted, and on the ground that the deeds with which they were charged were "committed some years ago." Thus we see that moral principles do change with time, and thus is our contemporary answered before the ink is fairly dry in which its query is printed.

MINOR PARAGRAPHS.

THE STATUS OF THE SURGEON-GENERAL OF THE NAVY.

The Surgeon-General of the navy stands on a different footing from the officer of the same designation in the army, since he is not appointed to serve for an indefinite term, but for the period of four years, being in a certain sense detailed to the position, with the temporary rank of commodore. This fact is of interest in connection with a contention that seems to have arisen between the friends of the present incumbent, Dr. Wales, who maintain that his term of office does not expire until four years from the date of his commission, January 20, 1859, and his opponents, who affirm that he really ceased to be Surgeon-General on the 1st of August, four years from the date of his original appointment.

We are unable to see any flaw in the view held by the Surgeon-General's friends, and it is to be hoped that the bickering to which his appointment gave rise will not be carried to the length of an attempt to test the legality of his present tenure by an appeal to the Attorney-General, which rumor reports has been threatened. Nothing but entirely worthy motives can be ascribed to any gentlemen of the medical corps for aspiring to the office, but it will be an occasion for regret if they allow themselves to sanction such a petty policy as that we have alluded to.

THE NORRISTOWN ASYLUM HOMICIDE.

At a recent investigation before the Board of Trustees, one of the physicians of the institution stated that his assistant inspected the patients in the morning, and that he himself acted as a consulting physician, adding that they "attended to all cases worthy of consideration"; whereupon one of the trustees
DEATH FOLLOWING THE BITE OF A SPIDER.

An old gentleman living in Columbia, S. C., is stated to have died last week of erysipelas starting from the bite of a spider. Some interest has lately been taken in the fatal results that sometimes follow the bite or sting of insects not usually accounted venomous, and we have drawn attention to two or three cases of death imputed to the sting of the bee. In regard to this spider case, little importance is to be attached to it, as erysipelas may start from any wound.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending August 28, 1883:

| The cases alluded to in our last report as having been detected in a sailors' boarding-house in the village of Woolsey, near the Pensacola Navy-Yard, proved to be those of some deserters from a vessel that had come from Limerick with a clean bill of health, and had not been quarantined. She cleared again the day the men reached the boarding-house, the 17th of August, the deserters having spent three weeks in a ramble up the bay. It does not seem likely that they brought the disease with them. Passed Assistant Surgeon D. M. Gutierrez, of the navy, volunteered to go on duty at the Pensacola Navy-Yard last week, and was ordered there at once.

On Wednesday of last week a steamer left Vera Cruz and Havana reached the New York quarantine station, where she was detained, one of her engineers having been sick on the voyage, it was supposed with yellow fever. The passengers were allowed to come up to the city on Saturday.

On Friday, August 24th, a bark arrived at Portland, Me., from Vera Cruz, having had yellow fever on board. She was quarantined at Portland.

On Saturday, the 25th, the town of Pensacola was officially declared to be perfectly healthy, and its condition as to cleanliness excellent with the exception of a few houses. The people of the town had taken courage, and some of the neighboring towns had shown their confidence in the official report by removing the restrictions they had imposed on intercourse with the place. The same day three cases were reported from the navy-yard.

On Monday, the 27th, Mrs. Owen died, and her second daughter was attacked. At that date the marines were reported to be free from the disease.

On Tuesday, the 28th, Paymaster Brown died.

On Wednesday, the 29th, it was reported that all the fever patients were doing well, and that the town of Pensacola was still perfectly healthy.

Our Vice-Consul at Aspinwall telegraphed to the State Department, on the 27th of August, that that port was free from yellow fever and that the town was in good sanitary condition.

The foregoing facts go to show that the energetic action of the Marine-Hospital Service, the medical corps of the navy, and the local sanitory officials seems to have been successful in checking the spread of the disease.

CHOLERA.—The disease has continued to decline steadily in Egypt, the daily number of deaths having fluctuated between eighty-one and two hundred and twenty-six for the whole country. On Sunday the disease was reported to have broken out in Sumatra.

THE STUDY OF THE CHOLERA IN EGYPT.—We have heretofore spoken of the French commission, under the direction of M. Pasteur. Another French investigator, M. Jules Aronssohn, of Paris, the professor of organic chemistry, is commissioned for the same purpose, and a German commission headed by Dr. Koch has set out for Alexandria.

TYPHOID FEVER AT RYE BEACH, N. H.—On Friday of last week the news reached New York that there was a good deal of sickness among the summer visitors at Rye Beach. It was at first supposed to be malarial, but it has since been shown satisfactorily that it was typhoid fever, due, it is thought, to the percolation of refuse matters into the drinking-water. Several deaths have resulted, but it is announced that the defects of drainage have now been remedied.

INFECTIOUS DISEASES OF DOMESTIC ANIMALS.—The Treasury Department has issued a circular to collectors of customs in which the following instructions are contained: "By Department circular of July 30, 1883, it is provided that 'Where there are more cattle for quarantine than the regular Government stations can accommodate, special arrangements for quarantine outside of the stations may be made by the collector of the port where they arrive, upon consultation with the Cattle Commission or the superintendent in charge.' You will observe that the responsibility in this matter rests upon the collector of the port in whose immediate custody the quarantine stations and the cattle therein are placed. While it is desired that the collector shall be in constant communication with the Cattle Commission, and that he should act in harmony with their views, he will not assume to make orders with regard to the cattle; and this Department will issue no instructions respecting the quarantining of cattle or for their transfer from one station to another or to any other place, except through the collector of the port. Where stations are crowded, the Department will rely upon the collectors at the respective ports to make such arrangements for quarantining cattle outside of the stations as the circumstances of each case shall seem to require.'

Several valuable cattle are reported to have been poisoned at the Boston quarantine grounds from drinking water impregnated with Paris green that had been sprinkled over the ground at a time when it was used as a potato field.

A number of cattle that were recently taken from Montreal to Liverpool have been slaughtered at the latter port, as it was suspected that they had been infected with "Texan fever." The "hog cholera" is said to have broken out in the northern part of Alabama.

A Nurse's Mistake caused the death of a patient in the Blockley Hospital, Philadelphia, last week. The patient was an epileptic, and, as a paroxysm was threatened, a nurse hastily seized a bottle from a closet, and gave the man a draft of what he supposed to be a solution of bromide of potassium, but which turned out to be carbolic acid.

A Brooklyn Abortionist.—One Mrs. Furlong, of Brooklyn, is under arrest, charged with having caused the death of a Miss Charity Lewis, by an operation practiced for the purpose of producing an abortion. The coroner's jury found that the young
woman's death was due to metro-peritonitis. It is said that Mrs. Furlong admits having done the operation not only in this case, but in several others also. Dr. S. S. Doty was at first charged with complicity in the crime, but the evidence does not seem to have been sufficient to hold him.

The Nursery and Child's Hospital.—Dr. Francis H. Markoe has been appointed on the visiting staff, in place of the late Dr. Livingston.

The Presbyterian Hospital.—A new pavilion, with room for twenty-eight beds, is expected to be ready for use in about a month.

The Hartford Hospital is reported to have had bequeathed to it, by the will of the late Mr. David Gallup, property which it is thought will exceed $20,000 in value.

A New Lunatic Asylum in Toledo.—It has been decided to build the new Ohio State asylum on the outskirts of Toledo. One hundred and fifty acres of land have been obtained for the purpose, and the cottage plan will be adopted. It is said that the non-restraint system will be enforced.

The University of Berlin.—Professor Waldeyer, of Strassburg, has been appointed to the chair of anatomy, to succeed Professor Reichert.

The University of Prague.—Dr. Hans Chlari has been appointed professor of pathological anatomy.

Sir Spencer Wells, says the "British Medical Journal," has been elected an Honorary Fellow of the Physico-Medical Society of Erlangen.

A Physician Shot for Refusing His Services.—At Hoosick Falls, N. Y., Dr. F. R. Hudson was shot last week by a man whose wife he had declined to visit. The wounds are reported to be serious.

OBITUARY NOTES.

Surgeon Alfred M. Owen, of the Navy.—Dr. Owen entered the medical corps of the navy in 1869. His last station was the Navy-Yard at Pensacola. In our last issue we gave an account of the outbreak of yellow fever at that station, and mentioned that at the time of our going to press Surgeon Owen had been prostrated with the fever, and was in a very critical condition. He died on Thursday of last week, at about the time the article referred to was written. One of his children was among the first victims of the outbreak, dying a few days before her father; Mrs. Owen has succumbed to the same disease since her husband's death; and now another child has been seized with it. Such a tale of woe, while it attests the devotion to duty called for from officers of the staff, and rendered by them, as well as those of the line, ought to go far toward blotting out the rancor felt by line officers of the navy for those they are fond of speaking of as "non-combatants." Dr. Owen's life was lost as truly in the line of duty as if he had had command of a ship, and been killed in action; and the profession may say of him and of his devoted family, hac mea ornamens sunt.

Assistant Surgeon William Howard King, of the Army.—Dr. King died at his home in Philadelphia on Thursday, the 23d instant, in his forty-third year. During his service in South Carolina with the Union forces he contracted a disease of the bowels from which he never fully recovered, and his death was due directly to peritonitis. In May, 1865, Dr. King was appointed Assistant Surgeon of the 149th Pennsylvania Volunteers, and in August of the same year was appointed to the 21st Pennsylvania Cavalry as Surgeon with the rank of Major. November 16, 1868, he was commissioned First Lieutenant and Assistant Surgeon in the United States Army, and in October, 1869, was promoted to the rank of Captain. Early in 1882 his health compelled him to relinquish his duties at the station in Dakota, where he was serving, and he returned to Philadelphia, where he remained until his death.

Horace Poole Wakefield, M. D., of Leicester, Mass.—Dr. Wakefield died on Thursday, the 23d inst. He was born in Reading, Mass., January 4, 1809, and received his preliminary education at Bradford, Mass., and at the Pinkerton Academy, Derry, N. H., and in 1822 he was graduated from Amherst College. He received his Medical Degree at Dartmouth College in 1836 and settled in Oakham, Mass., where he remained until 1844, when he moved to Reading and continued the practice of medicine there until 1866. In 1870 he removed to Leicester, where he remained until his death. Dr. Wakefield was prominently identified with the interests of the towns in which he resided, having held various public offices, being elected to the Legislature from Oakham in 1843-'44, and State Senator from the Fifth Middlesex District in 1862-'63. He held the office of Inspector of the State Almshouse at Tewksbury in 1864, and from 1866 to 1868 he was a physician in that institution. For nine years he was Superintendent of the State Primary School at Monson, Mass. He was at different times a Councillor of the Massachusetts Medical Society, President of the Middlesex East District Medical Society, and ex-officio Vice-President of the Massachusetts Medical Society, before which he delivered the annual address in 1867.

Mrs. Mathilda C. Ayerton, M. D.—Mrs. Ayerton died in London on the 19th of July, at the age of thirty-seven. She and Mrs. Elizabeth Garret Anderson attempted to gain admission to several English colleges some years ago, but, being repulsed, returned to Paris, where they were welcomed at the school of medicine. The deceased wrote several books of travel, and was an ardent advocate of the co-education of the sexes.

Letters to the Editor.

The Sanitary Council of the Mississippi Valley and the Louisiana State Board of Health.

Sanitary Council of the Mississippi Valley,
Office of the Secretary, Springfield, Ill., August 13, 1883,

To the Editor of the New York Medical Journal.

Sir: I beg to call your attention to the following, without any comment other than the remark that nowhere in my report is there any claim that the Sanitary Council has done anything more than supervise the inspections formerly maintained by the National Board of Health.

Extract from report of proceedings of the Louisiana State Board of Health, at its regular meeting in New Orleans, August 9, 1885:

In relation to a report of Dr. John H. Rauch, secretary of the Sanitary Council of the Mississippi Valley, to President Hadden, published in one of the Western journals, Mr. Booth offered the following resolution:

Whereas, It appears that Dr. J. H. Rauch, of Springfield, Ill., signing himself as Secretary Sanitary Council of Mississippi Valley, has made a report to President Hadden, of Memphis, wherein it is stated that the late National Board of Health and the present Sanitary Council of the Mississippi Valley have so successfully conducted the Louisiana and Mississippi quarantine during 1883 that it is no longer necessary for a sanitary council inspector to remain at said quarantine, and that, consequently, said inspector had been withdrawn, with much other alleged information touching the conduct, statistics, management, and
Proceedings of Societies.

American Association for the Advancement of Science.

The thirty-second annual meeting was held at Minneapolis, Minn., August 15 to 22, 1883, the President, Professor C. A. Young, of Princeton, N. J., in the chair. For the most part the proceedings had no bearing upon medicine, and our summary will therefore be brief.

Conscious Automatism.—Dr. Charles P. Hart, of Wyoming, Ohio, read a paper in which he stated that it was not his object to discuss cerebral automatism in all its relations, but only with reference to man, and that, too, in a single particular. The question he endeavored to answer was: "Are the higher automatic actions in man—that is, actions which are usually of a voluntary character—ever entirely and exclusively automatic? In other words, when the organ of mind—the cortical substance of the brain—is present and in a normal condition, do the higher automatic actions—those which usually display intelligence—ever take place wholly independent of, or uninfluenced by, that organ, as taught by Carpenter, Althus, and other leading physi-
ologna of the day?" After quoting the illustrations given by the last-mentioned author in the "Nineteenth Century" magazine for December, 1879, he maintained that, in the cases cited, the cerebral centers influenced the so-called automatic movements to a greater or less extent; otherwise, when a certain succession of acts was to be performed, there would be nothing to limit and define them as a whole, i.e., as a series, or to separate them from others of a similar character, which, from habit or education, had become equally automatic. Various illustrations were then given, special reference being made to the two forms of aphasia, the ataxic and the anemic, the anatomical and physiological basis of which, the author thought, fully confirmed his views.

He then quoted from Ferrier to show that destruction of the cortical motor centers in man caused such complete and enduring motor paralysis as to indicate that automatism in and by itself was scarcely detachable from the centers of consciousness and volition. Illustrative cases were then given to show that when the mind was so intensely occupied in thought as to be almost entirely withdrawn from the automatic action performed by the lower centers, mistakes were frequently made, the "absent-minded" person running against objects when his eyes were wide open and his vision was unobstructed, going into the wrong house, and committing other like errors.

The author then took up the phenomena of somnambulism, which were supposed to prove the correctness of the received theory of perfect uncontrolled automatism, and showed that instead of lending any support to the theory of independent ganglionic automatism, they were directly antagonistic to it, since the mind of the sleep-walker was intensely active, and governed his movements in the most perfect and pronounced manner.

In short, to sum up the whole matter, the author reached the conclusion that the cortical substance of the brain, when normally present, was, in the case of man, seldom or never without influence of some sort or degree upon the automatic centers.

The Use of Vaseline to Prevent Loss of Alcohol from Specimen Jars.—In a paper with this title, by Professor Bert G. Wilder and Dr. Simon H. Gage, of Ithaca, N. Y., attention was called to the fact that the petroleum preparation termed vaseline was known to be practically unaffected by ordinary temperatures and by most substances. In the "Journal" of the Chemical Society for July, 1882, p. 785, it was said to be sparingly soluble in cold, strong alcohol, and completely in hot, but to separate out on cooling. After trying various substances—wax, paraffin oil, and glycerol—with but partial success, the use of vaseline was suggested by the two authors independently and nearly at the same time. The experiments tried last spring indicated that during three months, at ordinary spring and summer temperatures, there was no appreciable loss of 95-per-cent. alcohol from glass phials or jars, whether upright or inverted or on the side, provided the corks were smeared on the bottom as well as on the side. Ground-glass stoppers were anointed and firmly inserted, and the rubber rings of fruit jars and the specimen jars made by Whitall, Tatum & Co., were coated on both sides and the covers well screwed down. The authors had also used the vaseline for preventing the loss of other liquids, including chloroform and oil of turpentine; as a lubricator of drawers, and to prevent the sticking of the covers or stoppers of cement phials; and for the prevention of rust upon steel instruments.

Anesthesia with Nitrous Oxide and Air, or Nitrous Oxide and Oxygen, under Pressure.—Dr. E. P. Howland, of Washington, read a paper in which he embodied the conclusions derived from a large personal experience with M. Paul Bert's method of using nitrous oxide as an anesthetic, and demonstrated the process. He believed that the plan would yet supersede the use of ether and chloroform. The reason why nitrous oxide, as ordinarily administered, could not be used for prolonged operations was, that the blood could get no oxygen from the agent, for it was expired unchanged, so that asphyxia was produced. Pure nitrous oxide, therefore, could never be made practicable for long operations. In the author's experiments with it on animals, death generally occurred in two minutes and a half. If air or oxygen were mixed with it in sufficient quantity to prevent asphyxia, it would not produce anesthesia. Under pressure, however, these objections were done away with.

The author then gave a summary of M. Bert's experiments, and cited a number of instances in which French surgeons had performed capital operations under anesthesia by the method in question. The paper closed with the following conclusions:

1. Nitrous oxide, administered under pressure, and mixed with oxygen, produces within several seconds a profound insensibility.

2. Under these conditions, life may be indefinitely sustained without the least danger of asphyxia.

3. In augmenting or diminishing the pressure, the degree of anesthesia may be regulated at will, and with mathematical precision. Therefore, there is no danger of any of the accidents incurred through the use of ether or chloroform.

4. When inhalation of nitrous oxide and oxygen is stopped, the patient recovers consciousness in a few seconds and feels no consequent discomfort.

5. Nitrous oxide is merely dissolved in the plasma of the blood and escapes when inhalation ceases.

6. Its use causes no trouble to nutrition and no change in the chemical composition of the organs or cessation of their functions.

7. The action of compressed air upon the operator and his assistants need not be feared. Compressed air is very efficacious in the treatment of catarrh of the mucous membrane of the nose, the Eustachian tube, and the respiratory organs.

8. By reason of these facts, a mixture of nitrous oxide and oxygen is superior to ether or chloroform, whether we consider its profound anesthetic effect or its freedom from injurious results.

9. If the pressure of the air chamber is rightly and properly regulated it is absolutely impossible for the patient to run any risk from the anesthesia alone.

10. In all that concerns the application of nitrous oxide and oxygen to surgery, the scientific phase may be said to be exhausted, and this anesthetic agent should be henceforth used for operations of prolonged duration instead of ether and chloroform.

Dr. Howland then demonstrated the process: A small box was provided to serve as an air chamber, in which glass windows and a door were set and properly sealed. In this box a live chicken was placed. Into the chamber, by means of stopcocks and rubber tubes, pure nitrous oxide was first forced from a gas bag, producing insensibility in the chicken in the space of forty seconds. This was immediately followed by the mixture of nitrous oxide and oxygen, introduced from an iron reservoir, by means of which anesthesia was sustained for seven minutes at a pressure of four pounds to the square inch. The chicken was then removed from the chamber, feathers were plucked from it for five seconds subsequent to its removal without eliciting signs of pain, and within twelve seconds consciousness was fully restored. It was again placed in the box and pure nitrous oxide was introduced, with the result of causing death in fifty seconds. On removal and decapitation of the bird, its blood was found to be in a non-artificialized condition.
COLLEGE OF PHYSICIANS OF PHILADELPHIA.

(Concluded from page 213.)

To determine the average distance of the storm-center at the beginning of the pain attacks, sixty well-defined storms through ten consecutive months were taken, and it was thus found that the average distance was six hundred and eighty miles, ranging from two hundred to twelve hundred miles.

Storms from the Pacific are felt the farthest off very soon after crossing the Rocky Mountains. Those which move along the coast from the Gulf of Mexico are associated with neuralgia not quite so intense, and are not felt, as a rule, until within the average neuralgia distance.

If neuralgia begins on a low and rising barometer, the ridge of high pressure between this and the coming storm depression is narrow and invariably broken down within seventy-two hours, and more frequently within twenty-four or thirty-six hours; and during this rise, coincident with the pain, the difference between the wet and dry bulb thermometers, instead of increasing as is usual with this barometrical condition, sometimes actually diminishes, or increases for a few hours only, and then diminishes, showing increasing humidity.

When this pain and instrumental condition obtains, the coming storm depression will carry on its eastward side clouds and increasing moisture, and sometimes rain or snow, clear over the summit of the advancing high area pressure in front of it, holding an unusually high degree of relative humidity in the air on the high eastern slope of the high barometer area. These are the conditions when the pain attacks on the rising barometer. Its normal condition, however, is with a falling, but it may be a high barometer, rising temperature, and increasing relative humidity.*

If the pain be on during a day of intermitting rain, the pain takes an additional activity just before the increasing shower, and continues twenty to forty minutes; this will sometimes happen four or five times in twelve hours. Each little increment of pain seems to bear about the same relation to the showers as the main attack bears to the storm.

For the hourly relations of pain, see curve (Fig. 5), which shows the number of times the pain began on each hour of the day. The time of record extends over a period of more than eleven years, commencing September, 1871, and is continuous since October, 1874.

It has always been observed that eating a meal when the pain is on intensifies it, and it is believed that it often hastes the attack. We should then expect to find some rise in the curve after each meal. This we do find at 9 A.M., which can not be accounted for otherwise than that, by eating at 8 A.M., some of the neuralgia, which really belongs to ten o'clock, has been prematurely developed and so changed to nine o'clock. Again, after the one o'clock meal there is a decided rise in the number, some of which, at least, should be chargeable to the meal. It is also worthy of note that there is an ebb-tide in pain just preceding the meals; not so marked before breakfast, partly, no doubt, because it is with me a little less regular than other meals, and partly because storms coming within neuralgia range during the early and middle sleeping hours would not ordinarily arouse their victim, but would strike in the morning as the sleep became less profound.

This, doubtless, is the cause of the rapid rise in the curve between 5 and 6 A.M.

In support of this statement of the respect which a storm may have for its neuralgia subject, it may be added that, if the pain is on when the patient falls asleep, and he is aroused or awakens during the night, he will find himself free from pain; but if he should move about, or stay awake fifteen or twenty minutes, the pain is renewed, unless, in the mean time, the neuralgia time has expired.‡ At 11 P.M. the average number of attacks is not one a year, and from this time until 6 A.M. there is great immunity from eneets of pain.

With regard to the prominent and remarkable feature of the curve on the 11 A.M. ordinate, it can not be positively stated why the pain has shown this great partiality; but there are some reasons which may be of interest to state. We have found that the years of high mean annual pressure gave high pain readings. We have also found that neuralgia, in its relation to storms, was not adverse to a high barometer, but usually attacked on a falling barometer with rising temperature or increasing humidity.

The diurnal oscillation of the barometer is indicated by the elliptical curve in Fig. 5, which has for its ordinates the distances from the curve to the dial circle, and for its abscissae the hours of the day. The difference between the maximum and minimum pressure is 09945 of an inch. The minimum occurs about 4 P.M., and the maximum between 9 and 10 A.M., and begins its decided fall between 10 and 11. This brings the pain, then, in its relation to the diurnal change of the barometer, to a position analogous to what we found it in its relationship

* See same case in "American Journal of the Medical Sciences" for April, 1877, p. 21.
‡ This is true in regard to most pain, and may be within the experience of many a.o.c. we fall asleep suffering, but awake without pain, even if the cause of pain remains. A brief period of being awake seems to be needed, in order that the cause become active. Sleep is a true anaesthetic.—S. W. M.
to barometric movements accompanying storms—that is, high barometer, and on its fall preceding the storm, with increasing humidity and temperature. For the eight hours, from 9 a.m. till 4 p.m., during the daily fall of pressure, there are 610 onsets against 546 for the remainder of the day, or 16 hours, the maximum amount of vapor in the air from 2 until 6 p.m., increasing from before sunrise till just before sunset. We have, then, for the greatest daily neuralgic period a corresponding falling barometer, increasing vapor and temperature, with the analogous condition complete.

In regard to the 11 a.m. period, there are some other points of interest.

By a reference to the diurnal changes in the magnetic curves, we find, in the declination curve, two maxima and two minima daily. The principal maximum occurs at 8 a.m., and the principal minimum at 2 p.m. From this minimum, in its progressive movement, there is a slight undulation in the curve about 10 p.m., giving rise to a subordinate maximum with another minimum following two hours later near the mean of the curve; from this we reach the principal maximum at 8 a.m.

In the inclination curve we have also two maxima and two minima. The leading and principal feature of this curve is its morning maximum, which occurs between 10 and 12 a.m., probably 10.45 or 11 a.m. A subordinate maximum about 10 or 11 p.m. There is a minimum between 5 and 6 a.m., and another about 5 p.m.

Each of these maxima has a corresponding minimum in the horizontal force. So also the minima in inclination correspond in like manner to maxima in horizontal force. Owing to the great and precipitate change in declination between 8 a.m. and 2 p.m., with the pronounced occurrences in inclination and horizontal force at or close to 11 a.m., may we not with some reason suspect these as active agencies in constructing the 11 a.m. neuralgic period?

The two o'clock period is one connected with the highest temperature and the maximum wind force of the day. It is believed that hours of maximum and minimum rain-fall have some influence on this curve. The British government* has published some observations which, although not conclusive, seem to show that there are two daily maximum rain-falls, one at 1 p.m., and one at 5 a.m.; also two minimum periods, near noon and midnight. It is believed, further, from sensible impressions and limited observations, that the solar and the earth's radiation have an influence on the daily character of the neuralgia, and, if fully studied, would assist in interpreting some features of the curve not fully understood. With complete record of local meteorology, including radiation, there seems but little doubt that all the details of the diurnal curve could be demonstrated. There is one additional fact in connection with the onsets of pain which seems curious, and that is the period of drowsiness and sleepiness which precedes the attacks from one to five hours. This rule is not invariable, but is general.

For the seven years from November 7, 1875, to November 17, 1882, there have been nine neuralgic attacks of great and unusual power. These were characterized by pain in nerves not usually attacked. The ordinary neuralgia is confined to the position indicated in Fig. 6, and is of the burning and boring kind, with twitchings of nerves in the stamp, while in the extraordinary attacks, in addition to the pains as above named, we have the intense stabbing variety, with a much higher degree of the convulsive tendency. Accompanying each of these attacks, except the last, we have the pain period dominated by more than one storm in six out of the nine attacks, and in every case the low barometric depression was of unusual and enormous extent. The attack of November 7, 1875, began at 7 p.m. and lasted until 2 p.m. on the 8th, and was undoubtedly mainly under the influence of Storm No. IX (as charted by the Signal Bureau), while passing from Savannah to a position off Cape May.

The depression of this storm "became more extended as it advanced, with increasing velocity, the region of precipitation including the entire Southern and Middle States." By 7 p.m., closely following this attack, was an attack of the regular neuralgia, which lasted twenty-seven hours, to meet the requirements of Storm VI; and this is a general rule, that these unusual attacks are followed by the regular neuralgia.

The attack of September 29 and 30, 1876, was under the influence of Storms IX and X of that month. The weather report of the Signal Bureau says: "The map of the 29th, 4.35 p.m., shows that at that time a very large area of low pressure must have existed in British America on the south and east of James's Bay, the southern end of which extended southward until, on the morning of the 30th, the barometer was below thirty inches everywhere east of Lake Superior. The winds of Georgia and Indiana during this time were from east to southeast.

The attack of April 3, 1877, belongs to Signal Bureau Storms Nos. II and III. "An extensive area of cool northeasterly winds prevailed throughout the Gulf States, Ohio Valley, and Lower Lakes." In the Middle Atlantic States northerly winds moving to east, with increasing cirrus and cirro-stratus cloudiness. The general depression extended over a large area. The attack of August 3, 1877, belongs to storm marked II on monthly report. "There was a marked fall of the barometer in the Southern Atlantic States on the 2d, which district was then, in all probability, in the N. W. quadrant of an extensive depression." "N. E. winds prevailed from New York to Florida." The neuralgia attacked at 11 a.m., and at this time in

the direction of the storm S. E. there were increasing cirrus and cirro-stratus, with bunches of cumulonimbus lower. This storm "united with No. I over the St. Lawrence. Later in the day thunder-storms in northwest to northeast." The attack of May 31, 1879, corresponds to the extensive storm of No. XV of Signal Bureau Report for the month.

The attack of October 16th corresponds to Storms IV and V; the former, coming up the Mississippi Valley, unites with the latter, from the North Pacific, in Lake Michigan.

The attack of April 10, 1881, is related to Storm III, including Storms II and IV as described by the Signal Bureau Report.

It was observed on this occasion, as is frequently the case with this variety of pain, as also in the ordinary kind, that there was a cloudless sky with a delicate milky sheen in the atmosphere, more marked around the horizon. This milky veil becomes more opaque, and the first pronounced cloudlessness will be small patches of cumulus, at lower elevation than this hazy appearance. These are storm indications, and favorable for the production of pain. This was the stabbing variety, as in each case here described, added to the other varieties, and was active between the heel and left side of foot. (See diagram.)

The attack of February 11, 1882, corresponds to Storm VI as marked in report of Signal Bureau. At the time the attack began, the center of the storm was six hundred miles westward. This was of wide lateral range, and is the only one charted for the month as coming from the Pacific coast.

For an attack of November 17, 1882, Professor Carymail, Superintendent of the Toronto Observatory, reports more than ordinary declination and force disturbances from the 10th, including the 16th, when "they evidently showed signs of a coming storm." The magnetic storm set in at 5 a.m. on the 17th, and continued with great and intermitting force all day and night, and did not quiet down till midnight of the 18th. The report says, referring to the evening of the 17th, "that the force (horizontal and vertical) instruments which in the early part of the storm showed a general decrease, now showed an increase, and between 7 p.m. and midnight the lights several times traveled to both ends of the paper, the hislar going off a number of times." The extremes of declination were reached easterly at 6.25 p.m. and westerly at 9 p.m. On the 19th the magnets were disturbed, the disturbances being greatest between 11 p.m. of the 19th and 4 a.m. of the 20th. Many of the force movements were swift and rapid, the last movement of importance occurring at 9.20 a.m. on the 20th. Brilliant auroras reported on the 17th.

This storm was unusually severe in England, with brilliant aurora on the 17th. The disturbances here probably did not differ materially from those reported from the Toronto Observatory.

There was from the 10th inst. great unrest in all the nerves of the foot, such as feelings of twitching and slight burning, and at no time did the agitation touch the zero line of no pain. At 2 p.m. of the 17th the intense stabbing pains set in and reached the maximum power from 4 to 7 p.m. They continued, however, with great force until 5 a.m. on the 18th, and intermitting and less strong fits of torment were felt till evening; then a period of rest occurred until 9 a.m. of the 19th, when a severe attack of the regular neuralgia set in, with more or less burning and twitching pains throughout the foot, which lasted more than thirty-one hours, and finally went off on the evening of the 20th. The intense neuralgia of the 17th seems connected with the magnetic storm of the 17th, for there was no storm of barometric depression charted by the Signal Bureau within neuralgic range for this date. The last storm preceding this time was Storm No. 11, which started from the Pacific on the 8th, and for which there was a regular neuralgia on the 9th and 10th. The next storm was No. III, which originated in Texas on the 18th, and the attack of pain of the 19th and 20th was for this storm aggravated by the magnetic condition of these dates. It is firmly believed that neuralgia accompanies intense auroral periods, but, owing to their rare occurrence, it can not be said that the proof is conclusive. The conjunction of the two seems too frequent for mere coincidence.

In regard to treatment, etc., I can say but little. There has been no treatment in a medical way of late. I have had good health; take a great deal of exercise, but in a rather irregular way; my appetite is always good, and I sleep well, except when the disturbance of neuralgia interferes. For the year 1878, in which occurred the greatest diminution of pain for any year, there was the greatest physical weight, reaching one hundred and ninety pounds. Physical exercise, nutritious food (have found milk most fattening of all), and light, agreeable occupation, are, I found, the best regimen for this neuralgic subject.

NEW YORK MEDICAL AND SURGICAL SOCIETY.

A stated meeting was held March 10, 1883, Dr. T. F. Cock chairman for the evening.

UNUSUAL EFFECTS OF ANESTHETICS.—Dr. F. N. Otis related a case in which, after an operation for phthisis upon a child two years of age, he had removed the stitches while the child was slightly under the influence of ether. Shortly afterward he looked at the child, and found it in good condition; but as he was about to drive away, Dr. L. B. Bangs, who had seen the patient last, remarked that he looked a little pale, and he returned to the room to make sure that everything was right. Very much to his surprise, he found the child in a state of collapse—pale, pulseless, and not breathing. He immediately practiced artificial respiration. The child was soon completely restored. Dr. Otis remarked that this was the only case in which he had observed any tendency to collapse so long after the administration of the anesthetic.

Dr. Fordyce Barker said that in Dr. Otis's case the child was not fully under the influence of the ether. The nervous and vascular systems were in a high state of excitment, and afterward there probably came a reaction, a condition of partial collapse. He asked whether any case had been reported in which a child under ten years of age had died under the influence of chloroform.

Dr. A. C. Post said that a child was once brought to the late Dr. Buck for some affection which rendered it necessary to employ an anesthetic on several occasions, and the father preferred that chloroform should be administered. Dr. Buck, however, objected, on the ground that it was more dangerous than ether. On one occasion, when Dr. Buck could not attend to the case, the child was taken to another physician, who had no objections to the use of chloroform. It was administered, and the child died under its influence.

Dr. Francis Delafield remarked that a number of cases of death from chloroform in children under ten years of age had occurred in New York, one under his own observation. Dr. Otis asked whether his case had been reported in which death from ether had occurred in a child.

Dr. Delafield believed none had been reported except where strangulation took place during vomiting. With regard to Dr. Otis's case, it was doubtful whether the state of partial collapse could be attributed to the direct influence of the ether.

We all knew with what comparative ease children under three and four years of age were sometimes seized with a temporary feebleness of the heart's action, with apparent collapse. Sometimes it could be attributed to a slight attack of indigestion; sometimes there was no apparent cause, yet the symptoms were
exceedingly alarming, and the collapse continued for several hours. Only last week he had seen such a case in a child two years old, that for an hour looked as if it would surely die. There was no apparent cause, and the child had been in perfect health. The next day it was as well as ever, and had shown no symptom of sickness since. He thought that the collapse in Dr. Otis's case was probably due rather to the vomiting and the struggling than to the direct effects of the drug itself.

Dr. Post remarked that he had seen but two cases in which a fatal result had attended the administration of ether. One occurred in the New York and the other in St. Luke's Hospital. The operations were done for tumors of the neck which compressed the larynx and the trachea, and difficult breathing was superadded to the influence of the ether. The patients died on the operating table.

Dr. B. W. McCready thought that when a person, particularly a child, was about to undergo an operation, the heart's action, influenced by fear, was usually comparably feeble. If chloroform were used, not being disagreeable to the patient, it produced no reaction, took effect rapidly, and was likewise a depressor of the heart's action. Ether, on the other hand, acted slowly, was disagreeable, and always caused the patient to struggle more or less, and he thought the heart, perhaps, had an opportunity to regain its power of action before the depression attending complete anaesthesia came on.

Dr. C. R. Aengew thought it our duty, before administering anaesthetics to the extent of full anaesthesia, to ascertain the state of the kidneys, so far as possible, and to make sure that the patient was not suffering from any condition contraindicating the anaesthetic.

Dr. Post alluded to the advantage of "primary anaesthesia" for slight operations.

Dr. R. F. Wein remarked that, with regard to the kidney symptoms which sometimes developed after anaesthetization, it was often difficult to say whether they were due to the direct influence of the drug or to surgical fever.

Dr. Otis remarked that dropping of the uplifted hand was not a sure sign of the presence of the stage of anaesthesia referred to; he had recently seen the arm remain rigid in an upper position some time after the inhalation had ceased.

Chancre of the Mouth contracted during Abnormal Cotes.—The case was observed in Dr. Wein's service in Bellevue Hospital in November. A boy nine years of age was admitted for compound fracture of the leg. About a week afterward a general eruption broke out, which was recognized as syphilitic. There was an enlarged gland just below the angle of the jaw on the left side, and further examination disclosed a chancre of the corresponding tonsil. The boy said he had been induced by a man to take part in the abnormal cotes that gave rise to the sore about six weeks before the eruption had appeared. Dr. Robert W. Taylor had confirmed the diagnosis.

A stated meeting was held March 24, 1889, Dr. T. F. Cock chairman for the evening.

Traumatic Deviation of the Septum Nasi.—Dr. A. C. Post mentioned the case of a girl, seven years of age, who, about two years ago, fell and injured the nose, causing a deviation of the septum so far to the left as materially to interfere with breathing through the left nasal passage, and giving a nasal twang to the voice. Instead of trying to make direct excision of the displaced portion, according to the ordinary, and, he believed, rather difficult method, he made a transverse incision through the columna nasi, then separated the divided portions, turning the one forward and the other backward, thus exposing the lower part of the septum, and enabling him to circumcise the displaced septum with the curved scissors and remove it.

Hemorrhage following Trephining of the Mastoid.—Dr. H. D. Noyes, by invitation, narrated a case as follows: The patient, a girl, sixteen years of age, had been under his care for chronic otitis media of both sides during the past eight years. On Sunday last severe symptoms developed, suggestive of meningitis. There was slight vomiting, a chill, then great elevation of temperature and frequency of the pulse, mild delirium, and severe headache—symptoms which continued for four days. When he saw the patient there was unmistakable deep-seated tenderness in the region of the squamous portion of the temporal bone on one side. Feeling that the symptoms were not likely to be relieved by the incision made over the mastoid, he determined to trephine just on a level with and half an inch back of the external auditory canal. After penetrating to a slight depth with the sharp pointed drill, a square one was substituted. At a depth of a quarter or three eighths of an inch this suddenly dropped into a cavity, and he felt the impact of the instrument against the opposite bony wall distinctly. The drill was withdrawn and an attempt was made to ream out the hole by which it had entered slightly, to allow free exit of any fluid that might be present, but there suddenly occurred such a free flow of venous blood that, for a moment, he feared the lateral sinus might have been opened. But, in the light of the anatomical structure of the parts, this appeared impossible. A cotton tampon was introduced, the hemorrhage ceased, and the severe symptoms from which the patient was suffering had since disappeared to a considerable extent. This was the first case in his experience in which trephining the mastoid had been attended by severe hemorrhage.

Dr. Post remarked that the veins in the diploë of the bones of the skull were sometimes quite large, and that possibly Dr. Noyes had accidentally struck one of these in the mastoid.

Dr. Notes remarked that it was well known that a large vein passed through the mastoid, but its locality was uncertain.

Abscess of the Cerebellum; Sudden Death.—Dr. G. G. Wheelock related the case of a woman at the Nursery and Child's Hospital who, about three weeks after delivery, was attacked with a slight pelvic inflammation, and was removed to the annex. The temperature was only slightly elevated, and before that there had been no symptoms whatever. She had been deaf for many years, the result of chronic otitis media on both sides. One night recently a slight discharge took place from one ear, and the patient seemed to be a little stupid. Without any warning, while being served by the nurse to a glass of water, she suddenly threw her arms up and appeared to be dying. Attempts were made at resuscitation, but within four minutes all signs of life had disappeared. At the autopsy the next day an abscess an inch and a half by an inch in diameter was found to occupy the right lobe of the cerebellum at a point just posterior to the petrous portion of the temporal bone, which was supposed to have caused death suddenly by pressure upon the respiratory center. There was also adhesion of the membranes to the bone at this point, and, with the slightest force, a thin shell of the bone was broken through and a cavity disclosed which was found to contain cheesy material. The peculiarity of the case consisted in the absence of brain symptoms.

Dr. Notes remarked that the number of cases in which the disease produced no cerebral symptoms was not small.

Dr. Post thought it was not uncommon for physicians to tell the parents of children who had otorrhoea that they would outgrow it, and that they need not pay any attention to it. He believed, however, that it was a very serious mistake to let such cases go untreated.

Dr. Notes added that to differentiate between the symptoms of meningitis and those which were due to inflammation con-
fined to the region of the mastoid was sometimes quite difficult. In the case he had related he had been actuated, by prudential reasons, and a previous knowledge of the case, not to wait longer, but to perforate the mastoid so early as the fourth day. He had also made an ophthalmoscopic examination, to see if there existed what had been found in a number of this class of cases at the early stage, namely, acute inflammation of the optic nerve on the side corresponding to the ear lesion. Optic neuritis, however, did not exist, but one portion of the nerve was found to be intensely vascular, while the remainder was normal, and this fact, taken with the others mentioned, he believed justified the operation.

A stated meeting was held April 14, 1883, Dr. William N. Blakeyman chairman for the evening.

Probable Injury of the Heart Due to a Fall.—Dr. A. C. Post said that a young man presented himself at his clinic today, complaining of certain symptoms caused by a fall sustained a week ago, while staggering under a load of lumber. He was afterward able to walk to a conveyance, but was very feeble and suffered distress. Upon examination, no evidence of contusion or fracture could be discovered, but the patient complained greatly of pain, distress, and tenderness over the region of the heart, particularly when percussion was made. The pulse was very rapid, feeble, diarrheic, and irregular, and the heart’s action was jerky, feeble, and tumultuous, but no abnormal sounds or percussion outlines were discovered. Possibly there had been rupture of some of the endocardial tendinous cords.

Epidemic Conjunctivitis.—Dr. C. R. Apgar said that he had seen within the past six weeks an unusual number of cases of conjunctivitis; a larger number than at any period since the agitation occurred in this city with regard to dirty streets more than a year ago, at which time the occurrence of a peculiar type of conjunctivitis was supposed by some to have been due to the great amount of pulverized filth which was being wafted by the winds. The type of conjunctivitis which he had lately seen resembled very closely that which existed at that time, yet we had not, owing to moisture in the atmosphere up to the present time this spring, been much afflicted with dust. The disease was peculiar in the fact that there was intense redness, starting in the retro-tarsal fold, extending to the conjunctiva of the lids, and thence to that of the eyeballs, while there was very little or no mucous secretion. It was not confined to the city; cases were reported from other portions of the State. A similar epidemic existed in 1827 or 1828. That the epidemic of last year was not caused, in the first place, by the filth of the streets, was evident from the fact that many cases occurred in the country, both in New York and in New Jersey, particularly in the town of Woodbridge, in the latter State. These facts should make us cautious in attempting to assign as a definite cause for endemic diseases some condition which might at the time happen to annoy us. He asked Dr. H. D. Noyes if he had observed an unusual number of cases of acute conjunctivitis during the past six weeks.

Dr. Noyes replied that he had been less struck with the prevalence of conjunctivitis than with catarrhal conditions of the ear of a troublesome character.

The Relation of Laceration of the Cervix Uteri to Epithelioma.—Dr. Robert Watts said that the opinion frequently expressed by Dr. Emnet with regard to the etiological relation between laceration of the cervix of the uterus and epithelioma in that situation was well known. The following cases perhaps had some bearing upon that point. Within the past two months a woman entered the Roosevelt Hospital who had been losing blood constantly for four weeks previously. On examination, a pretty extensive laceration of the cervix was discovered, and springing up from the anterior lip was a cauliflower-like growth about as large as half an English walnut. Slight handling caused haemorrhage. It was curedt, and the surface from which it sprung was deeply canneterized. The wound had since healed perfectly, and the patient was now in condition to have the laceration repaired. The specimen had been examined by Dr. Delafeld, who stated that it was just on the border-line between simple papilloma and epithelial degeneration, and that, undoubtedly, had it been allowed to remain any length of time, it would have assumed all the characteristics of a real cancerous growth. About two years ago Dr. Watts treated a case in the same manner, in which, although there was not a cauliflower-like growth from the cervix, the lining membrane was very vascular, and a specimen under the microscope presented the same appearances as in the present case. The patient had since had several attacks of profuse haemorrhage, but was otherwise in perfect health, and there had been no recurrence of the local disease.

Prolonged Intra-uterine Gestation.—Dr. T. F. Cook mentioned the case of a primipara who, after a single coitus, was delivered of a child on the 299th day. The case was well authenticated.

A stated meeting was held April 28, 1883, Dr. H. F. Walker chairman for the evening.

Erysipelas Migrans.—The Chairman was lately called to see a female child, two years and a half old, on account of a slight degree of fever. He was unable to account for this symptom until the following day, when the mother incidentally said that the child had a little difficulty and pain on urination. On examination, he then found the left labium majus considerably swollen, and the case appeared to be one of follicular vulvitis. The next day, however, it became evident that it was erysipelas. It gradually extended down the left thigh and up on the abdomen, and, clearing up on these parts, continued to extend down the left leg to the ankle, and spread to the right thigh, where it pursued a similar course as far down as the ankle, where convalescence set in. Some small abscesses formed upon the lower limbs. He had seen but one similar case before, which also occurred in a female child, and the erysipelatous inflammation extended upward upon the abdomen, around upon the buttock and back, but not down upon the legs. In the first case mentioned, the child had been previously healthy; there had been no injury.

Puerperal Fever; the Vaginal and Uterine Douche.—Dr. J. W. McLean mentioned a case of erysipelas in the newly born child, and puerperal septicemia in the mother, as follows: The patient was confined Friday a week ago with her fourth child. The former labors had not been difficult, although at the first the perineum was considerably torn. The last child was large, weighing very nearly twelve pounds, and was extracted, after some difficulty, with the forceps. A slight wound was made near the brow, from which erysipelas developed, and spread to a trifling extent upon the head and neck. The temperature did not rise above 101° F. No medication was employed. The nurse at first had passed back and forth from the sick mother to the child, and the disease had probably found its origin therefrom. On the third day, the temperature in the mean time having been normal, the mother complained of slight chilly sensations, but there was no marked chill. The temperature rose to about 102-5° F., and by evening was a degree higher. On the morning of the fourth day the temperature was 104° F., and at evening 106°. There was no pain over any part of the body. There was rapid distension of the intestines, such as was seen in septicemia involving the lymphatics, and a number of semi-liquid stools took place. When the temperature had risen to 106°, the
MISCELLANY.

Moreover, Bilin lor twenty-four fornix cases, necessary vagina, sorption and only washed it sorption believe ately tain ing born fall. the proved dead. after his. in Dr. Dr. Dr. McLean, head was practice days and proved him. of the matter proved, viz., that ascites, of the question the was, of the puerperal danger of the temperature was, of used in decantation. The proper amount to be injected in twenty-four hours is one hundred grammes [28 drachms], this corresponding to the quantity of bile secreted by the liver in the same time. The hundred grammes of tauro-cholate of sodium should be dissolved in one litre [2 1/2 pints] of water at the temperature of the body. Dr. Taylor submits that the form of treatment here proposed could not be less successful than the various plans which have been followed hitherto and with such eminently unsatisfactory results.

Veratrine as a Remedy for Tremor.—M. Féris, of Brest ["Progrés médical," July 14, 1883], has come to the conclusion that veratrine will control the tremor of alcoholism, of various nervous affections, and of the state following pyrexia. It is to be given in half-milligramme pills, four of which should be taken daily. The action is apparent almost immediately after the first dose are taken. The tremor is thus checked for a sufficient length of time, its incidence remains for a long period after the use of the drug is suspended. This persistence has been observed for almost two months. The treatment should be continued at least ten days in order to produce permanent results.

M. Dubois ("Gazette hebdomadaire de médecine et de chirurgie," July 27, 1883), in reviewing the conclusions of M. Féris, observes that most of the active principles, administered during the state of alcoholic intoxication, from the time the tremor is of the greatest intensity (the patient having abruptly stopped the alcohol), will act like veratrine to check the tremor.

Amorphous Quassia.—M. Pierre Vigier ("Gazette hebdomadaire de médecine et de chirurgie," July 27, 1883) calls attention to the amorphous quassia which the market now affords. He brieves it to be preferable to erystialized quassia, while it is also less expensive. Amorphous quassia may be conveniently administered in pill form, thus: B Quassia amorph., 2 grammes; ephedrins, 9 1/2 grammes. M., div. in pil. no. C. Sig. Two to three each day.

Substrate of Bismuth as a Remedy for Puerperal Fever.—M. Vieusse, Surgeon-Major, military hospital of Oran ("Gazette hebdomadaire de médecine et de chirurgie," July 27, 1883), advocates the use of substrate of bismuth locally in the treatment of
MISCELLANY:

In an experience of fourteen years he has met with but one case that was not fully amenable to this treatment. It is adapted to all the forms, or rather degrees of severity in which this comparatively trivial, but nevertheless annoying and disgusting afflication is encountered. Five to seven dracontes of the powder should be rubbed daily into the feet, not neglecting the surface between the toes. From five to fifteen days usually suffice to effect a permanent cure. There is no reason to fear that the checking of the perspiration will be followed by the establishment of some compensatory trouble, as has been alleged by certain writers. M. Vienue attributes to the blisthem a purely local action. Under the action of the sulphuric acid of the perspiration "the blisthem loses part of its base, and, becoming acid, it exercises an astringent and slightly caustic action upon the skin." In consequence, the epidermis becomes stronger and firmer, and separates with less facility from the subjacent derma. The better tone thus imparted to the skin tends to lessen the amount of blood circulating therein, and this, in turn, diminishes the secretion of the sudoriparous glands and the sebaceous follicles. At the same time, the derma, protected by a thicker and more resistant covering, does not become demolished, and, therefore, the pain due to such demudation ceases.

M. Vienue cites one case in which the suppression of the sweating was but temporary. However, even in this case the offensive odor and the pain were permanently stopped.

Cold Baths in Typhoid Fever.—M. Dumontpallier ("Progrés médical," August 4, 1888) expresses his belief that cold baths employed according to the method of Brand are of the greatest service in typhoid fever. His observations indicate that the systematic employment of this method not only does not cause visceral congestion, but relieves such congestion if it be present. Intestinal hemorrhage is not a contraindication to the use of the cold baths.

Iron and Arsenic in Anaemia and Chlorosis.—Dr. Frederick Willcocks, Assistant Physician to Charing Cross Hospital, London, in concluding an interesting article on some points in the pathology of anaemia, and on the action of iron and arsenic, remarks that, in severe anaemia, either the power of corpuscle formation is almost entirely abolished, or the young corpuscles, if formed, have little or no power to absorb hemoglobin, and, consequently, do not reach their full development. The comparatively large size which the hematoblasts attain without the absorption of any appreciable quantity of coloring matter, would go far to show that the embryonic corpuscles are more or less abortive. Iron in these cases is useless beyond a certain point, the existing corpuscles being already overcharged with hemoglobin. These facts forcibly bear out the hypothesis as to the probable hematinic action of iron—viz., that it possesses no power of directly stimulating the formation of new corpuscles by any influence on the cytoplastic organs, but that it improves the hemoglobin richness of already existing corpuscles which are added to the blood by the normal processes, and, consequently, by improving their physiological value and vitality it indirectly increases their number. Therefore, where the natural power of sangungilation is greatly reduced, or almost abolished, iron has little or no beneficial effect, since either very few new forms are produced, or, even if they are added to the blood, they have little or no capacity to absorb hemoglobin and to develop into adult corpuscles. Chlorosis is in striking contrast to the most severe forms of anaemia, and results mainly from its lessened blood loss and in its response to iron treatment. In chlorosis the supply of young, feebly colored corpuscles is abundant, and the number of red discs to the cubic millimetre may fall in many cases but slightly below normal. The average hemoglobin richness of the corpuscle is greatly reduced, and the curative effect of iron is very rapid. A low average hemoglobin value in the corpuscle is not, however, peculiar to chlorosis, but is present in the large majority of anaemic cases from all causes. It indicates that feebly colored or young elements are being continually added to the blood, or, in other words, that the normal process of globule regeneration is active, the numerical rise preceding the rise in the physiological value of the elements. It is in these cases that iron is indicated. Arsenic was given in two cases of chlorosis, but it had no influence either in preventing relapse on the cessation of iron, or in improving the numerical or value of the red corpuscles. On the other hand, in the most intense forms of anaemia, with great diminution in the number of the corpuscles and a high relative hemoglobin value, iron is practically useless, or even harmful, while arsenic may produce a considerable rise in the number of the corpuscles, as well as great improvement in the general symptoms.

Removal of a "Cavernous Anoma" of the Tongue.—In the August number of the "Practitioner" Mr. Henry W. Freeman relates a case of this sort, and adds the following remarks:

"Mr. Morrant Baker's method of slitting the tongue through the middle from apex to base with a straight probe-pointed bistoury and cutting through half the base with the wire-robe écasser when the whole of one half of the organ is involved, answers excellently well; but, seeing that more than an inch of the front of the tongue was here free from disease, we determined upon a modified procedure, the result being that the balance of the tongue was well maintained by preserving its tip with the attachments to the floor of the mouth, and articulation and swallowing were not materially interfered with.

"The lingual artery normally runs an oblique course from its origin to its termination. It is very tortuous, and has very few anastomoses, and does not enter the inferior surface of the tongue at its extreme base; and I venture to presume that—with the cheek well retracted or, if needs be you require more room, dividing the cheek horizontally from the angle of the mouth backward—you can, with a curved needle, transfuse one half of the tongue in front of the foramen cecum, and with the wire rope cut through transversely without dividing the main trunk of the lingual. The dorsal branch of this artery seems to supply the root and the circumvallate papilum. It is well to remark here how fialle the tongue-structure seems to be when cut through at a right angle to its long axis, the rope passing through when the slightest tightening was made by the écasser screw. It cuts through as easily as liver.

"In order to secure a good operation, the wire rope requires to be made of the softest and most pliable material. Sir James Paget has recommended the use of strong whip-cord, and it is preferable to the stiff, unmanageable rope usually supplied with the écasser. We secured from Krohne and Sesemann for this case a steel rope, finely manufactured with material of the most malleable description. It was as pliable as whip-cord, and I have recently used it with Goebb's cannula in ligaturing an intramural tumor, and found it quite as manageable.

"In administering anaesthetics in excisions of the tongue it seems all-important that the anaesthesia should not be profound. I hold that partial insensibility is only admissible. I have seen more than one fatal case during removal of the tongue, the patient being profoundly insensible. If there be much or little bleeding, mop as much as you may, some blood trickles backward and little pools accumulate in the glossopharyngeal pouches and flow over into the larynx, and the epiglottis, being held erect by the drawing forward of the tongue, can not divert its course. The patient would cough up the blood if only partially under the anaesthetic, and this course was rigidly carried out in the present case."

The Indian Origin of the Cholera in Egypt.—Mr. Robert Lawson, Inspector-General of Hospitals, of the British army, has written a letter to the editor of the "Medical Times and Gazette," of London, in which he uses an expression (which we italicise) going to show that in his opinion the disease now raging in Egypt is genuine Asiatic cholera. Mr. Lawson says:

"While thanking you for the readiness with which you inserted my letter of July 26th in the "Medical Times and Gazette," I deem it necessary to offer the following remarks on one point in the observations you appended to it. You refer me to page 101 of the Report on the Cholera Epidemic in the United States in 1873, to show that the disease at New Orleans was not of the type common in India, or which now rages in Egypt, but resembled the severe diarrhoea which prevails everywhere in hot weather among insanitary surroundings; and from this you consider that not only my conclusions, but my premises, fall to the ground. Now, the disease commenced in February, and up to
the beginning of April, when the weather could not be called hot, there had been 'thirty-one cases, of which two (2) were recoveries' (Report, page 97). This does not indicate a slight form of disease, to begin with, whatever it became subsequently as the usual season for diarrhoea came on.

"Again, as to the relation in which the first cases stood to the subsequent spread of the disease, and as to its nature, I refer you to page 1 of the Report, where it is stated that in 1873 cholera prevailed throughout the valley of the Mississippi, commencing at New Orleans, from which it extended northward, and became epidemic at all points attacked. The vast majority of the medical men who were engaged in combating the disease were unanimous in pronouncing it Asiatic cholera. A second class—respectable, both numerically and intellectually—recognized the disease to have been cholera in a fatal form, but of American origin; whilst others regarded it as a pernicious bilious or malarial form of fever. The general consensus of opinion, then, was that the disease was a fatal form of cholera—a conclusion which few who have perused the Report carefully will be inclined to doubt.

"These facts place my premises regarding the outbreak at New Orleans beyond question, and I must leave your readers to form their own opinions as to whether my mode of treating these premises, or that you seem to recommend, is most in harmony with the modern spirit of research, or most likely to enable them to clear away the obscurity which now envelopes the mode of origin and of spread of cholera."

MOLLERSENM. CONTAGIONEM. GIGANTESCUM.—Under this name, says the Medical Times and Gazette," Dr. S. Laache, of the Anatomec-Pathological Institute of Christiania, describes, in a recent number of the "Nordisk medicinlist Arki," a tumor extripated from the neck of a female aged fifty-six. This tumor, which had lasted for thirty years, but had increased considerably for the last four years, was of the size of the fist, with nodulations or unequal protuberances on the surface; it was covered at its base with normal skin, sending tumefied ramifications over the whole tumor, which were transformed at last into a delicate membrane, half pellucida and half granular, covering the whole mass except at the summit, where there was a flat crateriform depression. Under this incomplete covering there was the mass of the tumor, which, as it were, undulated against the surface. The cut surface, equally composed of nuclei of unequal size, separated by septa of cellular tissue, presented a granular aspect, but without the knife being covered with adipose matters. Examined by the microscope, the lobules contained, in the circumference, cells evidently resembling epithelium, while in the center was a considerable number of corporules with an adipose or way interspersed strongly resembling amyloid tissue. In all other respects they resembled the corporules of molluscum, with which the author compared them. In his remarks on the case, Dr. Laache discusses the differential diagnosis between molluscum and epitheloma or cancrum, to which last the tumor was at first referred. From cancerous, however, the molluscum in question was distinguished by its definite form and its tendency to grow outward, besides by its being covered entirely by a kind of delicate skin without any apparent ulceration. It was, however, the presence of corporules of molluscum in considerable number which determined the diagnosis. The author admits, however, that, as regards prognosis, the tumor may not be regarded as being so benign as ordinary molluscum, and he therefore thinks it ought to be considered as a transitional form between the malignant epithelial tumour and the benign one. He observes that there was no relapse at the end of more than six months. In conclusion, Dr. Laache considers the presence of nuclei in several of the shining corporules as a proof in favor of the opinion that the corporules of molluscum are the results of a peculiar degeneration of pre-existent epidermic cells.

THE COMMUNICABILITY OF SYPHILIS TO ANIMALS.—A recent number of the "Wiener medizinische Wochenblatt," quoted in the "Medical Times and Gazette," contains two papers on this subject. One is by Köhner, and the other by Neumann. Both investigators arrive at the conclusion that true syphilis can not be transmitted to animals. Köhner obtained positive results with inoculations performed with scrapings from a soft chancre on rabbits. Frequent inoculations with pus from simple and serofloccous buboes never gave any result. Köhner concludes that there is a specific contagium in the pus from a soft sore. Something more is necessary than mere contact if successful inoculations with the pus from a soft chancre are to be made. There must be a wound; and the deeper this goes, the greater the certainty of a successful result. Experiments were chiefly performed on the conjunctival sac of rabbits. Klebs, Aug. 1883, found bacillus in syphilitic new growths, but Köhner has to confess that, in spite of trials with all the new methods of staining, he has been unable to find the bacilli in excised papules of the skin and inflations where the surface was quite unbroken.

The American Public Health Association will hold its eleventh annual meeting in Detroit, beginning November 16th. The Pennsylvania State Veterinary Association was lately organized in Philadelphia.

Queen's Dictionary of Medicine, published by Messrs. Longmans & Co., must take rank among the most remarkable successes in modern medical literature. The sale has already reached seven thousand in this country, and a large issue has been sold in America—British Med. Jour.

EULLOPHIA GIGANILE IN THE TREATMENT OF CULIERIA.—In a recent report to the Surgeon-General of the Navy, Passed Assistant Surgeon F. B. Stephenson states that the Eullophilia gigantea, an orchid found in the United States of Colombia, is the best remedy known for chyliasis.

ARMY INTELLIGENCE.—Official List of Changes of Officers serving in the Medical Department of the United States Army from August 18, 1883, to August 25, 1883.—Menheto, J. V. D., Major and Surgeon. Relieved from duty at Fort Hayes, Kansas, and assigned to duty at Fort Leavenworth, Kansas. Par. 2, S. O. 109, Department of the Missouri, August 18, 1883. —— Williams, John W., Major and Surgeon. Granted leave of absence for one month, on surgeon's certificate of disability. Par. 1, S. O. 109, Department of the Columbia, August 8, 1883. —— Barton, John H., Captain and Assistant Surgeon. Assigned to temporary duty at Vancouver Barracks, Washington Territory. Par. 2, S. O. 109, Department of the Columbia, August 8, 1883. —— Finley, J. A., Captain and Assistant Surgeon. Relieved from duty at Port Concho, Texas, and assigned to duty at Port Stockton, Texas, as post surgeon. Par. 1, S. O. 101, Department of Texas, August 16, 1883. —— Kimball, James P., Captain and Assistant Surgeon. Relieved from duty in Department of the Platte and to proceed to New York City and report in person to the President of the Army Medical Examining Board for duty as a member of that board, vice Surgeon Clemens, relieved. Par. 1, S. O. 198, A. G. O., August 22, 1883. —— Clements, Bennett A., Major and Surgeon. Relieved from duty with the Army Medical Examining Board, New York City, N. Y. Par. 11, S. O. 193, A. G. O., August 22, 1883. NAVY INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during the week ending August 25, 1883.—Assistant Surgeon A. A. Austin, ordered to Naval Hospital, New York. —— Assistant Surgeon T. C. Craig, detached from Naval Hospital, New York, and ordered to the United States steamer Minnesota. —— Passed Assistant Surgeon M. H. Crawford, detached from the United States steamer Pinta, and placed on sick leave. —— Passed Assistant Surgeon W. G. G. Wilson, detached from the Minnesota and ordered to the Pinta. —— Surgeon Charles H. White, ordered to the Museum of Hygiene, Washington, D. C. —— Passed Assistant Surgeon J. H. Bryant, detached from the Museum of Hygiene, and ordered to the Miantonomo. —— Passed Assistant Surgeon D. M. Gutierrez, ordered to the Navy Yard, Pensacola, Fl.

Society Meetings for the Coming Week.—Monday, September 3d: Medico-Chirurgical Society of German Physicians; Morrisania Medical Society (private). Tuesday, September 4th: Medical Society of the County of Hudson, N. J.; Virginia State Medical Society (Rock bridge Alum Springs—first day). Wednesday, September 5th: Medico-Legal Society; Virginia State Medical Society (second day). Thursday, September 6th: Virginia State Medical Society (third day).
Lectures and Addresses.

CLINICAL LECTURES ON
DISEASES OF THE SKIN.
DELIVERED AT THE NEW YORK HOSPITAL.

BY L. DUNCAN BULKLEY, M.D.,
PHYSICIAN TO THE OUT-PATIENT DEPARTMENT—CLASS OF VENERERAL AND SKIN DISEASES.

LECTURE II.

Squamous Syphilide simulating Psoriasis.—Tubercular Syphilide resembling Lupus.—Tubercular Syphilide.—Favus.

CASE I. Squamous Syphilide simulating Psoriasis.

—Gentlemen: I first present you to-day the case of a man thirty-three years old, peculiarly interesting as coming after the case of psoriasis which I showed you last week. I mentioned that the only eruption which that particular case could resemble was the small papular syphilide, and I called attention to certain features of psoriasis which I said did not exist in the former disease; in the papular syphilide you will see lesions which you do not find duplicated in psoriasis; and I think I can point out many elements and features which will enable us to make a complete and clear diagnosis, without asking him anything as to the history. You see it does not resemble very much the case of psoriasis; for instance, the lesions are grouped together quite differently. You may see a large papular syphilide like a large spot of psoriasis scattered over the body, and if you examine all of the eruption on the body you will find some of the lesions grouped together, from which you are enabled to make a diagnosis.

In this patient you find scaling, but the scales are white, less adherent, and not branny. This is a simple crust, and I can pull it off with the greatest ease. Another point is that when the crust is removed you do not find the bleeding eorium beneath, and it is well worth remembering. He has had this eruption on the body and limbs for five months. On the lower limbs you see what one might say, if seen alone, was psoriasis. If that was presented to me from the knees down, and nothing else, I confess I could hardly make a diagnosis. If a man refused to show me anything but that, or if I did not examine close enough to find anything but that, I might say it was psoriasis. You find the moist scales heaped up, and you pick the mass off, and reveal the bleeding of psoriasis, and this scale is adherent. The difference between those scales and those of psoriasis, is, that these are thickened and filled with a deposit. A feature of the syphilide eruption is found in its situation in the bend of the elbow. Here we find it in the prominent position of psoriasis, namely, on the extensor aspect of the arm, just above the elbow. I never speak of syphilitic psoriasis. Psoriasis is a distinct disease. We do not meet with a psoriasis due to syphilis, or a lupus due to syphilis; but we do meet with a tubercular syphilide. After this eruption has disappeared you will see a stain left.

CASE II. Tubercular Syphilide resembling Lupus.

—This patient is a man, aged thirty-three, married, a sales-

man, sent here by Dr. Raphael. His children are healthy, and he enjoyed good health till about ten years ago, when he first noticed some spots that appeared on his face and body, which were pronounced specific. Previous to that he had a crack or fissure of the upper lip which would not heal. He was treated for syphilis, but he felt convinced that the physician was wrong in his diagnosis, as he had never exposed himself, and never had had any sore on his genitals. The physician gave him mercury and iodide of potassium, which produced on his forehead just such sores as he now has on his lip. He was under treatment for six months without any benefit. He was next treated by a homeopath; he had a sore on his leg which healed up, but that on the forehead would not heal. He next took arsenic, and had escharotics applied to the sore on the forehead, with no result. He discontinued the use of escharotics, but took medicine internally. Seventeen months ago an angry red spot appeared at about an inch above the angle of the mouth, on the right side. This sore appeared soon after using Wei de Moyer’s snuff for a catarrh of the nose. It went on to ulceration and suppuration of the nose and lip, that on his forehead healing up about that time. For the past ten months he has been treated by various remedies, and six months ago his face was almost entirely healed. But about that time he had an attack of erysipelas of the face, scalp, ears, and eyelids, from which he got well, and after that the sore was healed, all but a minute spot, which looked very much like an obstructed sebaceous follicle, and from that the sore spread again and continued to grow worse till it assumed its present condition.

Whether this is a case of chancre of the lip I can not tell; he says he has never exposed himself, and you see these cases occasionally where you can get no symptom of chancre except that the sore will not heal. A scar of the diameter of one on his leg, without varicose veins, upon the upper third of the leg, pigmented and soft, is in a good many instances syphilide; I mean, you can take that always as a grain weighing in the balance. Look closely, and notice the great amount of inflammatory induration associated with and surrounding the outer edge of this sore, and notice that there are no elements which we can call tubercles, such as we see in lupus—namely, soft, pultaceous things that have a branny scale, and break down in inflammatory ulceration. The supppeness of this scar—a decided scar that will remain for life—is characteristic. Notice the inflammatory elements of the ulceration, and its slow, lymphatic character. Now, the question of diagnosis arises between syphilis and lupus. In the first place, he has not had any specific treatment for four months, and the eruption has resumed the condition which it had before, which favors the belief that it is specific. Suppose he had not had this specific treatment, suppose he was a foreigner and could not tell what he had done, or you saw him for the first time, could you make a diagnosis from the appearance alone? I hold that you could. There are elements here that are not seen elsewhere. In the first place, lupus is extremely rare indeed in this country. In looking over some statistics, I find in the out-patient practice over ten per cent. of all the
cases were specific, while in private practice there were only five per cent.; that was astonishing to me, and it was astonishing to me when I got the figures to find how few cases there were of lupus. In about 8,000 patients there are only about 42 in the list. I have seen these syphilides burned out by caustics, nitrate of silver, etc., and cured for the time being. They will heal if you excite sufficient inflammatory action, but they will be sure to break out again, as in this instance.

Secondly, you do not have any inflammatory edge. In lupus you find more or fewer tubercular nodules.

Case III. Tubercular Syphilis.—I want to show you now a patient that Dr. Allen sent here with almost precisely the same physical features a week or two ago, vastly modified to-day by treatment—that of a man, aged forty-two. Two weeks ago this lesion you see on the lips resembled exactly what you saw in the last case, but is now modified by the treatment he has received. You see how quickly the inflammatory action subsided under proper treatment. A better illustration could not have been found for clinical demonstration of two cases so closely resembling each other as these did two weeks ago. There was some little doubt in the diagnosis of this case, and the patient was put on active specific treatment, with the result you see. Within three weeks or a month that induration will be entirely gone, leaving nothing but little red stings and a scar.

Case IV. Favus.—This man I show you first exhibits favus, most characteristically, in a way that you could not mistake. He came from Hungary, and was admitted two months ago, during my absence from town. He has been in this country nine months; has a sister, twenty-three years old, who has no eruption; his brother in Austria had it for several years, and is now well. He is now nineteen years old, and his brother is some years older, and had the eruption some time, but has been cured, according to his account.

The characteristic lesion of favus is a yellow cupped crust formed upon the scalp or elsewhere, which is soft and friable, and comes off easily. You will see these yellow cups standing on a yellow base, and there are cases where there is cicatricial tissue, with all the hair gone from it.

What the condition was when this man came here I do not know, but it was put down as eczema of the scalp. He had been applying ointments and had been under various treatment, and there is no blame for the wrong diagnosis, because the diagnosis of favus cannot be made without treatment. I can treat this patient, and a week from now no one could make a correct diagnosis. When the hair is growing well, it is difficult to recognize the favus. When I came back some of the cups were springing up, and the diagnosis was very easy to me, but had been very difficult to my assistant in my absence; but the eruption is better to-day than it has been. The only way to make the diagnosis, when you can not make the proper examination, is to leave it alone for a sufficient time to have the cups formed.

What you see here under the microscope are a number of small tubes of uniform size, and of a slightly greenish tint, with rounded extremities. The products of <i>Tinea trickophytina</i> are smaller than these, and those of <i>Microspora furfur</i> are smaller yet.

How are the crusts of favus prepared for the microscope? In the simplest manner possible. The material that you take wants to be laid on a slide and moistened; water will do perfectly well, although I prefer two parts of glycerin to one part of liquor potassae. Taking your knife and breaking it up, you will see the whole field covered with spores. Any one of these spores is enough to propagate the disease. You may see hundreds and thousands in the field, and you see how difficult it must be to get rid of all of them.

Case V. Favus (Case No. 2).—There is very much more difficulty in diagnosis in this woman's case. I question if any of the gentlemen would be at all able to make the diagnosis. It was supposed to be eczema; there were certain portions of the scalp slightly scarred, which we know does not come from eczema, psoriasis, or seborrhoea, from which you never observe a scar. I have left her three weeks without local treatment, although I have given her rhubarb, etc. It was only by waiting several weeks for the growth that we could make our diagnosis; but here to-day I make my diagnosis. I make it from the hairs, and to show the difficulty in this case I will state that two of my assistants searched the hair and thought it was not favus, and I searched the hair and found none, but on the second search that I made I found two hairs that were affected by favus. After several examinations by persons accustomed to it, it was not found until to-day, when I searched for it in my office. The disease is quite common in Austria and Hungary, and in Glasgow, but it is particularly rare here. Now, you get through here a slight amount of crusting, and then here is a slight amount of scarred baldness, and you look in vain for any open hair follicles; you see simply scarred tissue. This is important in these milder cases, and they go on for years, but with proper treatment they could be cured. Here, gentlemen, you see a sulphur-yellowness of this one little cup. There is a peculiar smell when there is enough of the disease, but not when it is very slight. There is a trilling change of color in the hair; one portion you see is moist, and another portion you find dry and harsh, and that attracted my attention.

As I said, we can improve the nutrition very much; but here is a curious thing: that almost all people who have favus, if they are cured of their favus, or if the disease is largely removed, their general health is improved without treatment; in other words, the growth acts as a depressant itself.

What is the local treatment? Some years ago Bennett offered to cure these cases of favus with cod-liver oil, and it was a wonderful failure. For a time there was great talk of Bennett's treatment of favus, and he exhibited a number of patients who were said to be cured; but after a short time those patients turned up at other clinics. He thought they were cured because the surface cleaned off and the hair was growing. They were not cured. If I had this patient here in the hospital a month, and good attendants should see him every day, he could not be cured in three years perhaps, not in six perhaps, certainly not in a year, because of
the character of the disease, for the parasite burrows into every individual hair follicle to its extreme depth, and produces ulceration and destruction of the follicles. To cure it, every hair must be pulled out. If you shave off the hair and apply an ointment, and if the patient does not die in the mean time, you may possibly cure it, but I do not think the mere application of ointments will cure it in a lifetime. To really destroy the parasites you must penetrate the sheaths of the hair, and therefore you must pull every hair out. This treatment then may be followed as a wholesale depilation, by tearing off the whole at once with a stick made of wax and tar, which is made to adhere to the hairs and then pulled off. If you pull them out with the forceps, one at a time, you will be surprised to see how many hairs the human scalp contains; while on the other hand, if you pull them out with a stick, you pull out hundreds at a time. The hairs come out very easily, and when they come out they are laden with the parasite.

Original Communications.

AN OPEN LETTER TO COUNTY MEDICAL SOCIETIES IN THE STATE OF NEW YORK.

By SAMUEL S. WALLIAN, A. M., M. D.,
BLOOMINGDALE, N. Y.

As a member of two county organizations, familiar with the trend of recent discussions (both secular and professional) of the code question, and aware that a large number of county societies have declared against the existing State code and in favor of the Code of the American Medical Association, I desire to suggest a few practical points which will sooner or later present themselves for consideration and settlement. As medical men we demean ourselves by approaching this touchy subject of the code in a spirit of partisanship or prejudice, but should discuss it with the same poise and candor with which we would analyze a case in diagnosis. Unfortunately, there are too many who are so blinded by partisan zeal as to resist every appeal to reason and who will go on to the end (of life, perhaps) asserting allegiance to a code—new or old—the spirit of which they have never fully understood, and the letter of which they have scarcely honored.

It ought not to be necessary to remind members of the legal origin and prerogatives of their societies, but an apparent obtuseness on this point seems to be the primary block of stumbling.

The act of 1806 duly incorporated the Medical Society of the State of New York, and authorized the formation of the several county societies as auxiliaries. The prime and sole condition on which depend all chartered rights is the enactment of by-laws, rules, and regulations (code) for their own government, which shall not be repugnant to the Constitution of the United States or of the State of New York, or inconsistent with the by-laws, rules, and regulations (code) of the Medical Society of the State of New York."

Whenever a county society enacts a set of regulations (code) "inconsistent" with the regulations (code) of the State society, it simply and from that moment causes to have any legal existence. It becomes, to use a political term, a rebel and seceder. Granted that the regulations (code) of the State society, through the tinkering of schemers and would-be reformers, have been made obnoxious to a large number of the constituency of county organizations, secession is not the method of cure. It is contrary to the spirit of a democracy, and contrary to common sense. On the other hand, this illogical course only confirms and perpetuates the bad legislation indulged in by the parent society. This principle is too thoroughly established and too generally acknowledged to require any formal corroboration.

Taking the action of the Essex County Society as a sample of what others have done, a majority of 6 to 1 (18 to 3) declared by resolution, at their annual meeting in June last, that they repudiated the existing code of the State society, and reaffirmed allegiance to the code of the American Medical Association.

Hence, since the 26th day of June, 1883, the Essex County Medical Society has had no legal existence.

True, this question of loyalty was not broached at the last meeting of the State society, but, after the acrid, and, in some instances, unseemly and indescribable agitations of the subject which have occurred in certain quarters, it can not be expected that the champions of either side will hereafter waive any of their legal or chartered privileges, but will hold every auxiliary society to a strict allegiance to the letter and spirit of the law.

It is folly to hoodwink ourselves on this point. The law is by no means ambiguous, and no rendering of the English language can give it any other construction.

If any modification of the existing and, to many, obnoxious State code is to be made at the next annual meeting, it must be done by the votes of permanent members and of the delegates of such county societies as have adopted a set of regulations (code) not inconsistent with the regulations (code) now governing the State society; in other words, not inconsistent with the so-called "new code." The code of the American Medical Association is "inconsistent," etc.; hence, Essex County, in her present dilemma, and all other county societies which have taken similar action, can have no voice or vote in either confirming, amending, or abrogating the obnoxious code.

Delegates from societies which have committed themselves to this unpatriotic and undemocratic course must, of necessity, be refused recognition—it is to be hoped not in any such spirit of discourtesy as was displayed at St. Paul last season!

It can not be expected that the spirit of deference shown by the advocates of the new code at the last session, in not insisting on strict loyalty on the part of county societies, will prevail during another session. Too much feeling has been aroused; all weapons will be used and every legal advantage availed of.

Have country members, who have unthinkingly—perhaps only instinctively—thus committed themselves to virtual secession, really looked this question in the face, and
are they ready to be thus summarily disfranchised, as regards participation in the proceedings of the State society?

There is no need of consulting the courts. The law is so plain that a wayfaring man though a doctor, even, need not err therein. The average school-boy can expound it without fear of tripping.

There can be but one remedy, and that lies through a manly reconsideration of the unwise and ill-considered acts of secession—for such they surely are—and a simple declaration acknowledging the existing State code. Then, if thought best, a further resolution may set forth critical objections to any obnoxious features of the existing code, and instruct the delegate to use every endeavor to bring about desired changes. This is the only rational, honorable, and democratic method of correcting legislative evils.

What would be the spectacle of a board of county supervisors "repudiating" the acts of the last session of the State Legislature, and enacting laws more congenial to their wants or feelings? Stupid as such action would appear, it is not a whit more absurd than is the recent action of certain county medical societies.

Should the recalcitrant or seceding counties refuse or neglect to adopt this eminently proper, rational, and honorable course—the only course by which to recover what they have now unquestionably lost, viz., representation in the State society—there is but one alternative open to "loyal" members of county organizations, if they desire to be represented at the next annual meeting of the State society. They must call a meeting of those who hold to democratic and legitimate methods of settling ethical disagreements, organize county medical societies de novo in their respective counties, enact a code of ethics "not inconsistent," etc., elect a new delegate and send him to Albany with formal credentials, where he must necessarily be recognized, to the exclusion of any who may base claims on credentials issued by the old and (legally) dead societies.

Gentlemen of the county medical societies, are you ready for the question? To which horn of this dilemma are you inclined to fasten?

Members of the Essex County Medical Society, will you right yourselves and be represented at Albany by your old (and tried) delegate, or by one of the "lonesome three" who refused to secede? In other words, having voted to commit felo-de-se, will you insist on dying, or will you, as handsomely as may be, recover yourselves while the way is yet open?

THE PATHOLOGY OF ACUTE LOBAR PNEUMONIA FROM A NEW STANDPOINT.

By WILLIAM D. SCHUYLER, M. D.

(Concluded from page 235.)

Third. If further argument were necessary, it might, with equal reason, be drawn from the results of the process upon circulation. We should ask how depuration of the poisoned blood is promoted in and by the lungs by its obstruction in those organs? We know the blood is obstructed by the pneumonic process because of the induced arterial anemia which results on the one side, and the hyperemic condition of the veins or afferent vessels resulting on the other. In other organs increased function is caused and sustained by an increased rapidity of circulation through them; which is not the case for the lungs in this malady. Although these organs are hyperemic in the stage of engorgement, in the area where the process is forming, and in collateral areas throughout until crisis or advanced resolution occurs, yet this hyperemic condition differs markedly and in two particulars from that congestion which promotes functional action: First, it is a passive, inflammatory congestion, rather a simple hyperemia; while the congestion which increases function is determinative or active. Second, this is a hyperemia of carbonic blood, which excites respiration only, and does not stimulate but depresses other functional activities, while an increase of general function action depends upon a determination of arterialized blood. These organs, then, being obstructed, blocked with blood, instead of being in condition to circulate it more rapidly than otherwise, can not be held to exercise in this state a blood-purifying action.

Fourth. How can it be maintained that by this process the entire volume of the blood is depurated of a poison through an exudation which immediately solidifies or consolidates the pulmonary area into which it is poured, and completely inhibits its further functional capacity; how, by this action, can the remainder of the blood not involved become cleansed?

As the blood leaves the right ventricle, and enters the pulmonary artery, its character must be even throughout. No selective process which has determined a contained poison to one fraction of the systemic stream can have taken place before this fluid reached the right heart; and certainly none can act while it is in this organ, or while it is further passing the two inches comprising the length of the pulmonary artery. Hence, as the blood divides and enters the right and left pulmonary arteries, the composition of the two streams must be the same. And, if one division has the potency to create local trouble for eliminative purposes, the character of the other division should be equally potent to set up a like action; which affords an especial reason for deciding that, if a deporative action causes the local process in this disease, it should occur in both lungs and by many foci, and not as a concrete or partial condition, as is developed.

But the point I desire to make in this place is, that, as only a portion of the blood even in many circulations can evacuate its poison in this confined exudate; and as it is doubtful whether there is a further circulation through the area which becomes consolidated after the primary stoppage, this supposed blood-purifying process is a failure. It is more reasonable to suppose that an elimination is not intended.

For the various reasons given, I submit that the local affection is not depurative in character, and, if not, it follows that it is not a manifestation of an infectious disease. The likeness of the malady to the essential pyrexie is, therefore, not established, and the hypothesis that acute lobar pneumonia is essentially an infectious fever fails also.
There is one point more to be considered against the pyrexial hypothesis, which is, that fever is an irregular and inconstant manifestation in the process. It is a familiar observation that there is a want of established correspondence between the extent of the local lesion and constitutional symptoms, or fever. In some cases the pyrexial phenomenon is very marked, in others, on the contrary, it is a feeble manifestation, and, in others still, there may be a lack of fever throughout.

While the data in regard to the latter fact are not numerous, yet there exists sufficient evidence upon which to establish its possibility. While I have met with many cases in which the maximum of fever did not reach above 100° or 101° F., I have attended one well-marked case of the disease, seen on the second day of the attack, and while consolidation was yet forming, in which the thermometer, carefully placed and well protected in the axilla, did not register above 97° until after three days of tonic stimulating treatment, which increased the temperature to normal. This case occurred in a German, single, aged twenty-four, a grocer's clerk, whose living had been irregular, and who, insufficiently clad during the preceding winter months, had been subject to daily early morning exposure in the market. He stated that he had not been strong for some weeks prior to his attack; he denied having had a chill, or having experienced thirst or heat. His symptoms were weakness or great debility, loss of appetite, rusty sputa, slight in amount, and scanty urine.

In regard to apyrexial cases, Wilson Fox says such must be exceedingly rare. Yet, as not wholly denying but granting their possibility, he gives the statement of Grisolle that "in some cases the course of pneumonia is apyrexial throughout, though the physical signs and rusty sputa are present; and of Wunderlich, who repeats or justifies Grisolle's statement.

Jürgensen says, in regard to this point: "I do not wish to deny that, in a highly cachectic person who is attacked with pneumonia, the temperature of the body may possibly remain normal. And, the 'walking cases' referred to by Flint without doubt belong to and illustrate this class. At any rate, the lack of a more pronounced febrile expression in a large proportion of cases is to my mind conclusive that fever is not the essential pathological factor in the genesis of this malady."

Although the temperature curve exhibits characteristic features, which may give it a seemingly essential importance, yet I hold that the expression is irritative simply; and that its distinct characters are to be explained by the development of an equally characteristic cause, the local pulmonary anatomical process, which is essentially the disease. The fever manifested is without doubt an expression of the irritation which the formation of this process sets up in the system of the person attacked, and its degree depends wholly upon idiosyncrasy, temperament, and existing vital conditions.

It is upon this ground that we can explain the comparative apyrexia of the cachectic and physically depraved, on the one hand, which, in certain degrees, may be observed in daily experience; and the high grade of fever which attends the process in the young and otherwise robust, or nervous, excitable subject, upon the other. And I may mention here that, in my opinion, this variation of grade of fever dependent upon tonic, aesthetic conditions, as it occurs in pneumonia, constitutes a point of difference between it and those pyrexiae which are essential. In the latter, as a rule, the higher grades of fever are developed in the more depraved subjects.

It is upon the ground of idiopathic states also that we are able to explain the want of a general relation between the local and constitutional symptoms referred to especially by Jürgensen.

The irritative character of the pyrexial manifestation of pneumonia is rendered probable from its inconstancy and irregular manifestation; its concurrence with the commencement and formation of the local process; its accession whenever the local process is extended; by the fact that deference sets in when exudation is completed and is perfect with the occurrence of crisis; also, because it has the same typical course when the pneumonic process follows after traumatism; and, lastly, because the temperature curve does not coincide with the same phenomena of the essential fever.

If other reasons were wanting for abandoning the theory that the pyrexial manifestation of pneumonia is the essential element of the disease, they may be found in a consideration of the following questions: What purpose is served by giving to this fever the prominence which attaches to the term "essential," and according it a special name? By the designation of "febris pneumonica" is any quality of the malady elucidated which renders the important indications for treatment more clear, simple, or emphatic? On the other hand, does not such prominence act injuriously by withdrawing attention from indications of vastly more importance than those which arise in connection with the pyrexia?

In other fevers the classification illustrates to the student the main indications to be met. Can a like advantage be claimed for the special designation in this case? For "malarial" fevers we know that, with a regulation of functions, quinine and arsenic are curative; in the essential fevers, although we know there is a strong tendency to self-limitation, yet the pyrexia comprises the source of danger, and therefore its management, with an equal regard for the support of our patient, furnishes the indications to be met.

In the exanthemata, more definitely limited than typhus or typhoid, fever is also the dangerous element, and of the first therapeutic importance. But this febris pneumonica! Its bearing, considered as a fever simply, upon the prognosis of the pneumonic process is a secondary matter; there is no element of danger in it; it rarely reaches 103° uncomplicated, and generally its range is from one to three degrees lower, and downward; furthermore, at a comparatively early day, from the third to the eleventh, of the disease, generally from the fifth to the seventh, it terminates naturally, being one of the phenomena of crisis. In this malady, therefore, beyond being an index of the progress of the local affection as we shall see, the febrile manifestation is of but little account, which being true clinically, why give it the dignity of an "essential"?
As we shall see, the phenomena which involve the elements of danger in this pathological process, which therefore should be watched and most carefully studied, are directly or indirectly connected with the pulmonary lesion, and have regard to two momentarily vital functions, which are imperilled by it. These are, in the earlier periods, the respiratory function, which, being inhibited, may result in death from apnoea; while in the later or more advanced stage the circulatory function involves the weak point, when death may occur on account of right cardiac insufficiency. These dangers will be more especially characterized in my study of the morbid physiology of this malady.

The important prognostic signification of the local lesion and the unimportant character of the pyrexia render, to my mind, any undue prominence which may be given to the latter questionable, if not positively harmful, teaching. Hence, on the ground of clinical importance, considered in the light of the dangers inherent in the malady, and also for the scientific reasons advanced, I must refuse to accept the hypothesis that acute lobar pneumonia is to be regarded and treated as an essential fever.

The Local Process is not inflammatory.—Although the grounds for maintaining that the local process in pneumonia is not an inflammation will be more manifest after a careful analytical study of the process itself, anatomically and histologically, which will be given in a following article, yet the general facts in evidence may be briefly referred to here, and summarized as follows:

The Character of the Process as a Whole.—Its rapid development, considering the extent of the lesion, and especially considering the amount of the exudation poured forth, the nature and facts of its limitation—it does not extend as an inflammatory process to the delicate overlying pleura, or communicate a like action to the enveloped bronchial mucous membrane (though both of these structures are involved, the action set up in them, judged of by its results and transient character, is to be regarded as a passive congestion, rather than as an inflammation); the singular character of its abrupt termination, spontaneously, by pressure or with the consolidation of the lung structure involved; the mode of its extension when such occurs, not by a slowly advancing process of contiguous action, but by involving a considerable extent of pulmonary structure quite suddenly, as by a stroke; its changing character as a process of development or retrogression, and the rapidity of these two actions; its speedy early removal, and the fact that after its removal the pulmonary structures, which have been so completely involved, are found not to have been injured anatomically or functionally, except in a nutritive sense—these phenomena are most unlike those of an inflammatory process, and strongly negative the hypothesis of such an action.

The Nature of its Results—namely, of Congestion, of Exudation, and of Consolidation.—(1.) The congestion which occurs in the stage of engorgement, and constitutes the first result of the primary lesion, is special, and, I may say, has no counterpart in pathology. It is not an active event, but is a passive resulting condition, occurring on account of the pulmonary obstruction created, on the one hand, and a local filling by the constantly arriving, inflowing blood, on the other. Unlike other forms of hyperemia, this congestion is not the result of an irritative determination of blood to the locus morbi, and maintained by a rapid passage through and out of the affected part; but the vital fluid comes to the part in a natural way, and at first in normal volume, and its local increase is due simply to its passive retention. Again, in this congestion there is no rapid change and renewal of blood in the involved portion of the lung corresponding to the renewal of this fluid in other parts or organs affected by inflammation; but, instead, there is a local stagnation of blood, which fluid is changed only in amount by addition from natural physiological causes. The blood that arrives first remains, or, if it passes through into the efferent vessels, does so very slowly. And this fact of the non-renewal of the blood which furnishes the exudate, or its renewal being by addition only, I have already pointed out as negatively an eliminative action for the local affection, especially as regards the entire volume of the systemic blood.

In a following article, embodying "analytical considerations of morbid anatomy," I shall show that this congestion is, according to the capacity of the affected capillaries to distend and resist pressure, an extreme result; also, that its resolution, which follows directly after maximum congestion is reached, is accomplished by lateral pressure.

The facts, then, that this congestion or engorgement is strictly passive from obstruction and filling; that it is not composed of renewed but stagnant blood, and is increased by accumulation merely; that it is limited, not by a change in the irritant nature of the causal influence, but by extreme vascular capacity; that its resolution is the result of lateral mechanical pressure; and, lastly, that it is composed of venous instead of arterial blood—make it unlike an inflammatory congestion.

(2.) The nature of the exudate, which is the second result, and forms the anatomical element of consolidation, is not inflammatory. Its excessive amount, as compared to the amount of an undoubted inflammatory exudate of like grade and character, the latter being hemorrhagic; its course, formation by simple conglutination, firm consistency, brief duration, immediate degeneration, ready liquefaction, and complete disappearance by absorption and expectoration, are unlike that of any other exudate, and can not be regarded as inflammatory. The brief time required for the removal of this exudate, considering its amount, has no parallel in an inflammatory exudate of like histological constituents.

This exudate consists histologically of preformed elements, the result of normally acting nutritive functions, in which it differs from any inflammatory exudate, which consists of newly formed elements, the result of deranged and abnormal nutritive forces, and these elements again vary according to the degree of each inflammatory process.

One of the results of this exudation and its formation is consolidation of the affected lung structure. This consolidation, by the rapidity of its formation, solidity, transient character, and in leaving no sequelae other than debility, is unlike any inflammatory exudate.

(3.) The fact that this process as a whole, while forming,
resolving, or as completed, causes or has caused no alteration of the pulmonary structure, except as noted, either in the vascular or connective-tissue elements, corresponding to well-recognized results of every grade, or any grade of inflammatory action in other structure, or when such action is had upon the lung structure itself, as in bronchitis, chronic bronchitis, pleuritis or phthisis, is most conclusive proof that neither the action nor the results of this process are inflammatory. And it is quite as significant, as showing a non-inflammatory action for this process, that throughout, although these organs rapidly in every minute section of the involved area, the lymphatics are uninjured and continue their function. That they are continuously active throughout, we may conclude by observing the increased amount of fibrine found in the blood after this process begins, and by the more apparent increase of coloring matter in the urine, the haematin of the disintegrating red blood-globules which is being exerted through their action.

In support of the fact that the pulmonary structure is uninjured except from temporary innutrition by this process, we have the evidence first of clinical observation, which through physical examination finds the affected organ, at an early day, resuming its complete function. Second, we have the evidence of authoritative histological observers. Rindfleisch ("Pathological Histology," p. 425, 1872) says: "A recently hepatized piece of lung is injected from the pulmonary artery with a blue gelatinous mass, then hardened, and thin sections made. Upon these sections we find the alveolar walls exactly constituted as though we had injected a perfectly healthy lung (a), the same number of intervascular and vascular nuclei, that most external layer of scattered, rudimentary nuclei which we regard as the remains of the epithelium, all unchanged. And yet within the lumen of the alveoli there is a finely filamented coagulum (b) which incloses numerous colored and colorless cells." He goes on to say (and this I consider important): "The cells must therefore proceed directly from the vessels they must have passed through, migrated through their walls, although we can not discover the slightest abnormal opening upon the walls. This evidently complete microscopic observation establishes so far the fact as stated, that although exudation has occurred, has filled the air-cells, and therefore is complete, yet the alveolar walls have not suffered, but are found to be in the same patent condition as in a healthy lung; and the remaining element of the pulmonary stroma, the capillaries, shows no abnormal opening upon their walls.

For further and corroborating evidence upon this point we refer to Delafield ("Studies in Pathological Anatomy," 1882), who says: "In the earlier stages of red hepatization the vessels of the lungs are full of blood, the walls of the air-veisicles are unchanged. Although the blood-veins are full of blood, it is not coagulated, and the vessels are easily filled with an artificial injection after death. This recent and, as we know, careful author not only confirms the truth of Rindfleisch's observations in regard to the condition of the air-veisicles, that they are unchanged, but he carries us still further; he tells us the blood in the vessels is unchanged, "not coagulated," and that "the vessels themselves are easily filled with an injection after death." From which we may justly infer that the internal vascular tunic, as we have seen of the vascular walls externally, is uninjured. The fact that the pulmonary capillaries can be injected at any stage of the pneumonic process, with little or no considerable force, is well known, and does not require further confirmation.

From the facts already given, then, we have a complete picture of the lung stroma, and we find every organic element of which it is comprised, and at the height of, or at any time during this action, uninjured; which is most conclusive proof of the non-inflammatory or negative character of the action which has taken place. The opinion that there is no inflammatory impairment of the lung, and hence that there has been no inflammatory action present, is further corroborated by Flint, who says, "In favorable cases, after the removal of the exudation, the air-veisicles are found to have sustained no damage."

That the process at work in the local affection is not inflammatory we may decide, furthermore, from the negative results of the degree of the existing action in general, and by the absence of anything like more or less permanent sequence after its termination. The anatomical character of the pulmonary structure, its highly predominating vascular element, its connective tissue stroma, and the loose arrangement of these, being everywhere permeated by the air spaces, favor serious results, destructive, or at least more or less permanently adhesive, from a true inflammatory action. The capillary vascular supply, the rich character of its plexus, of which Kölker says: "It is one of the closest in the human body," of itself, considering the acute nature of the manifest action being hemorrhagic and, therefore, of high inflammatory grade, would especially favor destructive results from inflammation. The minute character of these capillaries, which Atkken says ("Science and Practice of Med.," p. 794) "average only from \( \frac{3}{1000} \) to \( \frac{9}{1000} \) of a line in diameter," and their nearness to each other (the pulmonary capillary meshes are only 0.002' to 0.008' in diameter [Kölker]), favor—the one, destructive effects upon the capillaries by their more or less perfect closure, the other, their general cohesion into one mass.

The structural arrangements of the entire pulmonary elements, as well as their histological characters; their closely contiguous yet distinctly separate parts, favor adhesive results from inflammatory action such as occur in pericarditis or in basilar meningitis. The acute nature, as stated, of the manifest action per se, and the grade of such action as indicated by its resulting exudate, justify for such action more or less permanent pathological circulatory or respiratory results.

But when we recall the fact that, although this action occurs in a structure so abundantly supplied with capillary vessels, and so favorably constructed anatomically for adhesive results, that it causes an abundant fibrinous and hemorrhagic exudate, and that this exudate solidifies and distends the entire organ, that the structure immediately involved histologically favors at least adhesive results, and yet such sequence does not occur, it is reasonable to con-
clude that it—such action—lacks the essential or true inflammatory element.

Again, if the action were inflammatory, the grade manifested in every sthenic case should end in a destruction of the parts involved, either anatomical or functional. This deduction, I claim, is quite admissible in view of the fact just referred to, that in pericarditis with a like sthenic action—not more so, as judged by the general symptoms—the opposing serous surfaces become joined in spite of the free cardiac movements which make adhesions vastly more difficult than where similar structures are affected in this process which have comparatively little relative action.

Furthermore, if there were present in this process, as the cause of its action, the essential character of an inflammation, estimating the extent of the structures involved, there should be some degree of pulmonary phlebitis and inflammatory stasis; some results of such action on the distal side of its original and primary site, as a sequence of which, when resolution takes place and this material breaks up, there should occur, as in any other phlebitis, and especially so if, as is claimed, the genesis of pneumonia resides in a blood-poison, many and innumerable emboli and their consequences. As there is no stasis of the blood in pneumonia, and as there result no embolic sequelae in the course of its resolution, we may for these reasons also conclude there has been no inflammatory action.

A study of pulmonary infarctus from embolus, just suggested, which embodies a condition of hepatisation so called, and its consequences, and which comprises a degree of infarcted peripheric inflammation, and a comparison of its course and results with those of a pneumatic action, also argue for the latter a non-inflammatory character.

Briefly recapitulating: The facts that the lung stroma has received or sustained no damage; that the exudation does not conform to, is not adequate with or like an inflammatory exudate, which will be more definitely shown later on; that lymphatic action is not inhibited—render the hypothesis of an inflammatory action for this process untenable if not conclusively negative.

But the equally significant facts that this process is not caused by contiguous inflammations, and does not communicate them; that it can not be produced by any of the usual causes of inflammation, however strong or weak their action; that it is always developed irrespective of extrinsic agencies of whatever character acting directly upon the pulmonary tissues; that one important sign of an inflammatory action, an increase of local heat, both subjectively and objectively, is wanting—which symptom is present in degree in every acute inflammatory action, however small or circumscribed in area; that as a process it is more prone to attack certain localities of the lungs than others—which can not be explained upon the hypothesis that it is an inflammation, that it is continuously local, not diffuse—and, lastly, the fact that the process is developed from and by carabolic afflent, and therefore devitalized blood instead of arterialized blood, which is required to sustain an inflammatory action; and, that this blood is stagnant, not active, and is not renewed in the affected vessels—these many points fully corroborate the conclusion reached above, that the anatomical process of acute lobar pneumonia is not an inflammation.

Book Notices.

The aspirant for distinction in a special department of medicine rarely escapes the temptation to write a book. Till that is done he believes his success can never be assured. It is the most available while at the same time an honorable method of presenting before his medical brethren his claims to recognition as a competent specialist. The task of publicly reviewing his work, falling as it usually does upon a co-worker in the same department of medicine, is not always a pleasant one. To criticize it harshly seems almost as ungracious as finding fault with a letter of introduction. But self-advertisement not being the avowed motive of such a book, but rather the imparting of information to those not so well informed as the writer, the latter ought not to complain if the critic tries to indicate certain points in which the value of the work to the reader might be enhanced.

To begin with, the style of writing is a matter of some importance even in a purely scientific work. Perspicuity certainly is essential. Fluency in composition and beauty of expression, though less important, tend greatly to lessen the labor of reading. Involved sentences, unusual phrases, redundant or indefinite adjectives, add to the strain upon the reader’s attention, and may even become vexatious. To what extent the writer of the work before us has erred in these particulars would perhaps be too much a matter of taste for us to express a decided opinion upon. Sufficient it is to say that his promise given in the preface, “to write concisely,” might have been more scrupulously regarded.

The matter of Dr. Hyde’s book, consisting, as it mainly does, of materials drawn from authoritative sources, contains few questions of fact that require criticism. It is chiefly to the manner of elucidating the subjects discussed that exception may be taken. The descriptions of the different diseases, though in the main given with sufficient correctness, often fail to bring out as sharply as might be the features which are most essential. Matters comparatively unimportant, which may have impressed the writer because of their exceptional character, are sometimes made unduly prominent. Treatment is not, as a rule, defined as clearly as it should be. Much has been compiled in this connection that would bear pruning. The tendency has been rather to give an array of prescriptions than to systematize principles and indications clearly.

In our hasty perusal we turned first to the subject of eczema, unquestionably the most important subject with which the dermatologist has to deal. At the outset we encountered in the writer’s definition of the disease the somewhat vague expression, “one or several... lesions appear... either successively or simultaneously.” In the succeeding description of the disease appear several statements which, not being strictly accurate, are liable to mislead. Thus, the statement that popular eczema attacks “particularly the scrotum”; that erythematous eczema is especially common upon the palms and soles; that eczema ru-
brum is characterized by “dark-colored crusts”; that glycosuria may not be the cause of eczema of the genital region—at least such is the purport of the writer’s remarks on page 153. A somewhat exaggerated account is given of infantile eczema of the face, accompanied by “perverted mental tone,” of which an indication is that the child “will pick off and devour the crusts with voracity.” Pruritus causes the patient to scratch with “an incalculable [sic] savagery.” Reference is made to “Paget’s disease of the nipple,” but the points of differential diagnosis between it and simple eczema on the one hand and pronounced cancer on the other are very imperfectly given. In the matter of treatment the writer has little new to offer. We are surprised that his resources furnish him no better application for erythematous eczema of the face than “strips of raw beef,” a remedy suggested, perhaps, by the raw clam of popular ophthalmology. Finally, we think the writer fails to indicate with sufficient clearness the necessity of immovable dressings in infantile eczema, apparently reserving them for extreme cases only; and the virtues of the impermeable (rubber) dressing are passed over too lightly.

Through other portions of the book, among many commendable features, we discover some that invite further criticism. *Herpes proiginalis* is declared to be always the result of sexual erethism—too sweeping a statement. In his definition of zoster the writer makes no mention of the rule of nervous distribution, while prominence is given to such a non-essential and exceptional feature as the formation of cicatrices. His description of the localization of zoster is too partial and incomplete. He speaks of “disorders of deglutition and dental losses” in connection with zoster of the superior maxillary branch of the tri-facial as though common accompaniments. Eczthyma is declared to be due to a phlegmon; that is, inflammation of cellular tissue, apparently making it differ from furunculosis solely in the absence of a slough. Of molluscum, the writer says that it resembles “the lesions of variola more than any other cutaneous phenomena.” In what the resemblance consists, except it be in the slight umbilication of the former, we are at a loss to comprehend. This statement, if taken in connection with the singularly indefinite wood-cut given of the disease, would, we fear, scarcely assist one in making a diagnosis. Operating on these little tumors by excision or ligation, as advised by the writer, is, according to our experience, rarely called for. Simply pressing out the contents is usually sufficient.

We are surprised to learn that Dr. Hyde ranks chrysarobin as second to tar in the treatment of psoriasis.

A decided innovation is made by the author in considering *pityriasis rubra* and *pemphigus foliaceus* as varieties of a single disease, which he terms *dermatitis ex foliatica generalis*. We see no reason why, with equal propriety, *pemphigus vulgaris* should not be included under the same head. *Pemphigus foliaceus* is but a malignant form of *pemphigus vulgaris*, of which it not infrequently is the sequel. On the other hand, *pityriasis rubra* is never a vesicular disease, and never attended with moist exfoliation. Nor does it implicate mucous membrane as pemphigus foliaceus commonly does. Moreover, one is especially a disease of adults, while the other is quite as apt to attack children as grown people.

We are unable to agree with the author’s opinion that in syphilis non-parastricta epilation can be entirely dispensed with. We believe there are few cases in which removal of the hairs from the diseased follicles will not materially facilitate and curtail the subsequent treatment. But in *tinea trichophyta* the writer indorses the use of the “culotte,” a crude and crude method of epilation, which we had supposed had long been obsolete.

In speaking of the treatment of pigmentary diseases, the writer apparently mistakes the point of Hebra’s treatment by corrosive sublimate washes, the efficacy of which depends solely upon the fact that the application of a strong solution of the sublimate is not followed by superpigmentation, as a sinapism is, or as various other irritants are, but leaves a white surface afterward.

The *bacillus lepra*, as an aetiological factor in leprosy, is rejected solely on the strength of the investigations of Schmitt, which we think is showing scant justice to a large number of opposed investigators, whose conclusions are being more and more accepted.

On the whole, few of the defects that we have found in Dr. Hyde’s book are of a very vital character. Perhaps hasty writing would account for nearly all of them, which the revision of a succeeding edition (and we wish the author many) can easily remedy.

**Clínica Terapéutica. Tratado de Terapéutica Médica, ó Guía para la Aplicación de los Principales Modos de Medicación á la Indicación Terapéutica y al Tratamiento de las Enfermedades.** Por el Doctor A. Ferrand, Médico de los Hospitales de Paris, etc. Traducción del Francés por los Señores D. Pedro Espina y Martínez, Ex-Alumno Interno, etc., y D. Antonio Esquina y Capo, Premio Extraordinario de la Facultad de Medicina de Madrid, etc. Con un Prólogo-Introducción del Dr. D. Francisco Javier de Castro, Catedrático de Terapéutica en la Facultad de Medicina de Madrid. Madrid: Administracion de la “Revista de Medicina y Clirgía Práctica,” 1883. Pp. 815.

Dr. Ferrand’s “Treatise on Medical Therapeutics” comes to us for the first time in a Spanish dress. Of the faithfulness of the Spanish version we therefore feel scarcely qualified to judge; and our remarks will be confined to the matter of the book, and to the ideas which the author puts forth upon the vexed subject of therapeutic philosophy.

Dr. Ferrand, it may be observed, is a man who combines in no mean degree subtlety of reasoning with that lucidity of presentation which seems characteristic of the French writers. And so, with considerable ingenuity and with captivating plausibility, he has succeeded in evolving from one fundamental principle an entire body of medicinal philosophy, made up of many therapeutic propositions, mutually consistent and of apparently axiomatic certainty. And, though it is the tendency of scientific thought to look with great suspicion on systems reared thus in a day, and not built up by the slow and toilsome accretion of the labors of many workers, we can not but regard with much hopefulness any theory which will offer us an escape from the confusion which now reigns over the field of therapeutics.

The fundamental idea of Dr. Ferrand’s book is that of the indication. Instead, therefore, of considering, as Trousseau did, the facts of therapeutics in such order as would be suggested by a systematic treatise on drugs classified according to some preconceived theory, and instead of following out each disease, and the treatment which it demands, as has been done scores of times already, he has pursued a middle course. What this is will be seen more fully later on. The general plan of his book, however, is as follows: He first considers the two factors which must be regarded in the administration of a remedy. One is the disease, looked upon as an entity possessing a specific nature, a physiological form, and an anatomical seat. The other is the medicine itself, in regard to which we must learn—what the author is at pains to point out—the general facts relative to its introduction, its absorption, its elimination, and its mode of action. After this preliminary statement, the author proceeds to an investigation of the indications furnished by the various
conditions of health. Under this head he understands those afforded by the condition and temperament of the patient, by the age and sex, by certain physiological states, such as menstruation, pregnancy, and lactation, and by different conditions allied to disease, like obesity and the debility of convalescence, or that produced by irregular habits of life. Again, the effects of race, climate, profession, and diet, as determining the indication, receive consideration in separate chapters. In a discussion so general, of course, there is little to criticise. Most of the author's remarks are judicious, many are suggestive.

The bulk of the work is taken up with the statement of individual therapeutic principles and their application to special therapeutic practice. In doing this, Ferrand follows out a systematic classification of morbid action based upon what might be called the physiology of the latter. That is, disease is considered to be not so much a disorder of a special organ as the disturbance of a special function. Accordingly, in the first place, he regards disturbances of nervous function, then disorders of vascular action, then derangements of secretion and of nutrition, and finally alteration in the composition of the blood. And under each of these general headings subordinate divisions are made according to the special character of the functional alteration, whether in the direction of excess, of deficiency, or of perversion. Next naturally comes the consideration of those morbid actions which can not be regarded as mere perturbations of physiological functions—such, for instance, as inflammations, pyrexia, infectious and constitutional diseases, intoxications, and parasitic affections.

In treating of each variety of morbid action, the author pursues the same method: namely, he discusses first its characteristic features; i.e., its general morbid anatomy, macroscopical and microscopical, its symptoms, its course, and its results; then he takes up the subject of its causation and goes over this in considerable detail; then follows a description of the different kinds of induction whose fulfillment can oppose the morbid action, either directly or through its causes and in its sequels. After this, the varieties which this morbid action assumes in different organs are considered, together with the corresponding variations in the indication. Here the author enters so fully into detail as to give a brief account of his views of treatment of each disease, thus, in effect, adding a systematic treatise on special therapeutics to his general outline.

An example will perhaps better illustrate this system of classification and order of treatment. Let us take, for instance, the general heading of alterations of the blood-vascular function. Such alterations may, obviously, be either in the direction of excess (hyperemia), of deficiency (anemia), or of perversion (hemorrhage). Under the two former heads, Dr. Ferrand, after considering the general characters and general indications of excessive and diminished blood-supply, analyzes the specific treatment of congestion and of anemia of each of the organs, taking up, for instance, in succession, congestion of the brain and of the spinal column, congestion of the lungs, congestion of the gastro-intestinal tract (including hemorrhoidal congestion), and congestion of the liver, spleen, and kidneys, and finally the forms of congestion induced by fevers and organic disease of the heart; then treating of anemia in general, anemia of the brain (syncope), and anemia of the viscera in general, and especially of the uterus. In a similar way, the chapter upon hemorrhage begins with a description of its general symptomatology, its attendant pathological changes—conglutination, changes in the constitution of the blood, etc.—and the effects upon the viscera and the nervous system. Then follows a short general statement of the causes of hemorrhage somewhat after the manner of von Niemeyer. The therapeutics of hemorrhage in general Ferrand divides into the hygienic treatment, consisting of a series of physiological regulations against anything tending to produce rupture of blood-vessels or increased blood-pressure, and the medicinal treatment by means of haemostatics, astringents, agents modifying vascular tension, cardiac depressants, and the various revulsives. The therapeutics of special hemorrhages is considered in the following order: The hemorrhages of the hemorrhagic diathesis, and of purpura and scurvy with haemorrhidiosis, then hemorrhages of the mucous membranes, including bleeding from the mouth, hematemesis, enterorrhagia, bleeding from piles, epistaxis, haeamoptysis, humaturia, and metorrhagia; next, hemorrhages of the serous membranes and pelvic haematocele; next, parenchymatous effusions of blood, comprising cerebral, spinal, and pulmonary apoplexies, and apoplexies of the other viscera; and, finally, hemorrhages occurring in inflammatory conditions and in fevers, and hemorrhages due to septic or toxic agencies. In following an arrangement like this, the author is enabled to show how the general principles of treatment which he has already laid down suffice for all the various morbid processes which he enumerates, and how, nevertheless, the varying organic conditions impose certain restrictions upon these rules and render a special line of therapeutics necessary.

Such is the method which Dr. Ferrand has pursued rigorously throughout his book. The reader is, therefore, in a position, from the lengthy analysis which we have given, to form a just idea of the merits and the demerits of the work itself; for, it being assumed beforehand that the execution of the details is well done, the character of such a work must be determined solely by that of its methods. Our judgment of this matter can be readily summed up. Dr. Ferrand's system has the very great advantage that it tends to the production of a philosophical as opposed to a purely empirical method of treatment; it draws attention to the inter-relations of allied diseases on a common basis, and to the way in which their variations from a common type are constituted; and it shows how, in the treatment of every disease, there are two factors—the indication which determines it, and the form of the disease which modifies it. On the other hand, the system leads, it must be confessed, to somewhat arbitrary distinctions. We are not always able to fix so exactly upon the existing pathological condition as the author's scheme renders necessary. We are not able, therefore, to fulfill the causal indication; and yet, proceeding on the grounds furnished by the symptoms alone, we may arrive at satisfactory results.

A still more formidable, although allied, objection is the proposition of the empirics—that the indication is not a sure guide in treatment, inasmuch as, while fulfilling it, we frequently fail in curing the disease; and, on the other hand, we often succeed by the use of agents which answer no known indication. But this objection, we think, is founded in our ignorance of the methods in which drugs act. And, in any case, it will require little reflection to convince a thinking man that the science of therapeutics has advanced just in proportion as it has become less empirical and more philosophical; in other words, just so far as man has learned to use remedies not because they are good in certain diseases, but because he knows they do good in certain conditions. Therapeutics, therefore, is certainly advancing in the lines which Dr. Ferrand has marked out.

We have already indicated a possible reservation of judgment as to the merits of the book, based upon the excellence with which its details are executed. It was to be expected of a man of Dr. Ferrand's ability that the details would be well done; and such is the case. Of course, there is much to which individual readers will take exception; there is still more which time and increasing knowledge will alter; but, on the whole, the therapeutic precepts of the book, representing as they do the mature opinions of one of the most accomplished writers.
upon the subject, will receive the approval of most of us, and command the respect of all.

A few years ago Fritsch made a good impression by writing an excellent book on obstetric operations. It is since that time that he has attained to his professorship, and all who are familiar with contemporary German work in obstetrics and gynæcology are aware that he has not been idle in the mean time. He must, therefore, have gathered a stock of experience and practical familiarity fitting him to write a more systematic work, like the one now under notice. Critical examination will convince any competent reader, we think, that the book justifies the expectations fairly deducible from the foregoing considerations. It is, indeed, a thoroughly good one—so good in its substance that we wish it were better in its style. We have not seen the German edition, but we remember that the author's other book, to which we referred in the opening sentence of this notice, contained a great many puzzling abbreviations and colloquialisms, so that we can not hold the translator wholly answerable for the obscurities and the solecisms that will vex the reader of this volume; but we do blame him for having made his translation too literal and for having allowed a number of Germanisms to mar his rendering. In some instances, too, he seems to have failed to give the author's meaning. For example, on page 215 we read that the Hodge pessary "stretches the vagina, but does not dilate it." Any one conversant with Fritsch's views on the action of the instrument in question would understand at once that he meant to say that it stretched the vagina lengthwise, but did not enlarge its caliber; but a novice could only look upon the two statements as contradictory. It is possible, however, that the author himself was careless in choosing his words.

While on the subject of style, we may as well speak of the illustrations. Some of them are excellent, but many of them are lacking in clearness of outline. We infer that most of them have been copied from the originals by the photographic process. This does well enough as a general thing, and in most instances a publisher is perfectly justified in saving expense by such a device; but the line ought to be drawn somewhere, and we object decidedly to a reproduction that gives us German words instead of English, as in Fig. 119 (page 209), where for bladder we read Blase!

The author's ideas of the topographical anatomy of the pelvic contents are to a great extent those held by Schultz, of Jenh, and we believe them to be correct in the main, although we can not admit that the uterus is normally in such a decided state of anteflexion as Fritsch and Schultz teach. In one particular a gross misstatement is made—so gross, indeed, that it must be a mere slip of the pen. We refer to this assertion (page 11): "In the recumbent woman the vagina lies almost horizontally." The fact is that, in that posture, its direction is almost vertical, being nearly horizontal when the woman is standing.

That portion of the work that is devoted to the so-called "displacements" of the uterus is admirable, all the more so for being strikingly at variance with the writings of nearly all authors. Since the mechanical conditions involved are so simple and so obvious, it is a marvel that most gynæcologists are so hopelessly in error concerning them. It can proceed only from lack of original investigation, the place of which has been usurped by too ready an acceptance of the plausible but really unfounded doctrines handed down from one writer to another. The limits of our space will not allow us to go into details, but we may illustrate the difference between the views held by the few authors of which Fritsch is one and those that generally pass current by remarking that the former never fall into the disgraceful blunder of attributing a lever-like action to the Hodge pessary. They know that all it can possibly do is to carry the posterior wall of the vagina upward and backward, dragging the cervix in the same direction, and thus cause the body of the organ to drop forward.

We are glad to find that Professor Fritsch inculcates a proper spirit of tenderness in dealing with patients, both as to the matter of inlicting bodily pain and in regard to the duty of sparing their feelings as much as possible—considerations which we are sorry to say, do not often seem to be taken into account by Continental writers. We are pleased to observe, too, that he shows a fair appreciation of the work done by American gynæcologists.

In one respect, however, he has fallen into an error of statement. Speaking of the use of Bozeman's speculum with the patient lying on her back, he says: "Although the inventor applies it with the screw below, I have found it more advantageous to reverse the speculum." The fact is, that Dr. Bozeman uses his instrument with the screw directed toward the pubic symphysis, as Fritsch prefers.

We are surprised to find that the subject of laceration of the cervix uteri is not considered in the book. Whatever the author's opinion may be as to its pathological significance, it is certainly a matter that has engaged the attention of gynæcologists all over the world, and one that the author of a text-book ought consequently to include among the subjects discussed.

On the whole, Fritsch's book seems to us likely to make a decided impression, and we consider it as of unquestionable value.

Whatever merit may be attached to stethometry, it is to the author of this book that credit is due for its advocacy. The stethometer which he has devised is either a two-plane or a three-plane instrument, according as it is to register the movements of the chest-wall in the upward and forward directions, or in these plus the outward direction. Except for one who is constantly making examinations of the chest, we should say there was too much machinery about the instrument, and that it was too liable to get out of order, and so record the chest movements inaccurately, where precision is all important. A specialist, of course, would exercise particular care and attention that its lever and cogs and indicators should move with as little friction as possible. For the general practitioner, and indeed for any one who is at all expert in physical diagnosis, we think there is no instrument so sensitive in appreciating the movements of the chest-wall as the hand used in palpation. The author has undoubtedly acquired great expertise in the use of his instrument, hence his opinion of its value. We doubt whether it will ever be considered indispensable either for diagnosis or for prognosis. As to Dr. Ramsome's claim that it enables one to inform a patient of the probable duration of certain chronic pulmonary diseases, we fail to see its power over the ordinary methods, especially since these same chronic diseases are influenced by many fortuitous conditions. Simplicity of method is nowhere more imperative than in the investigation.
and treatment of disease, and it is hard to conceive of anything more simple or more perfect than the common and accepted methods of physical diagnosis.

A ponderous title for so small a book, and yet its brevity is its chief and only merit. It is written in the school-girl's-composition style, but with a freer use of the personal pronoun of the first person than is common in such effusions. The subject is certainly an important one, but it will not be difficult for the laity, for whom the book is written, to realize that something beside deep breathing, or an attempt at deep breathing, will be necessary to cure consumption and the other ills for which this plan is recommended.

A work so well known as this one is, and by so competent a man as Professor Carpenter, needs no commendation. In this edition it will no doubt prove very acceptable. The wood-cuts, although not very well printed, answer the purpose of illustrating the author's meaning well enough.

Books and Pamphlets Received.

Del Gerini ed Organismi Inferiori contenuti dalle Terre Malariache e Comuni. Ricerche Sperimentali del Dott. Antonio Cenci, Professor d'Anatomia Patologica e Clinica Chirurgica all' Universita di Camerino. (Dall' Istituto Patologico di Praga,) Roma, 1882. 4to, pp. 118.

The Pharmacopoeia of the Northeastern Hospital for Children. Compiled by a Committee of the Staff. London: J. & A. Churchill, 1883. 12mo, pp. 32. [Interleaved.]

Medical Society of the State of Tennessee. Transactions, 1883.

Twelfth Annual Announcement of the Southern Medical College, Atlanta, Ga.

Report on Diseases of Women, etc. By R. J. Nunn, M. D., Savannah, Ga. [Reprint from the "Transactions of the Medical Association of Georgia."]

Transactions of the Medical Society of the State of Pennsylvania at its Thirty-fourth Annual Session, held at Norristown, May 9, 10, 11, 1883. Vol. XV. Philadelphia, 1883.

Report of the Board of Health of the State of Louisiana to the General Assembly, for the year 1882 and the first six months of 1883, embracing the Quarantine and Sanitary Operations of the Board of Health during a Period of Eighteen Months, January 1, 1882, to July 1, 1883. Baton Rouge, 1883.

Answer of Thad. M. Stevens, M. D., to Charges of the Indiana State Board of Health, together with Statements in Proof and Other Matters. Indianapolis, 1883. [Reprint from the "Transactions of the Indiana State Medical Society."]

Remarks on Hydrophobia. By Charles W. Dullea, M. D., etc. [Reprint from the "Philadelphia Medical Times."]

The Hygiene of Exposure, being the Address in Hygiene delivered at the thirty-fourth annual meeting of the Medical Society of the State of Pennsylvania. By Henry Leffmann, M. D., etc. [Reprint from the "Transactions."]

On Shock. By Wm. H. Meyers, M. D., Fort Wayne. [Reprint from the "Transactions of the Indiana State Medical Society."]

A Tracheotomy Tube for Gradual Withdrawal, and Report of a Case in which it was used. By H. F. Hendrix, M. D., of St. Louis. [Reprint from the "St. Louis Medical and Surgical Journal."]

Massage: its Application; and a new Operating Table. By Franklin H. Martin, M. D., etc. [Reprint from the "Chicago Medical Journal and Examiner."]

Report, for the year 1882-1883, of H. A. Newton, Director, to the Board of Managers of the Observatory in Yale College, presented by them to the President and Fellows; to which is appended the Report of the Astronomer in charge of the Horological and Thermometric Bureaus.

A Report on Laceration of the Cervix Uteri. By T. B. Harvey, M. D., etc.

THOMSONISM IN A NEW DRESS.

It is not often that the annual announcement of a medical college shows any noteworthy deviation from the prosaic, but it must be said of the announcement of the "Physio-medical College of Indiana" that it is a singularly amusing document. From it, or rather from an address appended to it, which was delivered before the "Physio-medical Association of Indiana" last May, by a member of the faculty, we learn that physio-medicalism is "Thomsonism cultivated, improved, and advanced"—that is, it is refined gold gilded, a painted lily, to judge from the picture the same address gives of Thomsonism pure and simple. The author of the address does not leave us with this bald definition, however, but goes on to amplify it. Physio-medicalism, he says, is "medicine in harmony with all the functions of life. It is medicine in harmony with vitality itself and with all the structures of the body, with the blood and all the bioplasms." Now, the author of the address, who is no less a personage than the professor of botany, materia medica, and therapeutics, has not merely heard somebody speak the word bioplasms, but he must have seen it in print, for he actually spells it right. Fancy medicine in harmony with all the bioplasms! Not a single atom of bioplasm dissent.

We thought we knew what Thomsonism was, or had been, and we suppose that after all this we ought to have a tolerably clear idea of what physio-medicalism is. Perhaps the reason we have not is that our knowledge of "all the bioplasms" is defective. Bioplasms is one of the words that are good to use when the object is to inspire respect, and it matters little that one knows nothing about the thing itself, for nobody knows enough about it to convict him of any glaring ignorance. But the world has a way of estimating the hidden part of a man's character by what it has been able to observe of the other part, and when such lofty terms are ventured upon it is well to use common expressions as they are used by men of sense. We can not say that the professor has thoroughly guarded himself in this respect, for he gives his readers to understand that in Thomson's time the "regular doctors blistered and bled and poisoned and famished their patients," but that, under all these accumulating horrors, they did not all die, but "many who survived were maimed and injured for life."

But we must turn away from the address, and direct our attention to the college, the institution in which, the professor tells us, covers the usual curriculum "from a physio-medical standpoint," "with specialties enough to fill all the chinks," and "they have all the modern improvements in every direction," he adds—including "water laid on," if we may judge from some doggerel attributed to Thomson. The college no longer has a dean. In point of fact, the faculty "has always ruled the business," and it now proclaims that to have a dean is "a very improper state of affairs in this age of independent thought and action." The last incumbent of the office, feeling that he was "only a human being," and knowing that some physio-medical colleges had "been ruined by the deans exercising the power vested in them by virtue of the title," magnanimously abdicated, and now humbly does duty as a clerk.

Notwithstanding the perfection that appertains to everything connected with the college, it was not until last year, the tenth of its existence, that the faculty discovered the fact that the prevention of disease was of importance, as well as its cure. This fact they deduced from the "satisfaction" given by one M. Veenboer, M. D., of Michigan, who gave a few lectures on sanitary science last year. If the faculty were not thoroughly persuaded that it is worth while to try to prevent disease, we might suggest a suspension of judgment, for, surely, little if anything is to be gained by avoiding an occasion to subject one's self to so delightful a course of medication as the one that is in harmony with "all the bioplasms."

Although we have exceeded the space that we could afford to devote to revealing the beauties of this pamphlet, we have by no means alluded to a great proportion of them. Indeed, the production fairly glitters with gems, being almost as sparkling as "English as She is Spoke." With all their literary accomplishments, however, we fear the "physio-medicalists" are, after all, nothing but the "herb doctors" of bygone years.

OUR ETIQUETTE FROM A CANADIAN POINT OF VIEW.

Last week we alluded to certain matters of taste, that had been twisted into matters of ethics, concerning the professional cards of some physicians in Missouri. But the society before which these vital affairs came up condemned the alleged offenses, not on the ground that they were costumbres del pais, but for the reason that they were committed "several years ago." The cards in question, our readers may remember, were quite remarkable, but perhaps, on the whole, not much more so than one we have lately seen setting forth the qualifications, etc., of a practitioner in Montreal. Suppressing the gentleman's name, together with some other features that might lead to his identification, the card reads as follows:

______, M. D.,
physician, surgeon,
______, street, Montreal.

Graduate in Medicine 1863, _______ University.
Licentiate 1863, Member 1868, College of ______, L. C.
Member 1869, College of ______, Ontario.
Member 1881, _______ Association, England.
Member, _______ Society, Montreal.
Senior ______, Board of Health, Montreal.
Director Canadian ______ Institute.

Treats Specially:

Nervous Disorders in both Sexes, Nerve Exhaustion, Instability, and Diseases of Women and Children.

Noteworthy as this card is in itself, it becomes positively startling in connection with the purpose for which it was sent
to New York. The gentleman whose titles and far-reaching specialties it blazons has not been successful in making as much money by practicing in Canada as he would have liked to make. This failure he attributes not to any shortcomings of his own, but to the narrow notions of ethics that obtain in Canada, whereby men are forced to eschew various means of acquainting the public with their capabilities, and have simply to wait for the public to find them out for itself. This does not suit our Canadian friend. He 'pines for a land of greater liberty. He has evidently pictured to himself the style in which he might bloom out in the United States, and the picture has proved so attractive to him that he has been moved to broach his fondest aspirations in a letter to one of our leading physicians, in which letter the foregoing considerations are set forth. Although he yearns particularly for New York, he adds that he has no objection to Baltimore or Washington. He is willing to serve as an assistant to some eminent practitioner, confident, no doubt, of his ability sooner or later to outshine his principal. All he wants is "a chance."

Now, we do not entertain the supposition that the style of man this many-titled practitioner seems to be is at all representative of our brethren in Canada, for, from all we know of them, they are far too sensible and manly to use reduced show-bills for cards and then whine about being kept down by the prevailing squamishness in matters of ethics. Probably the practitioner in question has already alienated his Montreal brethren by his vulgar and ostentatious display of titles and qualifications, and so deprived himself of that countenance of his peers that should be the first step to his success, for certainly, if such a card is tolerated, what he considers narrow in his countrymen is broad to the verge of infinity in comparison with what he would encounter in New York. Probably nowhere in the world is a display of medical titles more relentlessly tabooed than in the older communities of the United States. We are compelled, therefore, to advise our unhappy Canadian to give up his dream of American license, and we doubt not he would do well to shorten sail somewhat in his own city.

THE AMERICAN DERMATOLOGICAL ASSOCIATION.

With perhaps the single exception of gynecology, the study of diseases of the skin is doubtless the branch of medicine in which the most telling work has been done in this country during the last few years. We have before expressed ourselves to this effect. The New York Dermatological Society has steadily furthered this progress during the period of about fifteen years for which it has existed. Its influence in this direction still goes on. Its usefulness, however, is almost restricted to the individuals who make up its membership, reaching the profession at large in scarcely any other way than by making its members better teachers of dermatology than they would be without it, and so indirectly endowing the young men who graduate from the New York schools with solid acquirements in this branch of medicine. This limitation of the society's sphere of action is largely due to the great preponderance of the clinical element in its proceedings. Certainly, it accomplishes its peculiar work so well that no one conversant with the specialty could wish for any change in its plan, unless indeed it were our only organization devoted to dermatology. As things are, it is most admirably supplemented by the American Dermatological Association, the proceedings of which consist of formal papers and the discussions called forth upon them.

Our readers will see, from the account we give elsewhere in this issue of the association's seventh annual meeting, that that occasion was no exception to the successful meetings that have made up the history of the organization. On the contrary, we are inclined to think that this year's meeting may well be considered one of the most satisfactory that have ever been held, whether we take into account the representative character of the gentlemen in attendance or the number, the variety, and the intrinsic worth of the papers they presented. The practical element was well brought out in Dr. Piffard's paper on the "Treatment of Acne," Dr. Duhring's paper on the "Sulphide of Zinc in the Treatment of Lupus Erythematosus," and Dr. Van Harlingen's narrative of "Experiments in the Use of Napthol," while the other papers dealt with matters of very great pathological interest.

The discussions show a substantial agreement on important points that tend to mark the progress of dermatology toward the comparatively finished state of the leading departments of medicine. Yet enough diversity of views was manifested to show that that state has not yet been reached, but that original thought abounds sufficiently to prevent stagnation. It is interesting to note, on the one hand, the real accord on the subjects presented by Dr. Taylor, Dr. Hyde, and Dr. Stelwagon, and, on the other hand, the success met with by Dr. Graham, Dr. Sherwell, and Dr. Fox in bringing up matters that call for further study. The other contributions were mainly of a clinical nature, but they were nevertheless such as could fairly be brought to the attention of an assembly of this sort. On the whole, the practical seems to have been judiciously interspersed with the theoretical, and both appear to have met with careful consideration. If the success of this meeting may be taken as a test, the association certainly did well to re-elect Dr. Taylor to the presidency.

MINOR PARAGRAPHS.

THE GARFIELD MEMORIAL HOSPITAL.

The statement having lately been made that the plan of establishing the hospital had been abandoned for lack of support, we are glad to learn, on the authority of a member of the hospital board, that the report is untrue. A piece of property has been obtained at the head of Tenth Street, in Washington, on which there is a brick building which, it is thought, can be made available for hospital purposes by some alterations and additions. The latter are to be carried out under the superintendence of Surgeon J. S. Billings, of the army.

THE CINCINNATI BOARD OF HEALTH.

The solitary medical member of Cincinnati's disreputable board of health, Dr. J. C. Beck, seems to have turned upon his critics, having caused warrants to be issued for the arrest of two persons connected with a newspaper called the "Penny
Post," on a charge of criminal libel. The paper had published statements to the effect that Dr. Beck had made appointments for a money consideration.

A NEW BUILDING FOR THE HEALTH DEPARTMENT.

It is understood that the President of the Board of Health is preparing an application to the Board of Estimate and Appropriation for funds with which to provide a new building for the use of the Health Department. Heretofore the department has occupied a portion of the Police Department's building. In view of the increasing bulk and the valuable nature of the records kept by the Bureau of Vital Statistics, and of the increasing duties of the department in general, there can be no doubt that a new building will be found to be positively necessary before many years.

A SUGGESTION TO THE SOCIETY FOR THE PREVENTION OF CRUELTY TO CHILDREN.

The casual wayfarer in any of our city parks can scarcely have failed to be struck at times, and altogether too often, with the brutality exercised by nurses toward the little children entrusted to their care, toppling them over and dragging them about as if they were legitimate objects on which to vent their annoyance. To say nothing of the bad effect such treatment must often have upon the moral nature of an observant and inquisitive child, there can be no doubt that serious and lasting physical injuries are often the result. There is abundant reason to believe that the most prolific source of lip disease, and certain affections of the spine, is injury inflicted in some way or another, and very often of a degree so slight as to escape the attention of those who are not aware of the facts in regard to such cases. If the Society for the Prevention of Cruelty to Children would take the matter in hand, and detail one of its officers to each of the parks, we are confident that much good would be effected.

CHICAGO LARD.

"In the course of a dispute between Chicago dealers in lard," said the "Boston Medical and Surgical Journal" for August 24, "it has been incidentally disclosed that most American lard is adulterated from ten to one hundred per cent, with oleomargarine, stearine, cotton-seed oil, tallow, and terra alba." Replying to this sweeping allegation, the "Weekly Medical Review," of Chicago and St. Louis, states that evidence will shortly be published concerning the matter, and that it will not be found to justify the imputation.

A NEW MEXICAN JOURNAL.

Both in Spain and in Central America many new medical journals have sprung up during the last few months. The newest one we have seen is the "Revista Medico-quirurgica de Mexico," published three times a month, each number containing ten large double-columned pages. The first number, dated August 10, 1883, contains an article on amputation of the leg at the point of election, illustrated with some very creditable cuts, together with several abstracts and news items. The "Revista" is owned and edited by Dr. V. Blay, Dr. T. Noriega, and Dr. J. Robles.

A CHARITABLE BEQUEST NULLIFIED.

A lady died some time since in Chicago, leaving all her property to her mother on the condition that she made a will leaving all that might be unspent at her death to some Chicago institution for the benefit of women. The mother refused to take the property subject to this condition, and maintained that by such a refusal the daughter practically became intestate and the property would come to her as heir at law without any restrictions. The Woman's Hospital of the State of Illinois and the Chicago Hospital for Women and Children did not take this view, but each asserted that it was a suitable institution to take the property under the will, and that the evident charitable intention of the testatrix could not be defeated in this indirect manner. The Court held, however, that neither of the hospitals could have an interest unless the mother made her will in their favor; that, as she refused to do this, there was no way of compelling her to such a course, and that their claims must be dismissed. The clear and strong desire of the daughter to benefit her sex by a large bequest was thus absolutely frustrated.

NEWS ITEMS.

INFECTIOUS DISEASES IN NEW YORK.—We are indebted to the Sanitary Bureau of the Health Department for the following statement of cases and deaths reported during the two weeks ending September 4, 1883:

<table>
<thead>
<tr>
<th>Week ending Aug. 28</th>
<th>Week ending Sept. 4</th>
</tr>

YELLOW FEVER.—On Thursday of last week three new cases were reported from the Pensacola Navy-Yard. The same day the board of health of the town passed resolutions declaring that there was no longer any reason for neighboring towns to maintain a quarantine against Pensacola, and authorizing the president of the board to represent the fact to those towns, and ask that the quarantine be raised. On the same day the Surgeon-General of the Marine-Hospital Service received official information from Ship Island that there were twelve vessels in quarantine there, from which nineteen yellow-fever patients had been taken, all from Vera Cruz.

On Friday no new cases were reported from the Pensacola Navy-Yard, and there were no deaths there.

On Saturday one Dr. Basso, who had presented himself at Pensacola for the purpose of curing yellow fever with a nostrum, was attacked with the disease, and died on Monday.

Up to midday on Tuesday no new cases had been reported.

THE CHOLERA has continued to decrease steadily during the week in Egypt, and the epidemic is now thought to be nearly at an end. A supposed case was reported from Milwaukee last week, but opinions were divided as to its real nature, and, as no further report has reached us from that quarter, it seems probable that the disease was not true Asiatic cholera.

INFECTIOUS DISEASES OF DOMESTIC ANIMALS.—The Texas cattle fever is reported to have broken out in Detroit, anthrax is said to be raging in the country about Lancaster, Pa., and a disease of an uncertain nature caused the death of thirteen cows on one farm near Newburg, N. Y., during the last week in August, the course of the disease being not longer than twelve hours in each instance. A hundred more Canadian cattle were reported on Thursday of last week to have been slaughtered at Liverpool, as they were suspected of being infected with disease. The remaining cattle of the same shipment were released and sent to various markets.

THE EIGHTH ANNUAL MEETING OF THE AMERICAN GYNECOLOGICAL SOCIETY will be held in Philadelphia, at the Hall of the College of Physicians, on Tuesday, Wednesday, and Thursday,
September 18th, 19th, and 20th. Papers are expected to be read as follows: “Superinversion of the Uterus,” by Dr. Joseph Taber Johnson, of Washington; “The Importance of Cleanliness in Surgical Operations,” by Dr. Z. Stansbury Sutton, of Pittsburg, Pa.; “Some Points Connected with the Subject of Dysmenorrhea,” by Dr. C. D. Palmer, of Cincinnati; “An Unusual Form of Abdominal Tumor—three cases,” by Dr. Thaddeus A. Reamy, of Cincinnati; “Is Extirpation of the Cancerous Uterus a Justifiable Operation?” by Dr. A. Reeves Jackson, of Chicago; “A Biographical Sketch of Dr. Nathan Smith, Founder of the Dartmouth Medical College” (being the President’s address), by Dr. Gilman Kimball, of Lowell, Mass.; “The Management of Accidental Percutaneous and Other Injuries of the Gravid Uterus as a Complication of Laparotomy,” by Dr. Charles Carroll Lee, of New York; “A New Method of Operating for Fistula in Ano,” by Dr. Edward W. Jenks, of Chicago; “Ergot: the Use and Abuse of this Dangerous Remedy,” by Dr. George J. Engelmann, of St. Louis; “Congenital Fissure of the Female Urethra with Extrophy of the Bladder,” and “Menstruation after Extirpation of the Ovaries,” by Dr. Henry F. Campbell, of Augusta, Ga.; “Remarks on Chronic Abscess of the Pelvis,” by Dr. William H. Ryford, of Chicago. A discussion on Death after Labor will be opened by Dr. Campbell.

The Pennsylvania and Maryland Union Medical Association, composed of representatives from the medical societies of the counties of Franklin, York, Lancaster, Chester, Lebanon, Cumberland, Perry, and Dauphin, in Pennsylvania, and Harford and Cecil, in Maryland, held its sixth annual meeting at a place near Chambersburg, Pa., on the 30th of August, Dr. W. W. Dale, of Carlisle, Pa., in the chair. Dr. J. L. Zeigler, of Mount Joy, was elected president for the coming year; Dr. S. B. Keefer, of Carlisle, and Dr. John Lineaweaver, of Columbus, vice-presidents; and Dr. S. J. Rouse, of York, secretary and treasurer.

The Hay Fever Association.—At the tenth annual meeting of the United States Hay Fever Association, held recently at Bethlehem, N. H., a vote was taken on the merits of “Townsend’s remedy.” Ten of the members had used it, but not one had found it of service.

The Medico-Legal Society.—At the meeting to be held on Wednesday evening of next week, Dr. R. L. Parsons will read a paper entitled “Jury Trial of the Insane.”

The cultivation of Cinchona in South America.—Extensive preparations are said to be in progress for experiments in the cultivation of the cinchona tree in South America and Mexico, including the selection of sites for planting 5,000,000 trees.

The Indiana State Board of Health is meeting with criticism for alleged inefficiency, due, it is said, to its having embarked in political intrigues. Its secretary, Dr. E. R. Hawn, who was appointed after Dr. Thaddeus M. Stevens was deposed, has lately died, and the board was to meet on Thursday to choose his successor.

The German Universities.—The following changes have been made in addition to those we have before recorded: At Vienna, Professor Nothnagel’s assistant, Dr. Jaksh, has been made a Privat-Dozent in medicine; Professor Schwabale, of Königsberg, succeeds Professor Waldeyer at Strassburg as professor of anatomy; Dr. Fischer, a Privat-Dozent, has been appointed extraordinary professor of surgery at Strassburg; and Professor E. Baumann goes from Freiburg to Breslau as ordinary professor of physiology.

St. Joseph’s Hospital, in Lancaster, Pa., having been sold at sheriff’s sale, has been bought by the Sisters of St. Francis, of Philadelphia, who, it is announced, will make it a free hospital.

Cremation proposed in New Orleans.—It was reported from New Orleans last week that the Grand Jury had suggested the establishment of a crematory, under the direction of the authorities of Charity Hospital, for the purpose of incinerating the bodies of persons dead of infectious diseases.

An Asylum Assault Case in Philadelphia.—A keeper in the lunatic department of the Philadelphia Almshouse was suspended from duty last Saturday for having struck one of the patients. Maintaining that he had done this in self-defense, he was told by the superintendent that, when attacked by a patient, he should run and call for assistants to help control the man without hurting him, to which he replied, shaking his head defiantly, “I’ll never run.”

The Hunter Alleged Malpractice Case, an outline of which we gave two weeks ago, is likely, as we then hinted, to turn out a creation of Dr. Hunter’s imagination, for he has since committed suicide, and a natural inference is that he was insane at the time of Mrs. Hunter’s death.

Dr. Joseph C. Hutchinson, of Brooklyn, our readers will regret to learn, met with a serious injury last week while driving at Lake George. He was thrown from the carriage, and sustained a fracture of the thigh. He has been taken to his home in Brooklyn, and we are glad to be able to say that the reports give promise of his prompt recovery.

Notable death of a London practitioner.—Dr. James Dowling Trask, M. D., of Astoria, N. Y.—Dr. Trask died on Sunday, the 2d inst., after a short illness. He was born in Beverly, Mass., in 1821, was graduated in Arts at Amherst College in 1839, and received his medical degree from the Medical Department of the University of the City of New York in 1844. He began practice in Brooklyn, then removed to White Plains, and finally, in 1839, settled in Astoria. He was at one time professor of obstetrics and diseases of women and children in the Long Island College Hospital, and was one of the founders of the American Gynæcological Society, of which he was last year a member of the council. He was highly esteemed as a practitioner, and his memory will be perpetuated by several important contributions made by him to the literature of obstetrics, especially by an article on the use of iodine in the treatment of post-partum haemorrhage.

Charles Wright, M. D.—On Sunday, the 2d inst., Dr. Wright, a resident of New York, died in London. He was a graduate of the Medical Department of the University of the City of New York, class of 1853, and a member of the Medical Society of the County of New York, the Academy of Medicine, the Medico-Legal Society, and the Society for the Relief of the Widows and Orphans of Medical Men.

Edward F. Barnes, M. D., of Claremont, N. H.—Dr. Barnes died on Tuesday, August 28th, at the age of thirty-three. He was born in Claremont, November 2, 1850, and received his education in the Stevens High School in that place, graduating from it with high honors in 1871. In 1877 he was graduated from Bellevue Hospital Medical College, and, after a short stay in Decatur, Ill., he settled in his native town, where he remained until his death. The Claremont Medical Association, of which he was a member, has passed suitable resolutions.

Marjorie, of Brittany.—The death of this eminent surgeon is announced to have taken place recently, as the result of septicemia following a punctured wound inflicted during an operation on a hospital patient.
Procedures of Societies.

AMERICAN DERMATOLOGICAL ASSOCIATION.

The seventh annual meeting was held at Lake George, N. Y., August 29, 30, and 31, 1883.

First Day.—Morning Session.

The meeting was held at the Sagamore House, and the association was called to order at 10:30 o’clock by the President, Dr. H. W. Taylor, of New York, who welcomed the members with a few appropriate remarks.

The Treatment of Acne.—Dr. H. G. Piffard, of New York, read a paper on this subject; the term acne was restricted to inflammation of the sebaceous glands. This affection never began, and relapses never occurred, without sufficient cause, and the first indication was to seek for, and, if possible, remove the etiological factor; whether gastric, intestinal, uterine, or the like, it was only partly true that acne was an incurable disease. It was apt to relapse, but could be cured for the time being quite easily. Its course might often be shortened. Dr. Piffard then related the case of a patient with ovarian trouble, the removal of which was followed by a cure of the acne. He also referred to a case of chronic incurable organic uterine disease in which a severe acne existed that persisted despite treatment, and stated that in such instances all that could be reasonably expected was temporary alleviation.

Acute Acne Vulgaris.—The drug which he had administered internally with the most satisfactory results was the calx sulphurea, in small doses, to be discontinued as soon as good results were manifest. Next in efficacy was the bromide of arsenic in doses of 1/10 to 1/5 of a gram; a one-per-cent. alcoholic solution administered in doses of from one to two minims (not drops) in a wineglassful of water upon an empty stomach. As the acne improved, he lessened the doses. He had found the former drug most serviceable in the lymphatic variety, and the latter in acne of the florid type. For external treatment he used dilation by incision, and bathing with warm (not hot) water. In simple cases he punctured the papules, and punctured each fresh pimple as it appeared. The next external application recommended was frequent bathing with very hot water. In the purulent variety the pustules should be punctured, the contents squeezed out, and the parts bathed with hot water to reduce the congestion. Other external applications mentioned were soothing agents, such as belladonna and stramonium; belladonna liniment mixed with benzoinated lard, sometimes with ammoniated mercury; and fluid extract of stramonium, made from the fresh leaves gathered in the autumn, incorporated with benzoinated lard in the proportion of one draught to the ounce.

Subacute Acne Vulgaris.—Calx sulphurata should be used in much larger doses than in the acute form, and continued until the action of the drug is manifested by increased activity of the eruption, perhaps by an increased number of the lesions, and perhaps by a tendency to suppuration. In occasional cases he used mercury (corrosive sublimate), iodide of potassium, or ergot. In the external treatment the principal indication was the employment of applications which produced an irritant or substitutive inflammation, such as green soap, sulphur, biniodide of mercury, and corrosive sublimate, which, acting as irritants, were followed by hyperemia with swelling, etc. When the action had reached a proper limit, the remedy should be stopped and the parts allowed to return to the healthy state. The strength of these applications must be varied according to the effects produced. It was well to begin with applications of moderate strength. The author then referred to the views of the Vienna and French schools, and to the practice of English and American dermatologists. With regard to ergot, as recommended by Dr. Denslow, of New York, given in doses of 20 or 30 grains twice or three times a day, and continued for several weeks, he had seen some cases in which benefit followed.

Comedones.—These yielded only to mechanical treatment. Remove them by pressure upon the surrounding skin, and, if the sebaceous plug does not readily come out, enlarge the mouth of the duct with a fine needle.

Acne indurata, whether acute or subacute, might be regarded as an aggravated acne vulgaris, and the principles of treatment were substantially the same as in acne vulgaris. The most striking results he had seen follow the use of ergot had occurred in this form of the disease.

Dr. I. E. Atkinson, of Baltimore, had used the sulphide of calcium faithfully, but had failed to produce the favorable results which, from time to time, had been reported. He had used ergot, but also without noteworthy benefit. Whatever of benefit he had seen had been from the use of local applications, together with such remedies and measures as were indicated to correct or remove the gastric, intestinal, or uterine disorders which were generally considered to be causes of this local inflammation.

Dr. A. Van Harenberg, of Philadelphia, had used with considerable benefit in several cases of comedones the following, smeared over the elevations: Official acetic acid, two parts, glycerin, three parts, and kaolin, four parts.

Dr. W. T. Alexander, of New York, had used calx sulphurea with considerable benefit, but usually only in the purulent variety. On the other hand, he referred to a case in which the remedy administered in small doses four times a day exhibited lack of power to arrest suppuration. The only good effect he had seen follow the use of ergot was a seeming diminution of the redness, but only so long as the drug was being taken.

Dr. S. Sherwell, of Brooklyn, had not employed the sulphide of calcium. He had obtained sufficiently good results by the use of external applications with the use of internal remedies, especially ergot. He had found cannabis indica of great benefit in acute forms of the disease, tending to the purulent state. He associated acute purulent acne with membranous disturbances very decidedly, and always employed ergot, moderately during the period, more freely between the periods, especially just before and just after the occurrence of one. He could speak with certainty of the beneficial effects produced by the drug in this form of acne in women, and had thought benefit followed its use in men. In the rosaceous form of acne he had found ergot especially beneficial. He regarded its use as empirical, in all probability; at least, he did not accept Dr. Denslow's view that it acted upon the muscular tissue of the skin.

Dr. Graham, of Toronto, had found calx sulphurata useful in suppurative diseases, whether acne or the formation of abscess.

The President said the interest in the paper centered upon the relative importance of local and of constitutional treatment. He wished to record his belief again that a curative influence was exerted only by local measures, and that internal treatment was only subsidiary. As regarded the reciprocal relations between acne and uterine affections, he had not yet reached any definite conclusions. That they existed at the same time in the same patient was well recognized, but he had not yet become satisfied as to whether there was any causal relation between the two conditions. In the treatment of acne he had placed great reliance on alkalies and diuretics; one or two draughts of Rochelle salt with thirty grains of the acetate of
potassium in a wineglassful of water three times a day. In the hyperemic form he always produced benefit by this medication, and also in the indurated variety. Besides puncturing, as recommended by Dr. Piffard, he had been accustomed to apply liquid hydrargyri pernixatis, 1 to 8 of water, once or twice a day. He had also used with marked benefit, both in that and the rosaceous form, half a drachm of chrysarobin to one ounce of flexible collodion, brushed over the patches. The use of the remedy necessitated sequestration of the patient for some time. He had also succeeded in the treatment of acne indurata by the use of Donovan's solution, pushed until ten or twelve drops were taken at a dose, three times a day. In his hands ergot had not cured a single case. It had relieved the hyperemia, but had had no effect upon the induration. In the various forms of acne he had brought out the most gratifying results by the use of mercurial ointment—1 to 8 of vaseline—or an ointment of bismuth of mercury.

Dr. Stelwagon, of Philadelphia, had seen good results from the use of a lotion of sulphate of zinc, one drachm, sulphide of potassium, one drachm, and water, four ounces. The President and Dr. Sheewell had used this lotion with good results. The President had used an ointment of iodide of zinc, 5 to 30 grains to one ounce of vaseline or lard, with excellent results.

General Exfoliative Dermatitis.—Dr. Graham, of Toronto, then read a paper in which he first directed attention to the significance of the term, and then made brief allusion to the literature of the subject. He had collected 34 cases, of which 11 terminated fatally and 10 in recovery, while in 7 the recovery was partial or the result was not known. In 8 cases the disease ran an acute course, not lasting longer than a few weeks, and in 26 it was chronic, lasting for months or years. He had had four cases under observation, two of which were of a chronic character, and two acute and recurrent. In the third case the seizures recurred at various seasons of the year, and in the fourth case the first three took place in summer and the fourth in March. In both, the disease ran a very similar course, except that in the latter there was a vesicular eruption in the beginning. It was probable that many cases of general exfoliative dermatitis had been mistaken for scarlet fever. The principal features of the disease might be considered under three heads: 1. General hyperemia; 2. General exfoliation of the epidermis; and 3. Severe constitutional symptoms appearing at various times throughout the attack, and in many instances a tendency to a fatal result. In some cases there was a serous exudation preceding the hyperemia and exfoliation. From his observations, the author of the paper agreed with Dr. Baxter and Dr. Janieson in the opinion that the term general exfoliative dermatitis might be applied to all the cases which were usually described under the names pityriasis rubra and pemphigus folliciaceous, as well as to other cases which could not be classed with either. There were two principal subdivisions of the affection: 1, the acute; 2, the chronic. Of the latter there were two varieties: 1, that in which hyperemia and exfoliation existed, and it might be called dermatitis exfoliativa rubra; 2, that in which a serous exudation, in the form of bullae, preceded the exfoliation, and this might be called dermatitis bullosa exfoliativa. The former variety would include pityriasis rubra, and the latter pemphigus folliciaceous. The acute form had a strong tendency to recur, influenced by seasons or outward circumstances. The recurrences might be accounted for by individual peculiarities.

Dr. Hardaway, of St. Louis, had had under observation one case of five years' standing, which manifested some improvement under the internal use of the tincture of iron, all other methods of treatment having failed. He had seen one quite acute case, another in an infant, another in a young lady of neurotic family. Since the attack, now six or seven years, the latter had suffered from frequent occurrences of bright hyperemic spots, varying in size from that of a silver dollar to that of the hand, exceedingly hot and throbbing to the touch, and without exfoliation. Dr. Atkinson thought it impossible to describe a distinct disease that could be called pityriasis rubra. Again, it was desirable to find some name to apply to certain cases, and he thought general exfoliative dermatitis was as good as any, perhaps. He believed that there was a very wide range in these cases, but that the disease always depended upon trophic neuroses, the nature of which we did not understand. Some cases answered to pityriasis rubra; others showed patches which were undoubtedly eczematic; and then there were chronic cases of exfoliative dermatitis. He regarded it as important to remember that the skin of certain individuals manifested a marked tendency to become inflamed as the result of the internal use of certain drugs; for example, there was a well-marked eruption produced by quinine.

Dr. G. H. Fox, of New York, approved of what Dr. Atkinson had said concerning the advisability of including all forms of dermatitis under the general name, and thought it was fallacious to endeavor to make a differential diagnosis clinically. As to pityriasis rubra and eczema, however, he believed there were reasons for making a distinction, and in many of the cases of general desquamation which were spoken of as exfoliative dermatitis there was an eczematous process which involved the mucous layer of the skin, and was not a disease of the vascular supply, or a primary disturbance of the nervous system, like pityriasis rubra. He thought Dr. Graham had done well in associating the acute and chronic cases.

Dr. P. A. Monroe, of New York, believed the disease to be neurotic in character, and in two cases he had seen decided benefit produced by arsenic.

Dr. Sheewell thought that an exception should be made with reference to pemphigus folliciaceous, as it was sufficiently distinct in character to be entitled to its original name. He accepted Dr. Graham's first division, but not the second. Dr. Piffard thought there were three affections quite distinct: 1, Pemphigus folliciaceous; 2, pityriasis rubra; and, 3, dermatitis exfoliativa. He admitted that it was sometimes difficult to make a differential diagnosis, but that fact could not be used as an argument in favor of a general name. Dr. Graham said he had doubted the propriety of placing pemphigus folliciaceous under the head of general exfoliative dermatitis; but, at the same time, the two conditions had so many features in common he had ventured to do so.

The President regarded the further study of the three affections mentioned by Dr. Piffard as very important. He then called attention to two cases. The first occurred in a woman thirty years of age, a widow, the mother of one child, and a sufferer from chronic malarial disease, who had had fifteen attacks produced by taking quinine, eichonine, or elixir of cali- saysa. The second case occurred in a man nineteen years of age, who had been under observation five months. The patient had been exhibited to the New York Dermatological Society, and the history, so far as there given, had been published in the July number of the "Journal of Cutaneous and Venercal Diseases." The interest of the case centered in the question whether or not the condition of the skin depended upon syphilis. It was the most remarkable case of exfoliative dermatitis he had ever seen, and was surrounded with grave doubt concerning its etiology.

Dr. Taylor's description of the case was accompanied by several photographic illustrations.

Impetigo Contagiosa.—Dr. Stelwagon, of Philadelphia, in a paper on this affection, first referred to its individual nature,
and the correctness of the views advanced by the late Dr. Tilbury Fox. He believed there was no evidence that the disease was in any way related to ringworm, or that it followed contagious pustular affections, as stated by Dr. Hyde, of Chicago. Further, that a pustular disease could not be modified, or, in a case of any modification could be produced, that the modification could propagate itself. If the disease was not a modification of some other affection, the conclusion must be that it was an independent one, and the individuality of the disease must be admitted. The eruption was contagious. He doubted the view that it was of a fungous nature. In five hundred microscopic examinations he had been unable to find the fungus described by Dr. Piffard except in three instances, and regarded the fungi, when found, as in all probability adventitious. The view that the affection was a systemic disease with cutaneous manifestations seemed to him the most tenable. This was sustained in a measure by the writings of Tilbury Fox, and there were several reasons to support it. Aggregate experience proved the existence of premonitory symptoms, and ordinarily it ran a short but definite course. The eruption was self-incubating, which explained the existence of new patches. There were several facts against the supposition that the disease followed vaccination. The author's conclusions were: 1, That it was a separate and distinct disease; 2, that it was not parasitic; 3, that it was not related to vaccination; and, 4, that it was an acute systemic disease with cutaneous manifestations, and probably due to a specific poison. Dr. Hardaway regarded the fact that the disease occurred epidemically as a strong argument in favor of its being an independent affection.

Dr. Atkinson felt very uncertain concerning the individual nature of the disease. Dr. G. H. Ronk, of Baltimore, did not recollect having seen a case during the last two years. That the pus of impetigo contagiosa was inculcable was quite certain; that it was inculcable upon healthy individuals; and that successive inculcations became weaker. He had been unable to find a fungus. That it was an independent disease he was moderately sure; but that it was found only after contagious diseases, and in individuals who were not in good health, as suggested by Dr. Hyde, he did not believe, yet what the exact nature of the disease was he did not know.

Dr. Fox thought it was agreed that the pus was inculcable; that it did not depend so much upon the character of the soil as on the character of the pus, and that the peculiar pustules were not to be classed as those of pustular eczema. He thought Tilbury Fox was unwise in giving the affection a new name. He had generally studied it as a disease of the skin, but the suggestion that it was constitutional was worthy of attention. Dr. Fox was also inclined to doubt the proposition that it had no connection whatever with vaccination; but exactly what the relation was he was unable to say. With regard to pediculosis, it might not produce an eruption, but certainly it would cause the spread of one.

Dr. Graham had always regarded impetigo contagiosa as a distinct disease, and was inclined to agree with Dr. Stelwagon concerning its nature. Dr. Piffard preferred to go back to the old name. He had had a series of cases in different families, and in every instance the first in each series appeared shortly after vaccination, and the other cases followed. As to its parasitic nature, he was still inclined to hold to that view, although no one had found a definite parasite in the vesicle: fungi had been found in the crusts only, and several who had found fungi had found different ones. He found, at the time he made his observations, a permanent fungus, the same as he found in vaccine, and similar ones had not been described in connection with any other form of disease. If it were a common crust fungus, he would be forced to give up the connection of the disease with vaccination. A point in favor of its parasitic nature was the fact that it was cured so readily with parasiticides. He had not regarded it as a self-limited disease, but thought the explanation given by Dr. Stelwagon was a very ingenious one.

The President was a firm believer in the individuality of the disease. He could not regard it as a systemic affection. The existence of a premonitory fever was exceedingly doubtful. In sixty cases he had observed, the disease began about the face or nails in every instance, and afterward different parts of the body were inoculated. He thought the systemic reaction could be easily explained by the existence of an eruption. He believed it spread by immediate contagion; also that the disease originated in some form of pus which lodged upon the skin, and developed a pustule, from which it was communicated to others, or to other parts of the body.

Dr. Fox had had cases which did not yield readily to treatment, and had remained obstinate for two or more weeks.

Dr. Stelwagon said that sometimes several weeks were required to get rid of the disease.

Dr. Ronk did not wish to indorse the view that the disease was systemic in the same sense as scarlet fever, etc., but simply wished to say that he regarded it as inculcable locally.

Dr. Hardaway had not seen the disease associated with vaccination.

Evening Session.

The association was called to order at 8 o'clock, the President acting as chairman. The President reported two cases seen with Dr. W. H. Draper at the clinic at the College of Physicians and Surgeons. The first was that of a puny child, six months old, that had an ulcer upon the back which began as a water-blister. Despite treatment, it extended and became very large, destroying the skin down to the muscles. Under generous diet and tonics it ultimately recovered. The other case occurred in a woman thirty years of age, married, who had never had children, and had never taken ergot. She came with each finger on both hands in a bluish congested condition, but no bulla existed. There was swelling of the tip of the nose, and upon it was a bulla, which broke down into an ulcer, involving all of the tissues down to the cartilages. The patient lost fully one half of every finger, the thumbs escaping. She finally recovered. The only etiological factor that could be ascertained was excessive indulgence in buckwheat cakes.

Experiments in the Use of Naphtol.—Dr. Van Harlingen read a paper in which he gave the conclusions reached by Kaposi, who introduced the use of the remedy, with a summary of his personal experience in its use. He had found it of great
service in scabies, also of some value in the treatment of psoriasis. In parasitic skin diseases it was of but little use, while in eczema and hyperidrosis it was entirely without value.

Dr. Fox had used the remedy externally in almost every case where he could possibly employ it, and had become convinced that it fell far short of taking the place of tar. In a few cases of eczema of the scrotum and anus he had obtained very satisfactory results from the application of a five-per-cent. ointment. For psoriasis of the scalp and face the ordinary white precipitate ointment had served more satisfactorily.

Dr. Wigglesworth, of Boston, thought Kaposi did not use naphthol so much as formerly. His own experience corroborated that of Dr. Fox.

Dr. Hardaway had found it very much inferior to chrysophanic acid in psoriasis and eczema. In the fissured and squamous eczema of the palms of the hands and fingers he had used a fifteen-per-cent. ointment with good success.

Dr. Stelwaggon thought it inferior to white-precipitate ointment for psoriasis of the scalp, regarded it as very efficient for scabies, and was of the opinion that it was now scarcely used in Vienna except in the treatment of this affection.

Dr. Piffard regarded naphthol as a dangerous remedy. The President had used it with good results in scabies, but in psoriasis it had proved inefficient.

LEPROSY IN NEW BRUNSWICK.—Dr. Fox then read a communication entitled "A Trip to Tracadie," which contained joint propositions submitted by himself and Dr. Graham, of Toronto. Tracadie had a lazaretto where lepers resided. During this summer he had visited the place, and so also had Dr. Graham, under the direction of the Dominion Government. The lazaretto had at present 24 inmates, 11 males and 13 females, and was under the charge of sisters of charity. The disease as seen was partly of the tubercular and partly of the macular variety, and there were three cases which were not leprosy.

Some of the cases showed a peculiar skin disease that appeared to be syphilitic in character, although there were no marked lesions of syphilis. As to the white scales so often referred to, he was struck with the fact that both forms showed shining silvery scales, very much like those found in psoriasis, but not having the peculiar circumscribed form. Many of these patients had papular eczema, which gave them much annoyance. Most of those, with the tubercular form especially, presented marked ulcerations of the hard palate; in one case there was perforation.

Many of the patients presented a well marked form of dactyliitis, without the suspicion of syphilis, but with enlargement of the bones of the toes in one case. Those who had ulceration of the hard palate had also laryngeal trouble; either the peculiar wheezing or complete aphonia. The following propositions were submitted by Dr. Fox and Dr. Graham:

1. Leprosy is a constitutional disease, and in certain cases appears to be hereditary.
2. It is undoubtedly contagious by inoculation.
3. There is no reason for believing that it is transmitted in any other way.
4. Under certain conditions a person may have leprosy and run no risk of transmitting the disease.
5. It is not so liable to be transmitted to others as syphilis is in its early stages. There is no relation between the two diseases.
6. Leprosy is usually a fatal disease, its average duration being from ten to fifteen years.
7. In rare instances there is a tendency to recovery after the disease has existed many years.
8. There is no valid reason for pronouncing the disease incurable.
9. Judicious treatment improves the condition of the patient, and often causes a temporary disappearance of the symptoms.
10. There is ground for the hope that an improved method of treatment will in time effect the cure of leprosy, or at least that it will correct and control the disease.

Dr. Fox admitted that he had yet to cure his first patient, but he did not believe that leprosy was incurable. The treatment adopted in the New York hospitals, consisting in the use of chaulmoogra oil and large doses of nux vomica, had afforded a degree of success, and he read a letter which showed that the disease in one case had at least been non-progressive for some time. There was no evidence that either physicians or nurses had acquired the disease by attendance upon those affected with it.

Dr. D. B. Simmons, who had had a large experience in the treatment of this disease in Japan, was invited to open the discussion. He thought it exceedingly difficult to study leprosy in lazarettos. According to his observation, and the view was fully recognized by the Japanese, the disease manifested itself first in the face, and by a peculiar blushing or lividity of the features, especially after taking wine, etc. The development of this peculiar appearance was sufficient to drive the person immediately into exile. Next the anesthetic symptoms, usually, are most prominent—anesthetic spots with any other manifest change in the condition of the skin or the existence of other symptoms. Then the disease showed itself upon the ears or elsewhere, with exacerbations at times, sometimes with fever, bleeding from the nose, etc. His own opinion was that it was decidedly hereditary, but it was exceedingly difficult to reach facts bearing upon this question, because of the prompt exit of any member of a family who developed the first peculiar symptoms, and the subsequent denial that the disease ever existed in the family. He did not regard it as either contagious or infectious, and it was not regarded by the Japanese as contagious. The duration of the disease was exceedingly variable. He had never succeeded in curing a case, nor had he seen a case which had been cured, but almost without exception every case might be benefited by treatment. Strict attention to hygiene, diet, and cleanliness, aided by the internal and external use of copalba, had yielded the most favorable results he had obtained.

Dr. Roux said, if the disease was spread by contagion there was a marked difference in the susceptibility of different persons to its influence; a much more marked difference than existed with reference to any other contagious disease.

Dr. Wigglesworth had studied the disease in Norway and Spain, as well as in the East, and could corroborate Dr. Fox’s views concerning the non-communication of the affection to physicians and nurses. His view was that, while it was inoculable it is but faintly, if at all, contagious, and not at all infective. Nor did he see any thing in the detection of white patches to suggest the existence of the disease.

Dr. Graham regarded the disease as inoculable and infective. He was also inclined to believe that it was hereditary, although no case in Tracadie had confirmed that impression. He had noted a decidedly marked difference in the susceptibility of different persons, as illustrated by one family especially in Tracadie.

Dr. Piffard accepted the ten propositions. He also referred to one instance in which a physician took the disease and died of it. He thought it was utterly impossible to determine in any given case whether the disease was due to heredity or to infection.

Paget’s Disease, or Malignant Papillary Desmatoes.—Dr. Sherwell then read a paper on this subject. He had had two cases, and these, with those recorded by Paget, Butlin, Morris, Thin, and Duhring, made twenty-seven. He had recorded
his first case, the first published in the United States, in the January number of the "Journal of Cutaneous and Venereal Diseases." He gave the following conclusions:

1. The subjective symptoms, itching, burning, are those of an eczema, and not those of an ordinary cutaneous affection, but they are more marked than in ordinary cases of eczema.

2. The objective symptoms are like those of eczema; the discharge is absolutely similar; it stiftens lignen, and forms crusts entirely indistinguishable from those of an impetiginous eczema. The color of the surface is perhaps occasionally more livid, but the border is not more sharply defined than is common in that trouble. The somewhat elevated appearance of the patch simulates exactly the acutely macerated and swollen conditions of the lower epithelial layers we so frequently find in eczema. Sir James Paget compares the appearance to that of a balanitis, an apt illustration.

3. The disappearance of the nipple is spoken of by Henry Morris as a "melting away," a very acceptable term.

4. The "malignant papillary" feature, as described by Thin, was a marked element in my first case; much less so in the second. It is a very diagnostic point, and would of itself, I think, instantly resolve any doubts as between it and true eczema.

5. The extreme length of time may be noted in my cases before the appearance of anything like positive evidence of carcinoma. It will be noticed that Sir James Paget gives the limit, as to this, as two years. In my first case twelve years elapsed from attack to death, the latter event not seeming in any way connected with the skin lesion; in the second case considerable over the time mentioned by Paget had already passed.

Second Day.—Morning Session.

The association was called to order at 10 o'clock by Dr. I. E. Atkinson, of Baltimore, Vice-President.

Dr. Wigglesworth, in behalf of Dr. White, presented the statistical report, which was accepted. On motion of Dr. Taylor, a vote of thanks was extended to Dr. Wigglesworth for his most valuable services in performing the work which Dr. White, chairman of the committee, had been prevented from doing by reason of absence in Europe.

The Pathogenesis of Drug Eruptions.—Dr. P. A. Morrow, of New York, then read a paper in which he included this head all symptoms caused by either the internal or the external use of drugs. There was a difference of opinion as to whether they should be classed among the physiological or among the toxicological effects. A large proportion of drug symptoms were the expression of the physiological action of the article used. The term pathogenesis was employed with reference to the close relationship between physiological and pathological effects. Dr. Morrow discussed at considerable length the difficulties of distinguishing between the two effects, especially when influenced by individual susceptibilities and other modifying circumstances. He then reviewed the theories advanced in explanation of the phenomena, such as that of the elimination of the drug through the skin, that of a special affinity for the cutaneous structures, and that of the dynamic action of drugs—all of which had been proved to be fallacious. This was followed by a discussion of the neurotic theory, which he believed best explained the phenomena. The paper closed with a reference to the broad meaning of the term idiosyncrasy, as, after all, anomalous eruptions were determined by the individual rather than by the drug. The nervous element predominated in persons who had an idiosyncrasy.

Polymorphous Changes observed in the Tubercular Syphilide.—The President, Dr. R. W. Taylor, then read a paper based upon a case of syphilis presenting rather early the tubercular eruption described in the books as the non-ulcerative tubercular syphilide. The eruption was general, symmetrical, and copious, had the characteristics of the secondary eruption, and, besides, all the deep-seated peculiarities of the tertiary eruption, so that, in order to place it in its chronological relation, it should be called what the French denominate the intermediate eruption. The patient was a man, forty-seven years of age. Dr. Taylor gave a detailed description of the changes which took place in the eruption, and illustrated them by colored photographs. At one period the eruption appeared strikingly like psoriasis, and subsequently like that illustrated by McCall Anderson, and maintained by Fox to be psoriasis rupioides, a condition which might give rise to the suspicion that what those authors had called psoriasis rupioides was only a late form of a popular or tubercular syphilide. The points of interest in the case were the following:

1. Its resemblance to psoriasis.

2. The colloid degeneration of some of the tubercles coincidentally with the increase of the granulation tissue in others.

3. The degeneration of the colloid tissue into pus, and the formation of bullae.

4. The evidence offered that true bullae might appear in a syphilitic subject, though they resulted from degeneration of tissue rather than from effusion of serum and pus, as occurred, as a rule, in simple pemphigus.

5. The development of tubercles having thick, lubricated, conical, epidermal crusts like those of rupia.

6. The suggestion offered by these lesions that perhaps the psoriasis rupioides of authors was more or less dependent upon syphilis.

7. The formation of true rupia crusts from the bullae above spoken of.

8. The fact that the non-ulcerated tubercular syphilide might be the starting-point of severe and extensive gymnomatic infection.

Dr. Hardaway related the history of a case of psoriasis rupioides, as described by McCall Anderson, occurring in a non-syphilitic patient. The only departure from the appearance of ordinary simple psoriasis was the heaped-up condition of the scales. The mother of the patient had ordinary psoriasis vulgaris.

Dr. Atkinson remarked that Dr. Taylor's paper was also interesting as showing the power of syphilis to assume nearly all phases and simulate almost all diseases.

Psoriasis Affecting the Palms.—Dr. W. T. Alexander, of New York, then read a paper in which he gave the histories of
three cases in non-syphilitic patients. The paper was illustrated by photographs.

The discussion on these two papers was opened by Dr. Graham, who reported two cases of psoriasis of the palms in non-syphilitic patients.

Dr. Morrow stated that while psoriasis was extremely rare upon the palms, and while it probably never occurred independent of its development upon other parts of the body, yet clinical facts proved that it might develop upon the palms. He had seen a number of cases of psoriasis of the palms in non-syphilitic patients.

The President had seen the three cases reported by Dr. Alexander, but had been unable to find any evidence of syphilis. He had not seen psoriasis of the palms, or of the body, that did not exhibit psoriasis of the nails first. That simple psoriasis might affect the palms, he thought there was no doubt. He believed, however, that it had never been seen confined to the palm.

Dr. Morrow had seen a case in which the disease was confined to the palm.

Dr. Alexander said he had been struck with the evanescence of psoriasis of the palm, and perhaps that was the reason why it was seen so rarely. He cited a case in which it appeared and disappeared within a few days without treatment.

Dr. Sherwell said that to prove the absence of syphilis was far more difficult than to prove its presence. Congenital syphilis also formed a part of his theory concerning psoriasis. He had seen simple psoriasis, and then known the patient to contract syphilis, and soon afterward psoriasis of the palms developed, so repeatedly that he must still believe palmar psoriasis had a syphilitic basis. It might be that the psoriasis gave the psoriasis a change, so that it appeared in the palms; that view he was prepared to accept.

A STUDY OF THE COINCIDENCE OF SYPHILITIC AND NON-SYPHILITIC AFFECTIONS OF THE SKIN.—A paper with this title, sent by Dr. J. N. Hyde, of Chicago, was read by Dr. Wigglesworth. The more precise and exact the study of the symptoms in syphilis the more clearly two facts would be recognized, which are strictly related:

1. Syphilis resembled other diseases in its career and its subject to accidental influences much more than had been commonly supposed and taught. 2. When syphilis preceded, co-existed, or followed other pathological conditions, its unity was preserved, and it rarely underwent itself, or induced in other diseases, such a modification as distinctly changed the type of the resulting symptoms. The first statement was supported by the following propositions; the second required clinical demonstration.

a. Allowance being made for a wide field of distribution of its lesions, the study of one hundred consecutive cases of syphilis will convince an unprejudiced observer that such cases resembled each other as closely as a similar number of consecutive cases of pneumonia, typhoid fever, or chronic interstitial nephritis.

b. Syphilis was no exception to the general rule that the patient of greatest vigor best endured its penalties.

c. Syphilis acknowledged subject to the great accidents which commonly and evidently worked changes in all disease processes in man.

d. Syphilis, like other diseases, might lurk obscurely in the system, but, everything said and done, it must be betrayed by syphilitic symptoms, or we could not admit its existence.

e. Vulgar belief to the contrary notwithstanding, cases of syphilis, like those of other diseases, were readily separable into three well-known groups: 1, mild, benignant, or self-limited, requiring no treatment; 2, the grave, malignant, where treatment could have little or no effect; and, 3, those falling between these two extremes, where judicious treatment was capable of turning the scale in one direction and injudicious treatment in the other.

f. There was no specific treatment applicable to every case of syphilis which could safely be employed to the exclusion of all others.

The author proceeded to show how far clinical evidence supported the second of the two general propositions, that which recognized the unity of syphilis displayed, in fairly typical symptoms in subjects affected with other diseases, more particularly those involving the skin. Varieties of seborrhoea and comedo were probably found in more frequent co-existence with syphilis than the other disorders of secretion. Erythema, urticaria, eczema, herpes, the several forms of acne, impetigo, erythema, furunculus, anthrax, and the varieties of dermatitis, frequently occurred in subjects of an active syphilis. Herpes zoster he had not seen in a syphilitic subject. To the subject of the coincidence of psoriasis and syphilis the author directed special attention and gave the histories of two cases with very great detail.

Evening Session.

The association was called to order at 8 o'clock by Dr. Atkinson, Vice-President.

ON THE PECULIAR APPEARANCES OF THE INITIAL LESION OF SYPHILIS AT THE EARLIEST PERIOD OF ITS DEVELOPMENT.—The President read a paper in which he stated that in the "American Journal of Syphilography and Dermatology" for July, 1871, he had published a description of the appearances of an initial lesion of syphilis as observed on the first day of its evolution. These appearances were such that scarcely any one would have suspected the seemingly insignificant spot to be the starting-point of syphilitic infection. A second case of the same kind came under his observation in May, 1883. The details of both cases were given. The first was seen by Professor Boeck, of Christiania, who stated orally to Dr. Taylor that he had observed the same appearance, but Dr. Taylor believed that he was the first to give it a published description. The point of interest in the cases consisted in the peculiar localized silvery appearance of the mucous membrane of the glans penis which was soon to be the site of the true Hunterian chancre. The importance of the early recognition of the nature of this lesion was evident. The practical conclusion was, that at its evolution the initial lesion of syphilis might appear simply as a small non-elevated, silvery spot, seated on the mucous membrane, and without any inflammatory area. This spot might thus remain superficial and free from ulceration for nearly two weeks, after which time, and even before, it might increase in development and assume the appearances of a typical indurated chancre. Dr. Taylor also described two other appearances presented by the initial lesion of syphilis at its earliest period. (1) A minute, slightly rounded, and excoriated spot, the surface of which was neither ulcerated nor depressed, appearing like a most superficial erosion of the epithelial cells of the mucous membrane. Generally these spots were of a somber red color, which later on might become coppery red, and usually they were not the seat of hyperemia. Their further course was one of extension on the surface and in depth. In somewhat rare instances numbers of these spots might appear and produce the multiple herpetic form of chancre. (2) A small, slightly elevated papule having a dry and unbroken surface. This form was most frequently seen in persons with a short prepuce, and in those who had none or only the rudiment of one. It began in this subacute, indolent, and insidious manner, and might run its whole course without any ulceration or excoriation; or it might follow the course of the indurated nodule, or become transformed into the parchment-like chancre. Dr. Taylor further stated that several times he had confirmed Boeck's observation that in
children the initial lesion often began as a very minute shining and silvery spot, similar to that just described.

The Value of a Lotion of Sulphide of zinc in the Treatment of Lupes Erythematosis.—A paper by Dr. Dubring, of Philadelphia, was read by Dr. Stelwagon. Dr. Dubring had used this lotion with marked benefit in the inflammatory superficial forms of the disease, with either discrete or confluent patches, whether recent or of longer duration. He did not put forward for the remedy any specific power over the disease, but in several cases it had been the only remedy tolerated by the skin. The following formula for the lotion was given:

B Sulphate of zinc, Sulphide of potassium, åå, gr. XXX.
Rose water, ½ iij.
Alcohol, 3 iij.

If this strength agreed with the skin, the quantity of the two active ingredients might be increased. The application might be repeated twice or three times in twenty-four hours, the skin being cleansed each time with soap.

Dr. Peiffard was astonished to hear that so many remedies had been employed in the treatment of a case of lupus, because it seemed so well settled that, in order to get rid of lupus, it must be destroyed. The methods of destroying it which, in the majority of cases, acted best were: First, the use of the curette followed by the cautery, frequently the actual cautery; and, second, scarring. Doubtless the lotion would benefit certain cases, but he was unable to understand how it could affect a cure.

Dr. Alexander had at present a case under treatment in which he had practiced scarring three or four times, and the first operation was followed by the disappearance of one patch of the disease. But since then the only effect produced was to make the patch worse.

Dr. Van Harlingen said that he had seen one of Dr. Dubring's cases, and certainly very marked improvement had followed the use of the lotion.

Several of the members failed to see how the lotion could produce much effect on such a disease as lupus.

Dr. Fox had secured his best results in the treatment of this disease by the local application of pure carbolic acid. He painted it over the part at intervals of a week or ten days, perhaps more frequently. In three cases he had succeeded in effecting a complete cure of the disease. The frequency of the application should depend on the rapidity with which the skin peeled off and left a smooth surface ready for another application. He had not found that it aggravated the disease at all. He had also seen good results from the internal use of phosphorus, and thought that perhaps a judicious use of both remedies might secure still better results than had yet been obtained by either alone.

Dr. Stelwagon said that scarring had aggravated the disease in Dr. Dubring's cases; that pure carbolic acid was applied without effect; and that they were benefited by this lotion only, which was applicable chiefly to the superficial variety of the disease.

Dr. Peiffard said that the dermatitis referred to by Dr. Stelwagon and Dr. Alexander occurred as a matter of necessity after scarring, but it did no harm. Scarring should be performed with great thoroughness, and the dermatitis which followed was of advantage. It was substantially the treatment recommended by Hardy, namely, to excite a sufficient amount of new inflammation to strangulate the new lupus cells.

Dr. Hardaway believed firmly in scarring and multiple puncture. He had treated one case successfully, however, by electrolysis.

Report of a Case of Ather with Microscopic Examination.—A paper by Dr. Dubring was read by Dr. Stelwagon. The case was one which came under the observation of Dr. George B. Weston, of West Virginia, and to him Dr. Dubring was indebted for the specimen with the notes. Only a few cases of this disease had been reported in this country, and with reference to them the conclusion had been reached that it was caused by the application of a ligature. The patient was a negro, and the specimen consisted of one of the toes. The microscopic examination was made by Dr. Henry Wilu, of Philadelphia, who made it with great care, and came to the conclusion that the principal changes indicated a general inflammatory condition.

Dr. Sherwell had treated many patients from Jamaica and San Domingo, but especially from Turk's Island, had made inquiry concerning this affection, and had been led to the conclusion that it was due to traumatism from the application of a ligature around the toe; lazy negroes applied a ligature, and became subject to what was known as "ring-toe."

A Peculiar Papillary Eruption.—Dr. Hardaway read a paper in which he described a case that had occurred in an otherwise healthy brunette, the eruption affecting the left cheek and both hands, and having existed at least a year, but without any special inconvenience. The size of the papules varied from that of a grain of wheat to that of a split pin, and they were non-pedunculated. The eruption was discrete, of a dull lemon color, and of pellucid appearance. The papules were solid to the touch, and gave the appearance of having liquid contents, but nothing could be obtained by puncture except blood, and nothing could be squeezed from the papules. The eruption disappeared under treatment without leaving any trace whatever. He had had five cases. The treatment for the most part had consisted in the use of a tar-and-mercury ointment. All the cases were chronic. There was no evidence whatever that it was contagious.

Such an eruption as described by Dr. Hardaway had not been seen by any of the members of the association.

Lymphangioma Cutis with Dermatolysis.—Dr. J. E. Graham, of Toronto, reported a case, illustrated with photographs. The patient was a woman twenty-one years of age. When five years old a tumor appeared in front of the elbow which gradually extended upward and downward. The history from that time had been one of constant increase, and the growth had increased very rapidly during the last year. Its presence had not produced inconvenience. On the anterior surface of the arm the integument hung down in bag-like pouches which changed in color as the arm was raised or hung down. The papillary layer of the corium was hypertrophied, and the skin presented deep furrows. There was brown pigmentation near the elbow, and a few black hairs existed on the surface. The entire growth had a peculiar velvety feel. There was thickening of the skin, but no induration whatever. At the middle of the forearm there was a small tumor which felt like a mass of blood-vessels beneath the skin. The arm could be made smaller by pressure, and especially the small tumors, of which there were two or three. The tumors were not painful. The affected arm was almost as strong as the other. It was possible that the small tumor seen existed at birth, but had been unrecognized. Dilatation of the lymph channels was the probable pathological lesion.

Dr. Fox had seen one case which would bear comparison with Dr. Graham's.

Dr. Atkinson had seen one case which was almost identical with that reported by Dr. Graham, except that the growth was situated higher up upon the arm. He thought that there was dilatation with new growth of the channels, and regarded such
a case as affording striking proof of the inaccuracy of the view put forward by Dr. Formal concerning the nature of tubercle, as we did not observe tubercular inflammation in these cases, where it was well known that the lymph channels were obstructed.

Dr. Puffard thought it practicable to remove the growth in sections by the use of the galvano-caustic ligature.

Dr. Atkinson thought the probable cause of the disease would remain, and that removal of the growth would be followed by a return of the affection.

Dr. Shewell referred to a case of general lymphangioma.

Friday.—Third Day.

The President called the association to order at 9.30 a.m. The first order of business being the induction of newly elected officers, Dr. R. W. Taylor, of New York, re-elected President, congratulated the association on its prosperity and the steady increase of the good work performed, and thanked the members for the confidence expressed by again electing him as their presiding officer.

The Vice-Presidents for the ensuing year are Dr. Arthur Van Harlingen, of Philadelphia, and Dr. J. E. Graham, of Toronto; Secretary, Dr. W. T. Alexander, of New York; Treasurer (re-elected), Dr. George H. Rome, of Baltimore.

The members then examined microscopic sections which had been prepared by Dr. Henry Wile, of Philadelphia, illustrating Akinhna and Malignant Papillary Dermatitis (Paget's disease).

The association then adjourned, to meet, on the last Wednesday in August, 1884, at West Point.

NEW YORK SOCIETY OF GERMAN PHYSICIANS.

A stated meeting was held November 24, 1882, Dr. B. Schraut in the chair.

Anesthesia of both Corneas.—Dr. A. Seissel presented a patient with this affection which had lasted for several months. No ulceration had taken place. He discussed the theory of trophic nerves, and the experiments made upon rabbits, with a view of disproving that theory. In these experiments the ears of the animals were made to protect the cornea by being stitched to the skin in such a way as to cover the eyes. The cornea remained intact after division of the frontal nerve, while they speedily exacerberated if no such precaution was taken.

Dr. E. Greising said that patients suffering from anesthesia of the cornea should be told to close their lids often and to use disinfecting washes frequently. If this advice was carried out faithfully from the beginning, destructive ulceration of the eye would always be avoided.

Dr. A. Schafinger mentioned a case of anesthesia of both corneas in a patient who had been under his charge at the Mount Sinai Hospital. There was also ptosis in one eye. When first seen, an ulcer had already formed in the eye in which there was no ptosis, while the other, which was protected by the paralyzed upper lid, remained intact. Under anti-inflammatory treatment the cornea recovered sensibility, the lid became movable, and the corneal ulcer was healed.

An Exorously Thickened Peritoneum.—Dr. A. Jacobi showed the specimen, the nodular masses having given rise during life to a mistaken diagnosis. The patient was forty-nine years old when she died. Twelve years before her death ascites made its appearance, with loss of flesh. The veins over the abdomen were considerably distended, and the spleen was enlarged. There were neither hemorrhages nor diarrhea. The diagnosis of cirrhosis of the liver was made, and subsequently confirmed by Professor Friedreich, of Heidelberg, who was consulted by the patient during a visit to Europe. Two years later two gallons of fluid were removed by tapping. After the lapse of twelve months the operation had to be repeated. There was no ileus at any time. Palpation of the liver revealed increased size and toughness. The condition of the patient improved, the spleen became smaller, but slight ascites always remained. Some hard nodules could be felt which appeared to be tumors located within the abdominal cavity. She died from hemorrhage of the stomach. At the autopsy, cirrhosis of the liver was found. The parietal peritoneum was thickened to the extent of an inch by chronic inflammation, and contained calcareous masses. The nodules formed by the inflammatory deposits had been mistaken for intra-abdominal growths.

A Collapsed and Lepartized Lung.—Dr. Jacobi also presented this specimen, which had been removed from the body of a child. The little patient died from empyema, which had been neglected. A fistula had formed, and this, in connection with the secondary curvature of the spine, led to the diagnosis of Poti's disease, for which the child was put into a plaster-of Paris jacket in one of the city hospitals. This was so much soiled by the secretions that it had to be removed. Albumin appeared in the urine, profuse diarrhea and anasarca set in, the patient became extremely anaemic, and finally succumbed. At the autopsy, amyloid degeneration of the liver, spleen, and kidneys was found. The pleura on the diseased side was somewhat thickened. The bronchial glands were considerably enlarged, and showed caseous degeneration.

Melano Sarcoma of the Orbit.—Dr. Greising presented a phtisical globe which he had enucleated from a man fifty-five years of age. The globe was the seat of melano-sarcoma. The sight of the eye had been destroyed by panophthalmitis eight years ago. The shrunken globe remained quiescent for five years. For the last three years it had been red and painful, and the patient also complained of headache. For the last three weeks he vomited, and the sight of the other eye began to fail. On examination with the opthalmoscope, the optic nerve of this eye was found to be atrophic. The shrunken globe, which was very hard and perforated by large veins, was now enucleated. After division of the conjunctiva and the muscles, the globe did not protrude as usual, and, by introducing a finger, a tumor could be felt at the junction of the globe and the optic nerve. After exision, the eyeball was found to be filled with masses of melanomasarcoma which had invaded the optic nerve and the chiasma, and thus caused atrophy of the other optic nerve, and finally death by implication of the brain. Sarcoma of the eyeball usually extended by way of the orbital fissures, and rarely by way of the nerve, as in this case. Each had collected 250 cases of this growth, among which only ten proved fatal by direct extension to the brain, the remainder causing death by metastasis. One case similar to the one described by Dr. Greising had been published by Dr. H. Knapp.

Perforation of the Intestines in Typhoid Fever.—Dr. H. J. Boldt presented the intestines of a patient who had died from perforation in the course of typhoid fever. There had been no diarrhea in the course of the disease.

Dr. A. Jacobi remarked that specimens of intestines from patients who had died of typhoid fever which had run its course without giving rise to diarrhea had already been presented to the society on two previous occasions. Such cases could be frequently observed in this country.

Dr. G. Langmann said that they were not rare in Germany either, where they went by the designation typhus ambulatorius. Constipation could occur in typhoid fever in spite of the presence of ulcers in the intestinal tract.

Congenital Cyst of the Neck.—Dr. A. G. Gerster presented a specimen of congenital cyst of the neck which had ad-
bled to the transverse process of the sixth cervical vertebra. Its removal was accomplished with some difficulty, as the large vessels of the neck had to be exposed and one branch of the internal jugular vein had to be ligated. The posterior wall of the cyst was found to be attached to the sternocleidomastoïd muscle by inflammatory adhesions, and therefore a portion of this muscle had to be removed, together with the tumor. An antiseptic dressing was applied. The patient had a fit of coughing, in consequence of which a copious haemorrhage took place into the cavity of the wound. This was probably caused by the slipping of the cautery off the branch of the internal jugular vein which had been ligated. The coagulated mass did not decompose, but gradually shrank and disappeared at the end of two weeks. The wound healed by first intention. If it had not been for the Lister dressing, the haemorrhage would have given rise to disagreeable complications.

Dr. H. Knapp remarked that after certain operations upon the eye very extensive haemorrhage into the surrounding cellular tissue was apt to take place. Absorption always took place without any difficulty, though no antiseptic precautions were employed.

Dr. Gerster replied that in the cases mentioned by Dr. Knapp the haemorrhage was subcutaneous, and the blood did not come in contact with the air. It was different in cases like the one reported by him.

Cæsarean Section.—Dr. H. J. Geygere presented the uterus and the kypheotic pelvis of a woman on whom he had performed the Cæsarean section, for an account of which see the "New York Medical Journal" for January 22, 1888, p. 103.

A stated meeting was held December 22, 1882, Dr. A. G. Caillé, in the chair.

Blepharo-plasty according to the "English Method."—Dr. E. Grexinger presented a patient upon whom he had performed blepharo-plasty according to the "English method" two months ago with perfect success. The case will be found in the "New York Medical Journal" for July 28, 1883, p. 106.

Injury of the Brain without Impairment of its Function.—Dr. H. Knapp presented a young man who, two years ago, had met with an accident caused by the premature explosion of a quantity of gunpowder. There was an enormous defect in the left side of the frontal bone, covered by cutaneous tissue. There were distinct cardiac and respiratory pulsations of the brain. There had been also loss of substance of the brain itself without impairment of its function.

Dr. A. Jacobi mentioned the case of a boy who had met with an accident ten years ago, which resulted in the loss of a considerable part of his skull. No brain substance was lost. The boy recovered.

Dr. J. Redlich stated that the patient presented by Dr. Knapp, upon being questioned, admitted that he had been very irritable since the accident happened to him. In the celebrated "American Crowbar Case" the loss of substance had also involved the frontal lobes, as in the present case, and no disturbance of either motility or sensibility ensued. The patient resumed work, but had to be discharged by his employers on account of an unoverbearable temper which had developed after the accident. In experiments performed upon monkeys, no disturbances of either sensation or motility were produced by electric excitation or mechanical lesions of the frontal lobes.

Stenosis of the Auriculo-ventricular Opening.—Dr. J. Kéchén presented a specimen of congenital stenosis of the right auriculo-ventricular opening, and of a chorda tendinea stretched horizontally between the flaps of the mitral valve. The description of the specimen has been published elsewhere.

Dr. A. Jacobi held that the changes in the specimen presented were due to endocarditis, which had developed during the last months of pregnancy. This view he based upon the size of the heart, which was normal.

Acute Nephritis in an Infant.—Dr. Caillé reported a case of acute nephritis in an infant only a few days old, and presented its urinary apparatus. The child was in a healthy condition when born, and had not been exposed to any injurious influences. For six days it progressed satisfactorily. On the seventh and eighth days it did not urinate, and refused the breast. Dr. Caillé first saw the infant on the tenth day. It was very weak. There was increased frequency of respiration, without any rales. The pulse was accelerated. The heart-sounds were normal. Pressure upon the region of the kidneys caused the child to moan. The bowels had been moved freely, but the bladder had been emptied only once in thirty-six hours. The color of the urine was greenish-brown. Dr. Caillé diagnosed renal colic caused probably by concretions. He ordered the child to be packed in warm flannel, and prescribed small doses of opium. On the eleventh day the child was much better, but on the twelfth a relapse took place and the little one succumbed. At the autopsy the renal portion of the peritoneum appeared dark red. There were numerous extravasations of blood in the areolar tissue surrounding both kidneys. The kidneys themselves were dark red and enlarged. Both ureters and the bladder were normal. The renal epithelia were enlarged and opaque. The other viscera were in a state of venous congestion. Dr. Caillé thought that acute nephritics occurred rarely in early infancy.

Dr. A. Jacobi supposed that the cause of the inflammation of the kidneys in this case had been concretions of uric acid.

Dr. Boldt said that he had met with a similar case in a baby three months old, with this difference, however, that this baby recovered.

Dr. A. Seibert, who had assisted at the autopsy, said that there were numerous hemorrhages in the liver as well as in its capsule. This circumstance had inadvertently been omitted by Dr. Caillé.

Dr. A. Jacobi said that such hemorrhages were frequently met with in cases of fatty degeneration. He inquired whether there was any suspicion of hereditary syphilis.

Dr. Caillé said that there was not.

An Improved Microscope Slide.—Dr. Caillé also showed an improved slide for microscopical objects. It was well adapted for the prolonged observation of living animalia. Such slides were made by the inventor, Gustav Weber, 265 Broome Street.

A New Current Selector.—Dr. George W. Jacoby showed a new current selector which had been devised by him in conjunction with Dr. Rudisch, and for which he claimed the following advantages:

1. It enabled the operator not only to increase or diminish the number of cells he wished to include in the circuit, but also to select the cells from any part of the battery he pleased. With the ordinary current selectors this was not possible. If one wished to use less than the entire number of cells, the same cells were made to work every time, and in this way one part of the battery was soon exhausted.

2. Good contact was secured by springs concealed in the riders.

3. Its construction was very simple, and it was therefore easily kept in good order.

Tracheotomy in Diphtheria.—Dr. A. Jacobi related a case of diphtheria, occurring in a strong child seven years old, in which he had performed tracheotomy two weeks ago. The operation was followed by marked relief, but the diphtheritic process continued to progress. The wound was soon found covered with a diphtheritic membrane, and the tissues were destroyed so rapidly.
that soon the end of the thumb could be introduced into the aperture made in the trachea. The tube was nevertheless left in. The child was doing fairly well for two weeks; at the end of this time paralysis of the velum palati supervened, in consequence of which pneumonia developed, and the child died on the nineteenth day. This case shows that recovery should never be assumed to be established before the removal of the tube, since fatal complications might arise at any time.

Dr. Boldt mentioned a case of diphtheria in which he had performed tracheotomy two years ago. In this case the tube had to be left in for about eighteen days. Paralysis of the vocal cords supervened in the course of the disease, but the child nevertheless recovered.

A discussion of the different methods of tracheotomy followed, in the course of which Dr. A. Jacobi stated that he preferred the infra-thyroid method, and that for many years he had used exclusively tubes made of hard rubber.

A. G. Geister, M. D., Secretary.

Miscellany.

Therapeutical Notes.—Extract of Dounjaké Bark and its Alkaloid, Dounakine. —M. Vulpius ("Union médicale," August 4, 1888) has reported to the French Academy of Sciences some interesting particulars concerning the bark of the dounjaké and its alkaloid, dounakine. The dounjaké is a shrub found on the west coast of Africa. Its bark, used empirically as a febrifuge by the natives about the Rio Niteri, is of an orange-red color, and has a very bitter taste. It consists of superimposed layers that are easily separated from one another. An organic base may be isolated by the following process: The pulverized bark is boiled in water acidulated with sulphuric acid. The filtered liquid is treated with lime. The precipitate is placed upon a cloth, drained, and compressed. The dried mass is worked up in a wet bath with alcohol. The alcoholic solution, concentrated by distillation and afterward evaporated in vacuo, yields a substance which is to be purified by several successive evaporations. The product thus obtained is a yellow powder formed of rhombohedral crystals, visible by means of the microscope. It is bitter in taste, soluble in water and in alcohol, and alkaline in reaction. Winkler's liquid precipitates from it phospho-tungstic and phospho-molybdic acids, but it does not become turbid on the addition of Boucharad's reagent. It may be chased among the alkaloids under the name of dounakine. The bark of the dounjaké does not yield sialin, as was supposed by Venturi. Experiments performed for the purpose of determining the physiologic action of the alcoholic extract of dounjaké bark and of dounakine gave the following results: In the case of a frog, the hypodermic injection of a quantity of the extract representing two grammes of the bark caused death at the end of thirty-six hours. In the case of a young cobaye weighing 100 grammes (about a fifth of a pound), the extract from 1 gramme of the bark induced death in fifteen minutes. Eight milligrammes (gr. ¼) of dounakine, equivalent to about two grammes of the bark, killed a frog in twenty-six hours. Thirty-four milligrammes of the alkaloid, given hypodermically, killed a cobaye weighing 700 grammes (about 1 pound) in twenty-four hours.

The physiologic action of the extract of the bark and that of the alkaloid are identical, and may be given in brief thus: In the case of the frog, some general weakness, accompanied with a diminution of spontaneous and reflex movements, was noticeable in from two to five minutes. Soon the animal was unable to maintain its normal attitude. It would keep indefinitely any position given it by the experimenter, no matter how unusual or odd. However, the muscular contractility and nervous excitability were preserved, and the pulsations of the heart were not sensibly affected. The foregoing phenomena, which take place in what the experimenter calls the "first period," were followed by the complete resolution of the "second period." The respiratory movements became lessened in frequency, irregular, then intermittent, and then ceased altogether. The pulsations of the heart were retarded and afterward irregular. Reflex movements were abolished progressively. Finally the heart ceased to beat.

Special Surgical Appliances for Disabled Soldiers and Sailors.—We have received the following communication, dated August 28, 1883, from the Surgeon-General of the army:

"Congress having appropriated a small sum for furnishing special surgical appliances to those disabled in the military or naval service, your co-operation is respectfully invited in order that this relief may reach the class of persons intended to be benefited.

"This office is desirous of obtaining authentic information regarding all existing cases of severe and unusual injuries. Should you have occasion to report such, it will be found useful to bear in mind the following points:

"1. As no money commutation is authorized, only such cases need be presented as offer a fair prospect of being relieved by surgical or mechanical appliances.

"2. Artificial limbs and apparatus for disabled limbs being otherwise provided for by law, the injuries here in view are almost exclusively those affecting the head, face, or trunk.

"3. As trusses are furnished under special legislation, heretofore, when not complicated with other injuries, is not to be understood as covered by this appropriation for special appliances.

"4. As the appropriation is small, it is proper that it be expended only on the most meritorious cases. It is therefore not intended to furnish appliances which are ordinarily within the means of the individual, nor those that are of a character so perishable that it would be difficult to keep up the supply. Regard is to be had chiefly to the severity of the injury, and the ability of the sufferer, unassisted, to procure relief."
The Breeding of Cholera Germs.—Professor William B. Carpenter has written the following letter to the London “Daily News”:

“Entirely agreeing with my friend Professor Tyndall in the doctrine that the human intestine is a breeding-ground for the germs of cholera, and that the conveyance of these germs by infected waters is a potent factor in the spread of that disease, I think it most dangerous to assume—what his language seems to me to imply—that the human intestine is the only breeding-ground for cholera germs, and the transmission of them by tainted water the chief (if not the only) factor. Having been throughout my professional life, from the first invasion of Asiatic cholera in 1831, a careful student of the conditions of its propagation (which I often discussed with my late friend, Dr. E. A. Parkes), I am perfectly satisfied that there are many cases which clearly indicate that cholera germs can also breed outside the living body in collections of decomposing organic matter, and can be thence diffused by the atmosphere—a doctrine which every one who is acquainted with the propagation and diffusion of putrefactive bacteria must regard as involving no inherent improbability. The epidemic of 1848-'49 supplied three very marked examples of this kind, which I was accustomed to bring before my class year after year. Professor of forensic medicine and public hygiene in University College.

“One of these occurred in a suburb of Albury, in Northumberland, where almost every inhabitant of a certain row of cottages was smitten in one night with either cholera or cholera diarrhoea. These cottages had gardens behind them, at the far end of which was a row of very filthy piggeries. This almost universal outbreak followed immediately upon a change in the direction of the wind, which came to blow directly over the piggeries to the cottages. The second case was essentially similar, but on a much larger scale. It occurred in the city of Baltimore, which was situated out of the town, in what was believed to be a peculiarly salubrious locality. The municipal authorities of that city had taken very active and (as the event proved) very efficient measures for warding off the disease from its inhabitants. Though cholera was very severe in New York, Philadelphia, and Washington, only a few imported cases occurred in Baltimore itself. But in the poorhouse, containing about eight hundred persons, a most fearful outbreak suddenly occurred, the deaths being as many as thirty a day. The place had been carefully cleansed, there was no overcrowding, and the drainage was believed to be sufficient. But a more careful examination disclosed the fact that the drains, instead of being constructed into a neighboring ravine down which a stream ran, ended in a piece of marshy ground, covered with rank grass, that ran between this ravine and the back of the poorhouse inclosure. And it was then noticed that the outbreak had immediately followed a change of wind which caused it to set over this marsh toward the back of the poorhouse. With this clue, the singular phenomena of the outbreak were at once found explicable. All the first cases occurred in the back rooms of the building, and the number and severity of them bore a most remarkable relation to the local conditions which made one part of it rather than another the recipient of the fatal germ-bearing air currents. The cause being thus detected, efficient measures were immediately taken to antagonize its action, and the plague was at once stayed.

“Professor Tyndall may recollect being present, some years ago, at Slon College, when I brought this case before an assembly of clergy¬men in an address on the ‘Regain of Law,’ and asked whether any of my hearers believed that, if all Baltimore had gone down on its knees for a week in penitence and prayer, without taking the human means dictated by the study of the ‘laws’ of their divine government, and of the consequences of the infraction of them, this favorable result would have been brought about. My third case, which was in some respects even more striking, was related to me by an old fellow-student, who had been in Mexico at the time when the cholera epidemic reached that country, and was residing in a town (whose name I forget) of about twenty thousand inhabitants, situated on a level plateau on a mountain side at a considerable elevation. He noticed that a large proportion of the earlier cases occurred along a particular line, and that the subsidence of the disease along this line was followed by a sudden outbreak of the like kind along another line at an angle with the first; and he further noticed that this second outbreak had been immediately preceded by a change of wind. Strongly suspecting, therefore, that the choleric miasmata must have been wafted along each line from a common focus, he ran the two lines together as a bee¬hunter does, and found at their point of convergence an inclosed yard containing an enormous heap of filth. What doubt can be reasonably entertained that this heap had served as the nidus in which the cholera germs had propagated, and from which they had been atmospherically conveyed?

“In one important respect, however, the Baltimore case is yet more instructive, since all the evidence there pointed to an original atmospheric implantation of the disease germs in the nasmastic marsh in which they bred, and from which their multiplied progeny were wafted to the unfortunate inmates of the poorhouse; for there had not been, as in all the known instances of poisoning by water supply, any previous case within the building from which the primal germs could have been furnished, while the local conditions precluded the idea that the marsh could have been contaminated by any other direct human communication. In the light of these cases, to which many more might be added, I hold it to be at the same time unscientific and unsafe to limit the breeding-ground of cholera germs to the human intestines, and to affirm that they can neither propagate themselves in fecal or other decomposing organic matter outside the living body, nor be introduced into it otherwise than through the mouth. Professor Tyndall lays great stress on the analogy of typhoid, but he must be aware that some of our best authorities do not admit his exclusive doctrine, even in regard to that disease. And, even if that doctrine be conclusively established, it could not invalidate the evidence I have now adduced in proof of the atmospheric diffusion of cholera germs bred outside the human body; since, if I am not mistaken, there are no cases on record of sudden and simultaneous outbreaks of typhoid under conditions at all parallel.”

The Courteous, or Mechanical Nurse.—After two years’ trial, says the “Lancet,” the “courteuse has proved so decided a success that a brief description of this ingenuous contrivance may be desirable. It was in 1878 that Dr. Tarnier, when visiting the apparatus devised by M. Odile Martin for artificially hatching and rearing chickens at the Jardin d’Acclimatation, suggested that a similar method might be applied with advantage to infants, especially in cases of premature birth. Two years elapsed, however, before any attempt was made to carry out this project; but in the course of the year 1880 a couruse was made, and brought to the hospital of the Maternité. This is a plain wooden case or box, measuring about 2 ft. 6 in. by 2 ft. 4 in., and 2 ft. 4 in. in height. The box has a double covering, the space between being filled with sawdust to retain the heat, and is divided into two parts. The lower half contains a reservoir, which holds about sixty litres of water, and is fed by a patent boiler that stands outside the box, and is warmed by an oil lamp; or hot water may be used without recourse to the lamp. The upper portion of the box forms a warm chamber, where a little basket or cradle is placed, large enough to hold two infants. From an opening at the side, this cradle may be withdrawn, while the top of the box has a double glass covering, so that the children and the thermometer lying by their side can be constantly watched. If the water used in the first instance is cold, it takes a long time to attain the required temperature; but once this is done the lamp need only be relit three or four times during the course of the day. It is best to warm the apparatus while the infants are being fed or washed. The temperature within the couruse is generally maintained at 86° F., and, though the contrast in withdrawing the child to be fed or washed is very great, amounting often to 30° F., colds are not so frequent as among the infants nursed in the ordinary manner. Altogether the experiment is considered so successful that it is proposed to supply all the hospitals of France with a couruse, and there is every reason to anticipate good results from this measure. Nor is this all. A small portable couruse is now about to be tried which could be carried by hand from house to house. After this we shall probably have par¬ulators constructed on the same model. In conclusion, we should remark that, though no very careful experiments have been made with respect to the ventilation within the couruse, yet this is evidently sufficient. Apertures are made in the lower portion of the box, the
MISCELLANY.

[NEW YORK MEDICAL JOURNAL]

These new frequently norrhagic tritis linitis exulcerated subsidence Bartholinitis within primarily, or when the inflammatory process has somewhat diminished.

1. Blemorrhagia in the female has a marked tendency to localization in certain well-determined points of the vulva or the vagina, either primarily, or when the inflammatory process has somewhat diminished.

2. Generally, blemorrhagia localizes itself in the glands of the genital apparatus.

3. Blemorrhagia may localize itself exclusively in the vulva. This constitutes blemorrhagia vulvitis.

4. But it may offer more intimate localizations and secrete itself within the glands of Bartholin, in the peri-urethral follicles, or in the disseminate glands, at the level of the labia minora or the fourchette.

5. Blemorrhagie Bartholinitis is quite frequent. It may present the following forms:

   The acute form, terminating by resolution or induration, rarely by suppuration.

   The subacute form, suppurring invariably, the blemorrhagic Bartholinitis then becoming complicated with a phlegmonous peri- Bartholinitis. The peri-glandular pus is not blemorrhagic, while the intra-glandular pus presents all the characters of blemorrhagic pus.

   The chronic form, if the inflammation becomes complicated with peri-tonitic accidents by the intermediary of a lymphangitis or of a juxta-uretericadenitis (adeno-lymphitis), which especially leads to adenopelvi-peritonitis.

6. The peri-urethral folliculitis may be simple. It then presents well-defined clinical symptoms.

   Hypertrophic. It then becomes the point of departure of urethral polypi.

   Suppurative. In this last condition the disease is contagious. The contagion is effected by the introduction of a drop of blemorrhagic pus into the canal of the urethra, one of these follicular abscesses being broken during the act of coition.

7. Blemorrhagia rarely localizes itself in the glands of the labia minora or in the form of a patch in one or several vulvar glands situated at the level of the fourchette.

8. All the points of the localization of blemorrhagia may become exuberated under the influence of inflammation, and thus become a point of entry for the phlegmonous or suppurative virus.

9. Blemorrhagia may localize itself, when it occupies the vagina, in the cul-de-sac, in the folds which are observed on the mucous surface, in the urethral neck, or even in the cavity of the uterus itself.

   In the latter case it is frequently complicated with peri-urethral accidents by the intermediary of a lymphangitis or of a juxta-ureteric adenitis (adeno-lymphitis), which especially lead to adenopelvi-peritonitis.

10. It is rare that blemorrhagia localizes itself in the rectum; nevertheless, this fact has been observed, especially in the female.

   11. It is important to recognize localized blemorrhagia in the female, and not to confound it with dermatoses, such as herpes or zona. Blemorrhagie Bartholinitis should be differentiated from traumatic Bartholinitis and cysts of the vulvo-vaginal glands.

   Likewise it is important to distinguish peri-urethral folliculitis from inflammatory vegetations, and blemorrhagie vulvitis from simple vulvitis. Physicians ought also to be able to refer a blemorrhagie me-tritis to its true cause.

12. The prognosis should embrace two factors:

   a. The patient is, by the fact of her localized blemorrhagia, subject to acute recurrences of a severe character.

   b. She may become contagious, if in any circumstance whatever should reactivate the chronic inflammation and induce the least possible puriform or purulent condition.

13. In order to radically cure the disease, it is necessary, after the subsidence of the acute symptoms, to modify the inflamed points by energetic cauterizations, to even incise the gland of Bartholin and induce suppuration, if it should be the seat of localization of the blemorrhagia.—Jour. of Cutan. and Venerel. Dis.

Bathing Infants in the Sea.—At the present season a mistaken and mischievous practice is much in vogue. Daily contact is inflicted on thousands of tender and helpless infants by forcibly plunging their bodies, in spite of shrieks and struggles, into the open sea. This cruel and time-honored process may now be seen in full operation at any sea-side resort. Affectionate mothers hand over their infants to stalwart and impassive bathing-women, to be plunged head foremost into the sea, under the absurd notion that the procedure vastly benefits the little ones. Day after day, with relentless regularity, very young children and babies are borne out amid the waves and subjected to their dreadded dunking, in the firm belief that their trembling bodies, often writhing to the verge of convulsions, are thus made healthy and hardy. All experience on the subject, and the teachings of all medical authorities on sea-bathing, agree in support of the two following rules—namely, that a child under two years of age ought never, under any circumstances, to be bathed in the open sea, and that no one child or adult, can enter the sea without danger while under the influence of emotional excitement. Under two years of age, a child's body is too weak to gain any benefit from the shock of immersion in the open sea. Its nervous and circulating forces are too feeble for the development of that vigorous reaction without which sea-bathing is either useless or hurtful. In the absence of strength for such reaction, a sea-bath tends to enfeeble the child's body, and predisposes to internal congestions. At any age, the shock of immersion in the sea brings risk of danger and even of death, when the emotions are powerfully excited, and especially when the mind and body are dominated by that most depressing of human emotions—fear. Infants are not always bathed in the sea merely with the intention of making them strong. There is an old sea-side tradition that babies diligently bathed become fearless in the water when they grow up. This notion is also false. Than that infants gain courage by being plunged in the sea, it is more probable that many a nervous child has acquired a dread of bathing which no after-experience could remove, because it was compelled in fear and trembling to plunge under water. If a child be sufficiently robust to develop a good reaction, it is to be over two years of age, and, above all, if it be not afraid, it may be bathed in the sea with advantage. If any of these conditions be wanting, sea-bathing for children is likely to be positively injurious.—British Med. Jour.

Pyrethrum Powder.—At a recent meeting of the Horticultural Society of Montgomery County, Ohio, it was stated that pyrethrum powder was so much adulterated by dealers that it was advisable for persons wishing to employ this insecticide to raise the herb for themselves, and that the Agricultural Bureau at Washington would furnish the seeds on application.

NAVAL INTELLIGENCE.—Official List of Changes in the Medical Corps of the Navy during the week ending September 1, 1883.—Surgeon T. C. Walton, detached from the Hospital at Washington, and ordered to the Naval Academy. —Surgeon W. J. Simon, detached from the United States steamer Constellation, and, after completing temporary duty as member of a board at Annapolis, Md., to be placed on waiting orders. —Passed Assistant Surgeon W. A. McClurg, detached from the United States steamer Dale, and ordered to the Naval Academy. —Assistant Surgeon Oliver Diehl, detached from the United States steamer Constellation and ordered to the Naval Academy. —Passed Assistant Surgeon M. D. Jones, ordered to temporary duty at the Naval Hospital, Washington, D. C.

THE NEW YORK MEDICAL JOURNAL, September 15, 1883.

STUDENTS' NUMBER.

THE MEDICAL COLLEGES OF THE UNITED STATES AND CANADA.

Hereunto we give as much information as our space will allow concerning sixty-seven medical colleges of the United States and Canada. The list includes all the non-sectarian colleges recognized by the Illinois State Board of Health that we have been able to obtain trustworthy data from. The arrangement is by States, in alphabetical order, and the different colleges in individual States are mentioned in the order of their age. In many instances more particulars might have been given with advantage, but, as lack of space has precluded our following this course, we have been careful to give the names and addresses of the deans or other officers to whom application for further information may be made.

It will be seen that we have made no reference to courses of instruction for graduates, or to institutions wholly devoted to graduate courses. Those matters will receive full consideration in our College Commencement Number, to be issued in February. To that end, we now take the liberty of asking the proper officers of such schools to send us two copies of their announcements, together with such further information as may seem likely to be of interest to the profession. It affords us pleasure to acknowledge the kindness of college officials in providing us with data for this issue.

Alabama.

MEDICAL COLLEGE OF ALABAMA, MOBILE, ALA.

Faculty.—F. A. Ross, M. D., Materia Medica and Therapeutics (emeritus); E. P. Gaines, M. D., Physical Diagnosis and Diseases of the Chest; George A. Ketchum, M. D., Theory and Practice of Medicine; E. H. Fournier, M. D., Materia Medica, Therapeutics, and Clinical Medicine; W. H. Anderson, M. D. (Dean), Physiology; J. F. Heustis, M. D., Surgery; Charles Mohr, Jr., Lecturer on Chemistry; Goronwy Owen, M. D., Obstetrics and Diseases of Women and Children; Caleb Toxey, M. D., Anatomy; W. H. Sanders, M. D., Diseases of the Eye and Ear, and Histology; Rhett Goode, M. D., Lecturer on Clinical and Minor Surgery; F. C. Caudill, G. P., Lecturer on Practical Pharmacy; D. E. Smith, M. D. (Adjunct), Surgery; E. W. Ayxal, M. D. (Adjunct), Physiology; W. B. Pape, M. D. (Adjunct), Obstetrics, etc.; Rhett Goode, M. D., Demonstrator of Anatomy; E. Dickson, M. D., Assistant Demonstrator.

The twenty-fourth annual session will begin October 18, 1883, and will continue five months.

Requirements for Graduation.—These embrace nothing peculiar.

Fees.—Matriculation, $5; lectures, both at college and hospital, $75; dissection, $10; graduation, $25. All students are required to take the dissection ticket.

The faculty has established a chair of pharmacy in connection with the college. The fees for the course will be: Matriculation, $5; tickets, $30; graduation, $20. Two courses will be required for graduation. Regular medical students who desire to take the course can do so by paying for the ticket in practical pharmacy ($10) and for the diploma.

For further information address W. H. Anderson, M. D., Dean, No. 70 St. Francis Street, Mobile, Ala.

Arkansas.

MEDICAL DEPARTMENT OF ARKANSAS INDUSTRIAL UNIVERSITY, LITTLE ROCK, ARK.

Faculty.—P. O. Hooper, M. D. (President), Practice of Medicine; Edwin Bentley, M. D., Institutes and Practice of Surgery; A. L. Breysacher, M. D., Obstetrics and Diseases of Women and Children; J. A. Durrell, Jr., M. D., Anatomy; John J. McAlmont, M. D., Materia Medica, Therapeutics, Hygiene, and Botany; James H. Southall, M. D., Institutes of Medicine; Roscoe G. Jennings, M. D., Clinical Surgery and Dermatology; J. M. Buchanan, M. D., Medical Chemistry and Toxicology; L. P. Gibson, M. D., Demonstrator of Anatomy; T. E. Merrell, M. D., Ophthalmology and Otolaryngology; James H. Lenow, M. D., Diseases of the Genito-Urinary Organs; Ciaiborne Watkins, M. D., Physical Diagnosis and Clinical Medicine; Louis R. Stark, M. D., Gynecology; John Waters, M. D., Clinical Medicine and Prosector of Anatomy; Louis Augspurgh, D. D. S., Oral Surgery; W. U. Simons, U. S. Signal Service, Meteorology, etc.

The fifth annual course will begin October 3, 1883, and continue five months.

The requirements for graduation are the ordinary ones.

Fees.—Professors' tickets, $50; matriculation, $5; demonstrator's ticket, $5; hospital ticket, $5; graduation, $25.

Address R. G. Jennings, M. D., Secretary, Little Rock, Ark.

California.

COOPER MEDICAL COLLEGE, SAN FRANCISCO, CAL.

This college is the successor to the Medical College of the Pacific.

Faculty.—Henry Gibbons, M. D., Principles and Practice of Medicine; L. C. Lane, M. D. (President), Surgery; C. N. Ellinwood, M. D., Physiology; Adolph Barkan, M. D., Ophthalmology and Otolaryngology; J. H. Wythe, M. D., Microscopy and Histology; Henry Gibbons, Jr., M. D. (Dean), Obstetrics and Diseases of Women and Children; William A. Douglass, M. D., Clinical Surgery; J. O. Hirschfelder, M. D., Clinical Medicine; Clinton Cushing, M. D., Gynecology; W. D. Johnston, M. D., Chemistry and Toxicology; L. L. Dorf, M. D., Materia Medica and Therapeutics; R. H. Plemmor, M. D., Anatomy; John F. Morse, M. D. (Adjunct), Anatomy; W. S. Whitwell, M. D. (Adjunct), Obstetrics; Charles E. Farnum, M. D., Demonstrator of Anatomy.
The regular course begins in June of each year, and terminates in October. The intermediate course begins in January, and continues until the 1st of May.

Requirements for Graduation.—Attendance on three regular courses and two courses of clinical instruction; dissection of the entire cadaver; the other ordinary requirements. The college will comply with the requirements of the Illinois State Board of Health.

Fees.—Matriculation, $5; lectures, $130; Demonstrator’s ticket, $10.

Further information may be obtained from Henry Gibbons, Jr., M. D., Dean, 101 Dupont Street, San Francisco, Cal.

Canada.

McGILL UNIVERSITY, FACULTY OF MEDICINE, MONTREAL.

The following changes have been made in the teaching corps during the past year: Dr. James Stewart, of Brucefield, Ont., has succeeded Dr. Wright in the chair of materia medica and therapeutics; on the resignation of Dr. McCallum, the chair of obstetrics and diseases of women was divided, and Dr. A. A. Browne was made professor of obstetrics and Dr. William Gardner professor of gynaecology; Dr. F. J. Shepherd, the former demonstrator of anatomy, succeeds the late Dr. Scott as professor of anatomy; the lecturership in ophthalmology has been made a professorship; Dr. George Wilkins has been appointed professor of medical jurisprudence; Dr. R. L. Macdonnell becomes demonstrator of anatomy, with Dr. William Sutherland and Dr. R. J. B. Howard as assistants; Dr. Wesley Mills has been made demonstrator of practical physiology.

The course is so arranged as to divide the primary and final branches of study equally. In the first two sessions the student works at botany (first year), anatomy, physiology, chemistry, and materia medica, and passes on these subjects. The third and fourth sessions are devoted entirely to final work. In the hospital the clinical classes are arranged into a junior (third) and senior (fourth) year, and the instruction is largely at the bedside. The most important feature of the teaching is the system of case-taking by the students, who examine the patient before the class and have their reports verified or corrected. Systematic practical instruction in gynaecology is given to fourth-year students at the University Dispensary in groups of two or three daily. Though attendance at only six cases of labor is necessary to qualify for examination, the majority of the candidates are able to present certificates of attendance upon from fifteen to twenty cases at the lying-in hospital. A practical course in obstetric operations is also given.

Special clinical instruction is given in ophthalmology, laryngology, diseases of children, and diseases of the skin. The post-mortems are performed by the senior students in rotation. None of the foregoing are extra courses, but all are embraced in the general instruction of the senior students. In this way a man devoting two years to the study of the practical branches of medicine gets a very fair knowledge of his profession, and, if diligent, may become familiar with the more essential features of the special departments.

During the year the faculty has raised an endowment of $100,000, the interest of which will be used in extending the practical teaching of the school.

Faculty.—John William Dawson, LL. D., F. R. S. (Principal), Natural History; William Wright, M. D., Materia Medica and Therapeutics (emeritus); Duncan C. McCallum, M. D., Midwifery and Diseases of Women (emeritus); Robert Craik, M. D. (treasurer), Chemistry (emeritus); Joseph Morley Drake, M. D., Institutes of Medicine (emeritus); R. Palmer Howard, M. D. (dean), Medicine; G. E. Fenwick, M. D., Surgery; G. P. Girdwood, M. D., Chemistry; George Ross, M. A., M. D., Clinical Medicine; William Osler, M. D. (registrar), Professor of the Institutes of Medicine; Thomas G. Roddick, M. D., Clinical Surgery; William Gardner, M. D., Gynaecology; Francis J. Shepherd, M. D., Anatomy; Frank Bulley, M. D., Ophthalmology and Otology; Arthur A. Browne, B. A., M. D., Midwifery and Diseases of Infancy; James Stewart, M. D., Materia Medica and Therapeutics; George Wilkins, M. D., Medical Jurisprudence; D. P. Penhallow, B. Sc., Botany; R. L. Macdonnell, B. A., M. D., Demonstrator of Anatomy and Lecturer on Hygiene; William R. Sutherland, M. D., Assistant Demonstrator and Curator; George W. Major, B. A., M. D., Instructor in Laryngology; Alexander D. Blackader, B. A., M. D., Instructor in Diseases of Children; T. Wesley Mills, M. A., M. D., Demonstrator of Practical Physiology and Histology; Robert J. B. Howard, B. A., M. D., Assistant Demonstrator of Anatomy.

The fifty-first annual session opens Monday, October 1, 1883, and lasts six months. Students from the United States must pass the university matriculation examination (English Language; English History; Modern Geography; Latin, including Translation from the original and Grammar; Elements of Mathematics, comprising [a] Arithmetic, including Vulgar and Decimal Fractions; [b] Algebra, including Simple Equations; [c] Geometry, including the first two books of Euclid or the subjects thereof; Elementary Mechanics of Solids and Fluids; one of the following optional subjects: Greek, French, German, Italian, or some other modern language, Logic, Botany, Elementary Chemistry), unless they have already passed the matriculation examination of a recognized university.

Requirements for Graduation.—Attendance on four months’ sessions in this or some other recognized school, or four years’ study, including three such courses; eighteen months of attendance at a hospital approved of by the university; six months’ practice in pharmacy; three months’ attendance at an approved lying-in hospital, including the care of six cases of labor. The other requirements are substantially the same as in the larger colleges of the United States.

Fees.—First year, $79; second year, $92; third year, $75; fourth year, $65; hospital fees, $28; graduation, $30; university matriculation, $5.

This college has signified its intention of conforming to the requirements of the Illinois State Board of Health.
TORONTO SCHOOL OF MEDICINE.

Faculty.—W. T. Aikins, M. D., LL. D., Principles and Practice of Surgery and Clinical Surgery; H. H. Wright, M. D., L. C. P. & S., U. C. (Secretary), Principles and Practice of Medicine and Clinical Medicine; J. H. Richardson, M. D., M. R. C. S. Eng., Descriptive Anatomy; Uzzell Oden, M. D., Midwifery and Diseases of Women and Children; James Thorburn, M. D., Edin. and Toronto Univ., Materia Medica and Therapeutics; M. Barrett, M. D., Physiology; W. W. Oden, M. B., Midwifery (adjunct) and Medical Jurisprudence and Toxicology; M. H. Aikins, M. B., M. R. C. S. Eng., Surgery (adjunct) and Primary Anatomy; W. Oldbright, M. D., Medical Jurisprudence (adjunct) and Sanitary Science; L. McFarlane, M. B., Anatomy (adjunct) and Demonstrator of Anatomy; George Wright, M. B., Materia Medica and Therapeutics (adjunct); J. E. Graham, M. D., L. R. C. P. Lond., Practice of Medicine (adjunct) and Clinical Medicine and Dermatology and Pathology; R. A. Reeve, M. D., Diseases of the Eye and Ear; Thomas Heyes, Chemistry; Henry Montgomery, B. Sc., Botany and Zoology; A. H. Wright, M. B., M. R. C. S. Eng., Demonstrator of Normal Histology; John Ferguson, M. B., L. F. P. S. Glasgow, Assistant Demonstrator of Anatomy.

The forty-first session opens Monday, October 1, 1883, and lasts until April 1, 1884.

The requirements for graduation and the fees do not differ materially from those of the Royal College of Physicians and Surgeons at Kingston, although there are many minor points of difference, which we have not space to specify. The school will conform to the requirements of the Illinois State Board of Health. Address Dr. H. H. Wright, Secretary, corner of Sherbourne and Gerrard Streets, Toronto.

ROYAL COLLEGE OF PHYSICIANS AND SURGEONS,
KINGSTON, CANADA.

The thirtieth session begins the first Wednesday in October, and lasts six months.

Requirements for Graduation.—All but graduates or matriculates of a recognized university, and matriculates of the Medical Council of Ontario, must pass the matriculation examination of Queen's College. Candidates must have studied medicine four years, including three years at college; they must have attended twenty-five lectures in microscopic anatomy and sanitary science, one course of three months in practical chemistry and botany, two courses of three months in clinical surgery, clinical medicine, and medical jurisprudence, and two courses of six months in the other branches, besides eighteen months of hospital practice. A practical experience in pharmacy and in midwifery also is required. There are three examinations at different periods.

Fees.—Registration, $5; the different courses, $4 to $12; each examination, $10.

The college will comply with the requirements of the Illinois State Board of Health.

HALIFAX MEDICAL COLLEGE,
HALIFAX, N. S.

Lecturers.—E. Jennings, M. D., Dermatology; T. R. Almon, M. D., Diseases of Children; D. Dew, Harrington, M. D., Medical Jurisprudence; W. T. Ross, F. R. C. S. Ireland, Ophthalmology and Otology.

Instructors.—Mr. W. H. Waddell, Practical Chemistry; A. W. H. Lindsay, M. D., M. E. Eng., Microscopy; C. E. Puthner, Ph. M., Practical Pharmacy; Dr. Campbell and Dr. Lindsay, Demonstrators of Anatomy.

The seventeenth session will begin October 25, 1883. The regular order of lectures will begin October 29th, and will be continued six months.

The matriculation examination demanded is that of the Provincial Medical Board, and the following extracts from the "Nova Scotia Medical Act" are published for the information of students:

"7. Hereafter no person shall begin or enter upon the study of physic, surgery, or midwifery, for the purpose of qualifying himself to practice the same in this province, unless he shall have obtained from the Provincial Medical
Board a certificate showing that he has satisfactorily passed a matriculation or preliminary examination in the subjects specified in Schedule B of this act.

8. No candidate shall be admitted to such matriculation or preliminary examination unless he shall have, at least fourteen days previous to such examination, given notice to the registrar of the Provincial Medical Board of his intention to present himself for such examination, and transmitted to the registrar a certificate showing that he has completed his sixteenth year, and shall, before the examination, have paid a fee of $5 to the registrar."

Requirements for Graduation.—Four years' attendance at lectures, including two six months' courses in anatomy, chemistry, materia medica, physiology, principles and practice of surgery, obstetrics and diseases of women and children, principles and practice of medicine, practical anatomy, clinical medicine, and clinical surgery, and one three months' course in practical pharmacy, medical jurisprudence, botany, and practical chemistry; twelve months' attendance at an approved hospital; three months' practice in dispensing; six months' attendance at a lying-in hospital; a certificate from a registered practitioner of proficiency in the practice of vaccination. Besides the general oral and written examination, candidates are examined at the bedside. The general examination in the elementary branches takes place at the close of the second year, and in the other branches at the close of the fourth year.

Fees.—Medical jurisprudence, practical chemistry, practical pharmacy, microscopy, and botany tickets, $6 each; practical anatomy ticket, $8; other tickets, $12 each; registration, $2 (perpetual, $5). Address F. J. Black, M. D., Registrar, 49 Granville Street, Halifax, N. S.

FACULTY OF MEDICINE,
UNIVERSITY OF BISHOP'S COLLEGE,
MONTREAL.

The thirteenth session begins Tuesday, October 2, 1884, and continues until the end of March, 1885. A preliminary examination is required. Attendance on three sessions is obligatory, namely: First session.—Materia medica, botany, anatomy, physiology, chemistry, obstetrics, surgery, dissections, hospital practice. Second session.—Anatomy, physiology, chemistry, materia medica, therapeutics, medicine, gynecology, hygiene, practical chemistry, practical histology, dissections, hospital practice, clinical lectures. Third session.—Medicine, surgery, pathology, obstetrics, gynecology, therapeutics, medical jurisprudence, hospital practice, clinical lectures. Four years are advised, namely: First year.—Materia medica, botany, anatomy, physiology, chemistry, practical anatomy, hospital practice. Second year.—Anatomy, physiology, materia medica, therapeutics, hygiene, chemistry, practical chemistry, practical histology, surgery, gynecology, obstetrics, dissection, hospital practice, clinics. Third year.—Anatomy, therapeutics, physiology, medicine, medical jurisprudence, dissection, hospital practice, clinics. Fourth year.—Medicine, surgery, pathology, obstetrics, gynecology, medical jurisprudence, hospital practice, clinical lectures.

Requirements for Graduation.—Four years' study, including three courses of lectures. The examinations are oral and in writing. In the elementary branches students may be examined at the end of the second year, and in botany at the end of the first year.

Fees.—Separate tickets, $6 and $12; practical chemistry, $12; practical anatomy, $6; practical histology, $16; reenrollment, $2; hospital tickets and clinical lectures, $8 to $12. The foregoing are for one course. Graduation, $20.

This college will comply with the requirements of the Illinois State Board of Health. For further information address Dr. F. W. Campbell, Dean, 10 Phillips Place, Beaver Hall.

TRINITY MEDICAL SCHOOL,
TORONTO.

The winter session begins Tuesday, October 2d, and continues six months.

The requirements, etc., do not differ essentially from those of the other Canadian colleges. The school will con-
form to the requirements of the Illinois State Board of Health. Address Dr. Walter B. Geikie, Dean, 324 Jarvis Street, Toronto.

Colorado.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF DENVER.

Professor Short (chemistry) and Professor MacDonald (physiology) have resigned, and their chairs have been filled, respectively, by W. P. Headden, Ph. D., and J. H. Kimball, M. D. A lecturer on laryngoscopy and rhinology has been added.

Faculty.—H. K. Steele, M. D. (Dean), Principles and Practice of Surgery and Clinical Surgery; F. J. Bancroft, M. D., Clinical Surgery—Fractures and Dislocations; J. C. Davis, M. D., Operative Surgery and Surgical Pathology; H. A. Lemen, M. D., Principles and Practice of Medicine and Clinical Medicine; C. M. Parker, M. D., Clinical Medicine—Fever and General Diseases; W. H. Williams, M. D., Diseases of Women and Children; A. Stedman, M. D., Obstetrics and Puerperal Diseases; Charles Denison, M. D., Diseases of the Chest and Climatology; W. R. Whitehead, M. D., Anatomy; W. E. Wilson, M. D., Materia Medica and Therapeutics; J. H. Kimball, M. D. (Secretary), Physiology and Diseases of the Mind and Nervous System; J. W. Graham, M. D., Medical Jurisprudence; W. P. Headden, Ph. D., Chemistry; E. C. Rivers, M. D., Lecturer on Ophthalmology; H. H. Howland, M. D., Lecturer on Laryngoscopy and Rhinology; P. V. Carlin, M. D., Demonstrator of Anatomy.

The third annual session will begin October 2, 1883, and will close on the last Wednesday in March, 1884.

Applicants for admission are expected to pass a thorough examination in English composition, writing, grammar, arithmetic, natural philosophy, and rudiments of Latin; but all applicants holding the degree of A. B., or a diploma from any high school, or a certificate of proficiency in the above-named branches, from a reputable teacher of such school, shall be considered sufficiently prepared.

Requirements for Graduation.—Besides the usual requirements, practical anatomy and chemistry during two sessions.

Fees.—Matriculation, $5; lecture course, $75; laboratory fees, $10; dissection, $5; graduation, $30.

The college complies with the requirements of the Illinois State Board of Health. Address Professor H. K. Steele, Dean, Denver, Col.

Connecticut.

MEDICAL DEPARTMENT OF YALE COLLEGE, NEW HAVEN, CONN.

The only noteworthy changes in the faculty during the year have been the transfer of Professor Lindley to the chair of practice, in place of the late Professor Wilcox, and the appointment of Dr. T. H. Russell to the chair of materia medica, etc., made vacant by the transfer.

Faculty.—Benjamin Silliman, M. D., Chemistry; Moses C. White, M. D., Pathology; C. A. Lindsay, M. D. (Dean), Theory and Practice of Medicine; Leonard J. Sanford, M. D., Anatomy; William H. Carmalt, M. D., Surgery; James K. Thacher, M. D., Physiology; T. H. Russell, M. D., Materia Medica and Therapeutics; Frank E. Beckwith, M. D., Obstetrics and Diseases of Women and Children.

Lecturers.—William O. Ayres, M. D., Nervous Diseases; Henry P. Searns, M. D., Insanity; S. Hartwell Chapman, M. D., Diseases of the Throat and Ear; Samuel B. St. John, M. D., Ophthalmology; William H. Hotchkiss, M. D., Demonstrator of Anatomy; T. Mitchell Prudden, M. D., Normal Histology; Henry Fleischner, M. D., Dermatology; Herbert E. Smith, M. D., Chemistry.

The first term of the seventy-first annual session begins October 4th, and closes December 19th; the second term begins January 10, 1884, and ends April 3d; the third term lasts from April 11th to June 26th.

The system of instruction embraces a three years' graded course. A preliminary examination is required of those who have not a degree in letters or science from a recognized institution, or have not passed the examination for admission to Yale College. The next preliminary examination will be held October 3d. The gradation of studies is as follows: First year, chemistry, anatomy, histology; second year, anatomy, physiology, materia medica and therapeutics, practice of medicine, clinical medicine, obstetrics, surgery, and clinical surgery; third year, pathology, theory and practice of medicine, physical diagnosis, clinical medicine, surgery, clinical surgery, obstetrics, diseases of women and children, ophthalmology, medical jurisprudence, insanity, diseases of the throat and ear, nervous diseases, venereal diseases, diseases of the skin.

Requirements for Graduation.—At least one continuous year at the school and an examination in all the studies of the three years' course. No Thesis is required. Examinations at the close of each year.

Fees.—Matriculation, $5; each year's tuition, $125; graduation, $30.

The school complies with the requirements of the Illinois State Board of Health. Address Professor C. A. Lindsay, Dean.

District of Columbia.

NATIONAL MEDICAL COLLEGE (MEDICAL DEPARTMENT OF COLUMBIAN UNIVERSITY), WASHINGTON.

Faculty.—A. Y. P. Garstett, M. D. (President), Clinical Medicine (emeritus); Grafton Tyler, M. D., Theory and Practice of Medicine (emeritus); N. S. Lincoln, M. D., Surgery (emeritus); J. Ford Thompson, M. D., Surgery; W. W. Johnston, M. D., Theory and Practice of Medicine; A. F. A. King, M. D. (Dean), Obstetrics and the Diseases of Women and Children; Edward T. Frisoe, L. L. D., Chemistry and Toxicology; William Lee, M. D., Physiology; Elliott Couris, M. D., Ph. D., Anatomy; D. Webster Prentiss, M. D., Materia Medica and Therapeutics;
THE STUDENTS' NUMBER.

John R. Hamilton, M. D., Lecturer on Surgery; A. C. Adams, M. D., Demonstrator of Anatomy; G. N. Acker, M. D., Demonstrator of Practical Physiology and Pathological Histology; Leon L. Friedrich, M. D., Assistant Demonstrator of Anatomy and Prosector in Anatomy; W. P. Lawver, M. D., Demonstrator of Practical Chemistry.

The sixty-second course will begin October 1, 1883, and continue until March 1, 1884.

Requirements for Graduation.—Candidates must have attended three courses of lectures, the subjects to be arranged as follows: First course, anatomy, physiology, chemistry, materia medica, practical anatomy, and histology; second course, anatomy, physiology, chemistry, materia medica, practice of medicine, surgery, and obstetrics, histology, practical anatomy, clinics (examination at the end of second course in anatomy, physiology, chemistry, and materia medica); third course, practice of medicine, surgery, obstetrics, pathological histology, clinical medicine, and surgery (final examination at the end of this course). Dissection of "two parts." The other requirements as usual.

Fees.—Full course of lectures, $100; single tickets, $15; practical anatomy, $10; matriculation, $5; examination fee, primary branches, $20; examination fee, final branches, $10.

Address A. F. A. King, M. D., Dean, 726 Thirteenth Street, Washington, D. C.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF GEORGETOWN, D. C.

The following changes have taken place in the corps of professors: Emeritus Professor Noble Young, M. D. (President), Principles and Practice of Medicine, and Professor F. A. Ashford, M. D., Surgery, and Dean and Treasurer, have been removed by death. J. W. H. Lovejoy, M. D., has been appointed to the chair of Theory and Practice of Medicine, and also made Dean and Treasurer. J. S. Beale, M. D., has been appointed to the chair of Surgery, and Frank Baker, M. D., succeeds the latter in the chair of Anatomy. Joseph Taber Johnson, M. D., has been elected President of the Faculty. G. L. Magruder, M. D., has been appointed to the chair of Materia Medica and Therapeutics, and Louis Kolipinski, M. D., has been made Demonstrator of Anatomy.

The titles of the lectureships held by Dr. S. M. Burnett and Dr. E. C. Morgan have been changed, and they are now termed, respectively, Clinical Professor of Ophthalmology and Otology, and Clinical Professor of Laryngology.

Faculty.—Flodardo Howard, M. D. (emeritus), Obstetrics and Diseases of Women and Infants; Johnson Eliot, M. D. (emeritus), Surgery and Clinical Surgery; James E. Morgan, M. D. (emeritus), Materia Medica, Therapeutics, and Medical Jurisprudence; Thomas Antisell, M. D. (emeritus), Chemistry and Toxicology; Samuel C.

Bussey, M. D. (emeritus), Theory and Practice of Medicine and Clinical Medicine; Joseph Taber Johnson, M. D. (President), Obstetrics and Diseases of Women and Infants; Carl H. A. Kleinschmidt, M. D., Physiology; James S. Beale, M. D., Surgery; J. W. H. Lovejoy, M. D. (Dean), Theory and Practice of Medicine; M. G. Elzey, M. D., Chemistry and Toxicology; Frank Baker, M. D., Anatomy; G. L. Magruder, M. D., Materia Medica and Therapeutics; Swan M. Burnett, M. D., Ophthalmology and Otology (clinical); Ethelbert C. Morgan, M. D., Laryngology (clinical); Thomas E. McCord, M. D., Lecturer on Venereal Diseases; Samuel S. Adams, M. D., Lecturer on Diseases of Children; Louis Kolipinski, M. D., Demonstrator of Anatomy.

The regular course began Monday, September 3, 1883, and will continue until May 1, 1884. Lectures are delivered daily, beginning at 5:30 p.m., in order to accommodate those who are employed in governmental departments.

Requirements for Graduation.—In addition to the usual requirements, two courses of practical anatomy and two courses of clinical instruction.

Fees.—Lectures, $100; matriculation, $5; demonstrator, $10.

No graduation fee is required of students who have paid for three courses in this college, but $30 will be charged to those credited courses in other schools. Single tickets, $15.

For further information apply to J. W. H. Lovejoy, M. D., Dean. No. 900 Twelfth Street, N. W., Washington, D. C.

MEDICAL DEPARTMENT OF HOWARD UNIVERSITY, Washington.

Faculty.—Thomas B. Hood, M. D. (Dean), Principles and Practice of Medicine; Charles B. Purvis, M. D. (Secretary), Obstetrics and Diseases of Women and Children; Niel P. Graham, M. D., Principles and Practice of Surgery; Daniel S. Lamb, M. D., Descriptive and Surgical Anatomy; William H. Seaman, M. D., Chemistry; John E. Brackett, M. D., Materia Medica and Therapeutics; Robert Reubens, M. D., Physiology and Medical Jurisprudence; N. Whitcomb, D. D. S., Dental Surgery and Operative Dentistry; ———, D. D. S., Dental Mechanism and Metallurgy; Clarence R. DuFour, Ph. D., Pharmacy and Botany; E. A. Balloch, M. D., Demonstrator of Anatomy; M. G. Jensen, M. D., D. D. S., Demonstrator in Dentistry.

The sixteenth annual session will begin October 1, 1883, and continue five months.

Applicants for admission must pass an examination in the ordinary English branches and possess a sufficient knowledge of the Latin language to read and write prescriptions and understand medical terms. This college is open to all without regard to sex or race.

Requirements for Graduation.—Applicants shall have attended three courses of lectures at some regular medical college, the last at this school; shall have complied with the regulations of the school in regard to clinical lectures,
dissections, etc.; shall pass the required examinations, and present an acceptable dissertation upon some subject of original observation.

FEES.—Matriculation, $10; dissection, $5; incidental expenses, $20; graduation, $30.

The school complies with the requirements of the Illinois State Board of Health. Address Charles B. Purvis, M. D., Secretary, No. 1118 Thirteenth Street, N. W., Washington, D. C.

--

ATLANTA MEDICAL COLLEGE,
ATLANTA, GA.

FACULTY.—A. W. Griggs, M. D., Practice (emeritus); W. F. Westmoreland, M. D., Principles and Practice of Surgery; Wm. Abram Love, M. D., Physiology; V. H. Talliaferro, M. D., Obstetrics and Diseases of Women and Children; A. W. Calhoun, M. D., Diseases of the Eye, Ear, and Throat; J. H. Logan, M. D., Chemistry; H. V. Miller, M. D., LL. D. (Dean), Principles and Practice of Medicine, Lecturer on Clinical Medicine; W. S. Armstrong, M. D., Anatomy, Lecturer on Clinical Medicine; J. S. Todd, M. D., Materia Medica and Therapeutics, Lecturer on Clinical Medicine; James A. Gray, M. D. (Proctor), Lecturer on Venereal Diseases; D. H. Howell, M. D., Lecturer on Minor Surgery; C. F. Benson, Jr., M. D., Demonstrator of Anatomy; R. O. Cotter, M. D., Assistant in Eye, Ear, and Throat Diseases.

The twenty-sixth annual course of lectures will begin on the 11th of October, 1883, and close on the 1st of March, 1884.

This is the opening of the regular session. Owing to the lengthening of the course of lectures, the preliminary course has been dispensed with.

REQUIREMENTS FOR GRADUATION.—Not peculiar.

FEES.—Full course, $75; practical anatomy, $10; matriculation, $5; graduation, $30. Gratutious tickets (not including matriculation, practical anatomy, or graduation) will be issued to one student from each congressional district of the State, in compliance with the law making a donation to the building and apparatus of the college.

For further information address James A. Gray, M. D., Proctor, Atlanta, Ga.

--

SOUTHERN MEDICAL COLLEGE,
ATLANTA, GA.

Professor W. G. Owen has resigned the chair of practice and has been elected emeritus professor. W. D. Bizzell, M. D., late of the chair of chemistry, succeeds Professor Owen, and Professor J. A. Burns has been appointed to the chair of chemistry.

FACULTY.—W. G. Owen, M. D., Principles and Practice of Medicine (emeritus); T. S. Powell, M. D., Obstetrics and Diseases of Women and Children, and Lecturer on Medical Ethics; R. C. Word, M. D., Physiology and Lecturer on Hygiene; G. G. Crawford, M. D., Operative and Clinical Surgery; W. Perrin Nicolson, M. D. (Dean), Descriptive and Special Anatomy; John T. Johnson, M. D., Principles and Practice of Surgery; G. G. Roy, M. D., Materia Medica and Therapeutics, and Lecturer on Toxicology; A. G. Hobbs, M. D., Diseases of the Eye, Ear, and Throat; W. D. Bizzell, M. D., Principles and Practice of Medicine; J. A. Burns, Chemistry.

AUXILIARY PROFESSORS AND SPECIAL LECTURERS.—J. F. Alexander, M. D., Practice of Medicine, and Lecturer on Clinical Medicine; B. H. Catching, D. D. S., Lecturer on Dental Surgery.

The fifth annual course will begin October 9, 1883, and continue until February 29, 1884.

REQUIREMENTS FOR GRADUATION.—Besides the usual requirements, dissection is obligatory.

FEES.—Matriculation, $5; full course, $75; demonstrator's fee, $10; graduation, $30.

For further information address W. Perrin Nicolson, M. D., Dean, P. O. Box 234, Atlanta, Ga.

--

RUSH MEDICAL COLLEGE,
CHICAGO.

During the year Dr. Roswell Park has resigned the lecturership of surgery, and his place has been supplied by the appointment of Dr. William T. Belfield. As has already been stated in this journal, the college is now building a hospital. For the first time, there is to be a preliminary examination this year, and we are informed that its prospective enforcement is drawing a superior class of pupils to the college.

FACULTY.—J. Adams Allen, M. D., LL. D. (President), Principles and Practice of Medicine; DeLaskie Miller, Ph. D., M. D., Obstetrics and Diseases of Children; Moses Gunn, M. D., LL. D., Principles and Practice of Surgery and Clinical Surgery; Joseph P. Ross, M. D., Clinical Medicine and Diseases of the Chest; William H. Byford, M. D., Gynecology; Edward L. Holmes, M. D., Diseases of the Eye and Ear; Henry M. Lyman, M. D., Physiology and Diseases of the Nervous System; James H. Etheredge, M. D. (Secretary), Materia Medica and Medical Jurisprudence; Charles T. Parkes, M. D., Anatomy; Walter S. Haines, M. D., Chemistry, Pharmacy, and Toxicology; James Nevins Hyde, M. D., Skin and Venereal Diseases; Norman Bridge, M. D., Hygiene and (Adjunct) Principles and Practice of Medicine.

ADJUNCT PROFESSORS AND LECTURERS.—J. Suidam Knox, M. D., Diseases of Children and Obstetrics; Daniel T. Nelson, M. D., Philip Adolphus, M. D., Gynecology; Albert B. Strong, M. D. (Demonstrator), Anatomy; Lafayette W. Case, M. D., Dermatology; William T. Belfield, M. D., Physiology and Pathology; Eugene W. Whitney, M. D., Surgical Dressings and (Demonstrator) Surgery; Alfred C. Cotton, M. D., Materia Medica and Therapeutics; Eugene S. Talbot, M. D., D. D. S., Dental Anatomy and Physiology; Samuel J. Holmes, M. D., Pathological Anato-
my and Histology; Daniel R. Brower, M. D., Practice of Medicine; H. P. Merriman, M. D., Gynaeceology; John A. Robison, M. D., Assistant in Clinical Medicine; Lewis L. McArthur, M. D., William H. Taylor, M. D., Cassius D. Westcott, M. D., Demonstrators of Chemistry; Frederick E. Sherman, M. D., Thomas J. Shaw, M. D., Assistant Demonstrators of Anatomy; Edward P. Davis, M. D., Demonstrator of Physiology and Prosector in Surgery; William H. Morgan, M. D., Clinical Assistant in Diseases of Children.

The forty-first annual session begins September 25th, and continues twenty-one weeks.

A gradation of study is recommended and provided for, and those graduated after a three years' course receive a certificate of honor. Instruction in dentistry is included in the curriculum.

Requirements for Graduation.—Two terms of clinical instruction, dissection of every region of the body, one course in practical chemistry, and the usual requirements in addition. Students who enter for three full winter terms may have their final examinations in descriptive anatomy, physiology, chemistry, materia medica, and therapeutics at the close of the second winter term.

Fees.—Matriculation (annual), $5; course of lectures, $75; dissection, $5; practical chemistry, $5; final examination, $50. Anatomical and chemical material "at cost price."

The college will comply with the requirements of the Illinois State Board of Health. Address Professor James H. Etheridge, Secretary, 1634 Michigan Avenue, Chicago.

COLLEGE OF PHYSICIANS AND SURGEONS,
of CHICAGO, ILL.

Professor W. E. Quine succeeds Dr. Carpenter in the chair of practice of medicine. Professor W. K. Harrison succeeds Dr. McCoy in the chair of medical chemistry, and Dr. R. W. Hall succeeds Dr. Power as demonstrator of anatomy. Dr. Burnett has resigned the lecturership on surgical anatomy.

The winter session will begin September 25, 1883, and will continue twenty-four weeks. In the absence of a literary certificate, a preliminary examination is enforced. The requirements for graduation are as usual.

Fees.—Matriculation (paid annually), $5; general ticket, admitting to all the lectures, and including all practical work in the chemical and physiological laboratories, $50; from alumni of this college, and from its students who have taken and paid for two full courses of lectures, the matriculation fee only ($5) will be expected; from alumni of other regular medical colleges, the matriculation fee and one half lecture fee will be required; dissecting ticket (each session), including dissecting material, $10; graduation, $30; tickets for Cook County Hospital (good till the following March) and for the Eye and Ear Infirmary—good for one year, each, $5.

The college complies with the requirements of the Illinois State Board of Health.

Address D. A. K. Steele, M. D., Secretary, 1801 State Street, Chicago, Ill.

WOMAN'S MEDICAL COLLEGE,
of CHICAGO, ILL.

Faculty.—W. Godfrey Dys, M. D., F. R. C. S., Theory and Practice of Medicine (emeritus); G. C. Paoli, M. D., Materia Medica and Therapeutics (emeritus); T. Davis Fitch, M. D., Gynaeceology (emeritus); William H. Byford, M. D. (President), Gynaeceology; Charles Warrington Earle, M. D. (Treasurer), Diseases of Children and Clinical Medicine; Isaac N. Danforth, M. D., Pathology and Renal Diseases; Henry M. Lyman, M. D., Theory and Practice of Medicine; Daniel R. Brower, M. D., Diseases of the Nervous System, Medical Jurisprudence, and Clinical Medicine; Sarah Hackett Stevenson, M. D., Obstetrics; David W. Graham, M. D. (Secretary), Surgery; Plym S. Hayes, M. D., Chemistry and Toxicology; W. J. Maynard, M. D., Dermatology; W. T. Montgomery, M. D., Ophthalmology and Otology; E. Fletcher Ingrals, M. D., Diseases of the Chest and Throat; F. L. Wadsworth, M. D., Physiolo-

ogy and Histology; Marie J. Mergler, M. D. (Associate), Gynaeceology; Walter L. Dorland, M. D., Materia Medica and Therapeutics; Mary E. Bates, M. D., Lecturer on Anatomy; Eugene S. Talbot, M. D., D. D. S., Dental Surgery; John O. Hobbs, M. D., Demonstrator of Anatomy; Jennie E. Hayner, M. D., Lecturer on Hygiene; Robert S. Hall, M. D., Clinical Lecturer on Midwifery; Emma M.
Nichols, M. D., Assistant in Physiology and Lecturer on Histology; Homer N. Thomas, M. D., Assistant in Diseases of the Chest and Throat; Eliza H. Root, M. D., Isabel R. Copp, M. D., Assistants in Clinical Medicine; Annette S. Dobbins, M. D., Assistant Demonstrator of Anatomy.

The fourteenth annual course of instruction will begin September 18, 1888, and will close April 22, 1884.

Students must present satisfactory proof of a good English education before matriculating. Certificates of graduation from a high school, or like institution, or a teacher's certificate from a county superintendent of schools, will be accepted as sufficient evidence of such education.

Requirements for Graduation.—A candidate must have taken two courses in practical anatomy, and dissected each of the usual divisions of the subject at least once; and must have taken one course in practical chemistry and one course in hospital clinical instruction. This final examination must be, at least in part, in writing, which will be in lieu of the thesis heretofore required.

Fees.—Matriculation, annually, $8; general ticket, $50; demonstrator's ticket, $8; chemical laboratory ticket, required but once, $5; graduation, $30.

The college complies with the requirements of the Illinois State Board of Health.

Address D. W. Graham, Secretary, 101 Warren Avenue, Chicago, Ill.

QUINCY COLLEGE OF MEDICINE
(MEDICAL DEPARTMENT OF CHADDOCK COLLEGE),
QUINCY, ILL.

Faculty.—C. R. S. Curtis, M. D. (Dean), Principles and Practice of Surgery; M. F. Bassett, M. D., Principles and Practice of Medicine; Virgil McDavid, M. D., Obstetrics and Diseases of Women; William A. Byrd, M. D., Clinical Surgery; L. H. Cohen, M. D., Chemistry and Toxicology; Henry Hatch, M. D. (Registrar), Anatomy and Clinical Medicine; R. Woods, M. D., Diseases of the Eye and Ear; Carey B. Ellis, M. D., Physiology and Hygiene; M. Rooney, M. D., Clinical Medicine; Hugo Ercuson, M. D., Diseases of the Mind and Nervous System; (vacancy), Materia Medica and Therapeutics; George Carley, Ph. D., Pharmacy; D. Bryan Baker, M. D., Demonstrator of Anatomy.

The second annual course begins October 8, 1883, and ends toward the close of March, 1884.

All applicants must present evidence of a good English education.

First course pupils will be examined on and be expected to give especial attention to anatomy, physiology, chemistry, and materia medica. Second and third course students will be particularly examined in the practical branches.

Requirements for Graduation.—Two courses of dissection, in addition to the usual requirements.

Fees.—Matriculation, $8; professors' tickets, $40; demonstrator's ticket, $10; examination, $25.

The college complies with the requirements of the Illinois State Board of Health.

Address C. R. S. Curtis, M. D., Dean, or Henry Hatch, M. D., Registrar, Quincy, Ill.

Indiana.

MEDICAL COLLEGE OF EVANSVILLE,
EVANSVILLE, IND.

Faculty.—M. J. Bray, M. D., Clinical Surgery (emeritus); H. G. Jones, M. D. (Dean), Principles and Practice of Medicine; P. W. Achilles, M. D. (Secretary), Chemistry and Toxicology; P. Y. McCoy, M. D., Principles and Practice of Surgery; George Hodson, M. D., Obstetrics; Edwin Walker, M. D., Diseases of Women and Diseases of the Nervous System; J. O. Stillson, M. D., Physiology and Diseases of the Eye, Ear, and Throat; C. E. Lining, M. D., Materia Medica and Therapeutics; E. Linticum, M. D., Genito-Urinary and Venerable Diseases, and Clinical Surgery; W. R. McMahen, M. D., Huntingburg, Ind., Surgical Pathology; L. D. Brose, M. D., Anatomy; G. C. Perdue, M. D., Lecturer on Diseases of the Skin; J. C. McClurken, M. D., Adjunct Professor of Physiology and Histology; Jacob H. Keth, M. D., Demonstrator of Anatomy; W. F. Lavay, M. D., Assistant in Chemistry.

The eighteenth regular session will begin October 3, 1883, and continue until the last of February, 1884.

Requirements for Graduation.—In addition to the ordinary requirements, two courses of dissection and one in practical chemistry.

Fees.—Course of lectures, $40; matriculation, $8; demonstrator's fee, $5; graduation, $25.

Address Professor F. W. Achilles, Secretary, No. 14 Lower Third Street, Evansville, Ind.

FORT WAYNE COLLEGE OF MEDICINE,
FORT WAYNE, IND.

Dr. W. H. Bell has been elected to the chair of nervous and mental diseases, and Dr. A. E. VanBuskirk to the chair of anatomy. Professor Gobrecht and Dr. Finnimore have resigned, and Dr. J. V. Lewis has been elected to the chair of materia medica, made vacant by the resignation of Dr. Finnimore. Women are admitted.

Faculty.—R. W. Thrift, M. D., Puerperal Diseases and Diseases of Children (emeritus); Christian B. Stemen, M. D. (Dean), Surgery and Clinical Surgery; James S. Greg, M. D., Surgery and Clinical Surgery; George W. McCasky, Ph. B., M. D., Theory and Practice of Medicine and Clinical Medicine; I. Ellis Lyons, M. D., Obstetrics; Kent K. Wheelock, M. D., Physiology and Clinical Medicine; Charles R. Dryer, M. D., Chemistry and Toxicology; A. E. VanBuskirk, M. D., Anatomy and Clinical Surgery; James V. Lewis, M. D., Materia Medica and Therapeutics; F. W. Entikis, M. D., Diseases of Women; Norman Teal, M. D., Orthopaedic Surgery and Clinical Surgery; William Scott, M. D., Diseases of the Throat and Respiratory Organs; J. H. Kellogg, M. D., Sanitary Science and Hygiene; W. H.Bell, M. D., Nervous and Mental Diseases; Hon. Joseph K. Engerton, Lecturer on Medical Jurisprudence; J. T. Woods, M. D., Lecturer on General Fractures; G. B. Stemen, M. D., Assistant in the Chemical Laboratory; G. N. Worley, M. D., Lecturer on
Laryngology; M. E. Renner, M. D., Adjunct Professor of Physiology.

The fifth annual session began September 11th, and will close March 1st.

Requirements for Graduation.—Dissection for one session, practical instruction in chemistry, and hospital attendance, besides the usual requirements. The average on monthly examinations affects the candidate's final standing.

Fees.—Matriculation, $5; course of lectures, $40; dissection, $5; laboratory, $5; hospital, $5; graduation, $25.

Address Professor C. B. Stemen, Dean, 66 Calhoun Street, Fort Wayne, Ind.

CENTRAL COLLEGE OF PHYSICIANS AND SURGEONS,
INDIANAPOLIS, IND.

Faculty.—Charles D. Pearson, M. D., Diseases of the Nervous System; W. S. Haymond, M. D. (Dean), Principles and Practice of Surgery; John Moffett, M. D., Obstetrics; R. E. Haughton, M. D., Surgical Pathology, Operative and Clinical Surgery; G. C. Smythe, M. D., Principles and Practice of Medicine and Sanitary Sciences; Joseph Eastman, M. D. (Secretary), Diseases of Women and Clinical Surgery; George N. Ducas, M. D., Physiology and Clinical Medicine; R. French Stone, M. D., Materia Medica and Therapeutics, and Clinical Medicine; Ira A. E. Lyons, M. D., Diseases of the Eye and Ear; John A. Scrcliffe, A. M., M. D., Anatomy and Genito-Urinary Diseases; Philip S. Baker, A. M., M. D., Chemistry and Toxicology; W. H. Thomas, M. D., Demonstrator of Anatomy and Lecturer on Osteology; J. I. Rooker, M. D., Lecturer on Physical Diagnosis; the Hon. John Coburn, Lecturer on Medical Jurisprudence; J. T. Barker, M. D., Lecturer on Physiology; S. E. Earp, M. S., M. D., Demonstrator of Chemistry; Canada Button, M. D., Prosector to the Chair of Anatomy; John B. Long, M. D., Assistant Demonstrator of Anatomy.

The preliminary course will begin Wednesday, September 26, 1883, and continue till the commencement of the regular session, which begins Wednesday, October 3, 1883, and continues till March 1, 1884.

A preliminary examination is required of all who do not present evidence of a good English education. The voluntary three years' course is graded as follows: First year, anatomy (including dissections), histology, physiology, general chemistry; second year, anatomy (practical and surgical), medical chemistry, materia medica and therapeutics, minor surgery, and clinical medicine and surgery; third year, principles and practice of medicine, obstetrics and gynecology, surgery, ophthalmology and otorlgy, clinical medicine and surgery. Students who enter the graded course will be entitled to an examination at the end of each regular session, and those passing a satisfactory examination to a certificate. No other examination will be required of them.

Requirements for Graduation.—These include dissection.

Fees.—Matriculation, $5; laboratory ticket, $5; professors' tickets, $40; demonstrator's ticket, $5; hospital tickets, $6; graduation, $25.

Address W. S. Haymond, M. D., Dean, 42 East Ohio Street, Indianapolis, Ind.

IOWA.

COLLEGE OF PHYSICIANS AND SURGEONS,
KEOKEK, IOWA.

Faculty.—J. C. Hughes, M. D. (Dean), Institutes and Practice of Surgery and Surgical Clinics; John North, M. D., Ph. C., Chemistry, Toxicology, and Materia Medica; George F. Jenkins, M. D., Principles and Practice of Medicine and Medical Clinics; J. A. Schroes, M. D., Obstetrics and Diseases of Women; George M. Kellogg, M. D., Anatomy and Demonstrator of Anatomy; A. G. Field, M. D., Physiology, Pathology, General Therapeutics, and Public Hygiene; H. B. Young, M. D., Lecturer on Ophthalmology and Otology; M. R. King, Lecturer on Medical Jurisprudence; R. Heiser, Taxidermist and Curator.

The forty-third regular session will open October 10, 1883, and continue twenty weeks.

A certificate of graduation from a literary college, academy, high school, or first-class teacher's certificate, or a matriculation examination in the branches of a good English education is required for admission. Women are admitted.

Requirements for Graduation.—Two courses in dissection. No Thesis is required. The other requirements are usual.

Fees.—For the entire course of instruction, $20; matriculation, $5; demonstrator's ticket, $5; graduation, $30. Further information can be obtained from J. C. Hughes, M. D., Dean, Keokuk, Iowa.

MEDICAL DEPARTMENT OF THE
STATE UNIVERSITY OF IOWA,
IOWA CITY.

The fourteenth annual course of lectures will begin October 3, 1883, and close March 5, 1884.

A preliminary examination will be required of all students entering the first year, and also of those from other colleges which require no preliminary examination.

Faculty.—Gustavus Hinrichs, M. D., Chemistry and Toxicology; W. F. Peck, M. D., Surgery and Clinical Surgery; P. J. Farnsworth, M. D., Materia Medica and Diseases of Children; W. S. Robertson, M. D., Theory and Practice of Medicine, and Clinical Medicine; J. C. Shradar, M. D., Obstetrics and Diseases of Women; W. D. Middleton, M. D., Physiology and Microscopic Anatomy; Elmer F. Clapp, M. D., Anatomy; James M. Love, LL. D., Medical Jurisprudence; C. M. Antony, M. D., Lecturer on Ophthalmology and Otology, Demonstrator of Anatomy, and Curator of the Museum; O. T. Gillette, M. D. (Secretary), Assistant in Surgery; S. S. Lytle, M. D., Prosector in Anatomy.

Requirements for Graduation.—The usual requirements. Those taking the graded course are not required to furnish certificate of time of study.

Fees.—Lectures for yearly session, $20; matriculation
THE IOWA COLLEGE OF PHYSICIANS AND SURGEONS,
DE SCHOOLS,
Faculty.—J. A. Blanchard, M. D. (Dean), Principles and Practice of Medicine; A. C. Simonton, M. D., Principles and Practice of Surgery, and Clinical Surgery; J. F. Kennedy, A. M., M. D. (Secretary), Obstetrics and Clinical Diseases of Children; Lewis Schooler, M. D., Anatomy, General and Descriptive; L. C. Swift, M. D., Physiology, Clinical Pathology, and Hygiene; W. W. Hale, LL. B., M. D., Materia Medica and Therapeutics; W. H. Ward, M. D., Gynecology; T. E. Pope, A. M., Chemistry and Toxicology; C. M. Colvin, M. D., Diseases of Children, Orthopedic Surgery, and Clinical Medicine; Robert Mc
Nutt, A. M., M. D., Dermatology and Clinical Medicine; E. H. Hazen, M. D., Diseases of the Eye and Ear; F. E. Cuthenden, M. D., Diseases of the Throat and Nasal Pass-
gages; James T. Priestley, M. D., Clinical Surgery and Genito-Urinary Diseases; D. S. Fairchild, M. D., Pathology, Histology, and diseases of the Nervous System; the Hon. C. C. Nourse, Medical Jurisprudence.

The second annual session will commence September 25, 1883, and close March 5, 1884.

Requirements for Graduation.—Besides the usual requirements, satisfactory evidence of a preliminary education in the higher English branches, as taught in the high schools, academies, or literary colleges of this State, or be subjected to an examination in these branches, at the discretion of the faculty.

Undergraduates who elect a course of three annual sessions will be examined in anatomy, physiology, materia medica, and chemistry at the end of the second year or course, leaving the third year for special attention to the more practical branches.

Fees.—Matriculation (paid but once), $5; course of lectures, $40; demonstrator's ticket, $5; final examination fee, $25; material for dissection, at cost.

For further information address J. A. Blanchard, M. D., Dean, 410 Fourth Street, Des Moines, Iowa.

KENTUCKY SCHOOL OF MEDICINE,
LOUISVILLE, KY.

Faculty.—W. H. Watchen, M. D. (Dean), Obstetrics and Diseases of Women; Turner Anderson, M. D., Principles and Practice of Medicine and Diseases of Children; M. F. Coomes, M. D., Physiology and Diseases of the Eye, Ear, Throat, and Nose; C. W. Kelly, M. D. (Treasurer), Anatomy and Clinical Medicine; Henry Orensdorff, M. D., Materia Medica, Therapeutics, and Venereal Diseases; S. E. Woody, M. D., Medical Chemistry and Toxicology; Joseph M. Mathews, M. D., Surgical Pathology and Dis-

ences of the Rectum; J. M. Holloway, M. D., Surgery and Clinical Surgery; J. B. Marvin, B. S., M. D., Medical Microscopy and Nervous Diseases; H. Horace Grant, M. D., Lecturer on Operative and Minor Surgery; R. L. Thomson, M. D., Demonstrator of Anatomy.

A good English education is necessary to admission.

The preliminary course will begin January 7, 1884. The twenty-eighth annual course will begin February 10, 1884, and will continue twenty weeks. The graded system, which is optional, can be pursued as follows: First session, anatomy, physiology, and general chemistry; second session, materia medica, surgical pathology, medical chemistry, prac-
tice of medicine, clinical medicine, surgery, clinical surgery, and microscopy; third session, therapeutics, obstetrics and diseases of women, surgery and clinical surgery, practice of medicine, clinical medicine, and nervous diseases. Examinations on the studies of each grade are held at the end of each session, and official certificates of proficiency on the studies of each grade are given to those whose examinations have been satisfactory.

Requirements for Graduation.—The candidate must have dissected the several regions of the body; he must have attended clinical instruction in the City Hospital each year of attendance at the college. The other requirements are as usual.

Fees.—Matriculation, $5; professors' tickets, $75; dissection, $10; graduation, $30; clinical lectures at the City Hospital, $5.

Address W. H. Wathen, M. D., Dean, Fourth and Chestnut Streets, Louisville, Ky.

LOUISVILLE MEDICAL COLLEGE,
LOUISVILLE, KY.

Faculty.—C. W. Kelly, M. D. (Registrar), Descriptive and Surgical Anatomy and Clinical Medicine; J. A. Ireland, M. D. (Dean), Obstetrics and Gynecology; L. D. Kastenbtree, M. D., Chemistry and Urology; Terner Anderson, M. D., Materia Medica and Therapeutics; Edward Miller, M. D. (Secretary), Principles and Practice of Surgery; W. H. Galt, M. D., Principles and Practice of Medicine; James M. Holloway, M. D., Clinical and Operative Surgery; Samuel Cochran, M. D., Physiology.

Demonstrators.—Samuel Cochran, M. D., Anatomy; George M. Warner, M. D., Materia Medica and Practice of Medicine; H. B. Ritter, M. D., Obstetrics and Gynecology; William T. Carter, M. D., Diseases of Children.

A preliminary course began September 3d. The next regular session will commence October 1, 1883, and will terminate in the last week in February, 1884.

Requirements for Graduation.—Practical anatomy during one winter's session; one course of clinical instruction; in other respects, as usual.

Fees.—Matriculation, $5; professors' tickets, $75; demonstrator's ticket, $10; graduation, $30; clinical lectures at the Louisville City Hospital, $5.

Address Professor C. W. Kelly, Registrar, southeast corner Second and Green Streets, Louisville, Ky.

LOUISIANA
MEDICAL DEPARTMENT OF THE UNIVERSITY OF LOUISIANA,
NEW ORLEANS.

Faculty.—T. G. Richardson, M. D. (Dean), General and Clinical Surgery; Samuel M. Bemiss, M. D., Theory and Practice of Medicine and Clinical Medicine; Stanford E. Chaille, M. D., Physiology and Pathological Anatomy; Joseph Jones, M. D., Chemistry and Clinical Medicine; Samuel Logan, M. D., Anatomy and Clinical Surgery; Ernest S. Lewis, M. D., Obstetrics and Diseases of Women and Children; John B. Elliott, M. D., Materia Medica, Therapeutics, and Hygiene; Albert B. Miles, M. D., Demonstrator of Anatomy.

The fiftieth annual course will begin October 22, 1883, and close March 29, 1884. The Charity Hospital furnishes material for clinical and operative medicine and surgery.

Requirements for Graduation.—The ordinary requirements.

Fees.—Tickets of the professors, $140; practical anatomy, $10; matriculation, $5; graduation, $30.

For further information address T. G. Richardson, M. D., Dean, New Orleans, La.

Maine.

MEDICAL SCHOOL OF MAINE
(BOWDOIN COLLEGE, BRUNSWICK).

Faculty.—Israel T. Dana, M. D., Pathology and Practice; Alfred Mitchell, M. D. (Secretary), Obstetrics and Diseases of Women and Children; Charles W. Goddard, Medical Jurisprudence; Frederick H. Gerrish, M. D., Anatomy; Henry Carmichael, Ph. D., Chemistry; Burt G. Wilder, M. D., Physiology; Stephen H. Weeks, M. D., Surgery and Clinical Surgery; Charles O. Hent, M. D., Materia Medica and Therapeutics; Irving E. Kimball, M. D., Demonstrator of Anatomy; Everett T. Nealy, M. D., Demonstrator of Histology.

The sixty-fourth course of lectures will begin February 7, 1884, and will continue sixteen weeks. Candidates for matriculation are examined unless they are graduates of a literary institution. The examination will be held February 7th.

Requirements for Graduation.—The requirements are as usual, the examination being oral and in writing.

Fees.—Lectures, $78; matriculation (each term), $5; graduation, $25; analytical chemistry, $10.

For further information address Alfred Mitchell, M. D., Secretary, Brunswick, Me.

Maryland.

UNIVERSITY OF MARYLAND,
SCHOOL OF MEDICINE,
BALTIMORE.

The chair of chemistry is vacant, and we understand that it will not be filled this year. The lectures in that branch will be given by R. Dorsey Coale, Ph. D.

Faculty.—William E. A. Ainin, M. D., LL. D., Chemistry and Pharmacy (emeritus); G. W. Miltenberger, M. D., Obstetrics; Richard McSherry, M. D., Principles and Practice of Medicine; Christopher Johnston, M. D., Surgery (emeritus); Samuel C. Chew, M. D., Materia Medica and Therapeutics, and Lecturer on Diseases of the Throat and Chest; Frank Donaldson, M. D., Diseases of the Throat and Chest; William T. Howard, M. D., Diseases of Women and Children and Clinical Medicine; Julian J. Chisholm, M. D., Eye and Ear Diseases; Francis T. Miles, M. D., Physiology and (Clinical) Diseases of the Nervous System; L. McLane Tiffany, M. D. (Dean), sur-
gery; J. Edwin Michael, M. D., Anatomy and Clinical Surgery; I. Edwardson Atkinson, M. D., Pathology and (Clinical) Dermatology; Randolph Winslow, M. D., Demonstrator of Anatomy; Herbert Harlan, M. D., Assistant Demonstrator; J. Leigh Dorrans, M. D., H. P. Gallagher, M. D., W. B. Canfield, Jr., M. D., Prosector.

Chiefs of Clinics and Private Instructors.—II. Clinton Mooney, M. D., Diseases of the Throat and Chest; John G. Jay, M. D., Genito-Urinary Diseases; R. Dorsey Coale, C. E., Chemistry; W. P. Chunn, M. D., Diseases of Women and Children; T. W. Clark, M. D., Diseases of the Nervous System; II. Homer Hoffman, M. D., Practice of Medicine; W. B. Canfield, M. D., Surgery; Ira Woods, M. D., Dermatology; L. E. Neale, M. D., Obstetrics; I. Bernmann, M. D., Normal and Pathological Microscopic Anatomy; H. Harlan, M. D., Eye and Ear Diseases; Christopher Johnston, Jr., M. D., Joseph F. Perkins, M. D., Diseases of the Throat and Chest.

The introductory lectures begin September 29th. The seventy-sixth annual session begins October 1st, and ends about the middle of March. The university has its own hospital, embracing a lying-in department and a dispensary, together with a general hospital service.

Requirements for Graduation.—Candidates who take these courses may have their final examination in anatomy, physiology, and materia medica at the end of the second course. In other respects the requirements are as usual.

Fees.—Matriculation, $5; dissection, $10; course of lectures, $120; graduation, $30. Holders of scholarships pay only $50 for the lecture course.

For further information, address Professor L. McLane Tiffany, Dean, 137 Park Avenue, Baltimore.

Baltimore Medical College,
Baltimore.

The present collegiate year began September 5th, and will continue until April, 1884.

Students, unless matriculated of some literary institution or medical college, will be required to furnish evidence of a good English education.

Requirements for Graduation.—As usual.

Fees.—Matriculation, $5; general ticket, $120; dissection, $10; graduation, $30.

Address Dr. W. R. Monroe, Dean, 249 Bolton Street, Baltimore, Md.

Massachusetts.

HARVARD MEDICAL SCHOOL
(MEDICAL DEPARTMENT OF HARVARD UNIVERSITY)
BOSTON.

As we have before announced, Dr. Oliver Wendell Holmes has resigned the chair of anatomy, becoming professor emeritus, and Dr. Calvin Ellis has resigned the office of dean. The teaching corps now stands as follows:

Faculty.—Calvin Ellis, M. D., Clinical Medicine; Oliver W. Holmes, M. D., LL. D., Anatomy (emeritus); Henry J. Bigelow, M. D., Surgery (emeritus); Francis Minot, M. D., Theory and Practice of Physiology; John P. Reynolds, M. D., Obstetrics; Henry W. Wills, M. D., Ophthalmology; David W. Cheever, M. D., Surgery; James C. White, M. D., Dermatology; Robert T. Edes, M. D., Materia Medica; Henry P. Bowditch, M. D. (Dean), Physiology; Charles F. Folson, M. D., Assistant Professor of Mental Diseases; Frederick I. Knight, M. D., Assistant Professor of Laryngology; Charles B. Porter, M. D., Assistant Professor in Surgery; J. Collins Warren, M. D., Assistant Professor of Obstetrics; Reginald H. Fitz, M. D., Pathology; Edward S. Wood, M. D., Chemistry; William H. Baker, M. D., Assistant Professor of Gynecology; William B. Hills, M. D., Instructor in Chemistry; William F. Whitney, M. D., Curator.

Other Instructors.—Frank W. Draper, M. D., Forensic Medicine; Henry P. Quincy, M. D., Histology; Edward N. Whetter, M. D., Theory and Practice of Physiology; Francis A. Harris, M. D., Demonstrator of Medico-legal Examinations; William P. Bolles, M. D., Materia Medica; Edward H. Bradford, M. D., Clinical Surgery; Francis H. Davenport, M. D., Gynecology; George M. Garland, M. D., Clinical Medicine; Joseph W. Warren, M. D., Physiology; Maurice H. Richardson, M. D., Demonstrator of Anatomy; William W. Gannet, M. D., Pathological Anatomy; Charles S. Minot, S. D., Embryology; William C. Emerson, M. D., Chemistry; Walter J. Otis, M. D., Anatomy; Samuel J. Mixter, M. D., Anatomy; Charles Harrington, M. D., Chemistry.

Special Clinical Instructors.—John Homans, M. D., Diagnosis and Treatment of Ovarian Tumors; Francis B. Greenough, M. D., and Abner Post, M. D., Syphilis; Oliver F. Wadsworth, M. D., Ophthalmology; J. Orme Green, M. D., and Clarence J. Blake, M. D., Otology; Amos L. Mason, M. D., and Frederick C. Shattuck, M. D., Auscultation; Joseph P. Oliver, M. D., and Thomas M. Rotch, M. D., Diseases of Children; Samuel G. Webber, M. D., and James J. Putnam, M. D., Diseases of the Nervous System; James R. Chadwick, M. D., Gynecology.

The one hundred and first annual session begins Sep.
October 27, 1883, and ends on the last Wednesday in June, 1884, the intervening period being divided into two equal terms.

Except those who have passed the examination for admission to Harvard College, students will not be admitted until they have passed an examination in English, Latin, physics, and either French, German, algebra, plane geometry, or botany.

In the four years' course (recommended) the graduation is as follows: First year, anatomy, physiology, and general chemistry; second year, practical and topographical anatomy, medical chemistry, materia medica, pathological anatomy, clinical medicine, surgery, and clinical surgery; third year, therapeutics, obstetrics, theory and practice of medicine, clinical medicine, surgery, and clinical surgery; fourth year, ophthalmology, otology, pathology, syphilis, laryngology, mental diseases, diseases of the nervous system, diseases of women, diseases of children, obstetrics, clinical and operative obstetrics, clinical medicine, clinical and operative surgery, forensic medicine.

In the three years' course (required) it is as follows: First year, anatomy, physiology, and general chemistry; second year, practical and topographical anatomy, medical chemistry, materia medica, pathological anatomy, clinical medicine, and clinical surgery; third year, therapeutics, obstetrics, theory and practice of medicine, clinical medicine, surgery, clinical surgery, ophthalmology, dermatology, syphilis, otology, laryngology, mental diseases, diseases of the nervous system, diseases of women, diseases of children, forensic medicine.

Requirements for Graduation.—Students are examined at the end of each year's study, mainly in writing. The degree is still granted after three years' study, but the course of four years, with an average of seventy-five per cent. in all the examinations, entitles the candidate to the degree cum laude.

Fees.—Matriculation, $5; each year's instruction, $200; half-year, $120; graduation, $30. A few scholarships have been established.

On the 17th of October, the one hundredth anniversary of its opening, the school will occupy its new building, of the character of which our readers have already been informed. The school will comply with the requirements of the Illinois State Board of Health.

For further particulars, address Dr. H. P. Bowditch, Dean.

COLLEGE OF PHYSICIANS AND SURGEONS, BOSTON, MASS.

Faculty.—T. Haven Dearing, M. D. (Dean), Principles and Practice of Surgery; Elisha C. Chenev, M. D., Principles and Practice of Medicine; Asa F. Pattee, M. D., Materia Medica and Therapeutics; Arthur H. Wilson, M. D., Anatomy; Joshua B. Treadwell, M. D., Clinical Medicine; H. W. Dudley, M. D., Pathology; George E. Mecuen, M. D., Obstetrics; Arthur B. Morong, M. D., Physiology and Hygiene; William R. Chipman, M. D., Operative Surgery; Frederick W. Vogel, M. D., Special Pathology and Microscopy.

Lecturers on Special Subjects.—Judge E. C. Bumpus, Medical Jurisprudence; Asa F. Pattee, M. D., Diseases of the Nervous System; Roscoe E. Brown, M. D., Ophthalmology and Otology; T. Haven Dearing, M. D., Dermatology; Arthur H. Wilson, M. D., Diseases of the Genito-Urinary System; John F. Welch, M. D., Laryngology and Diseases of the Throat; Elisha C. Chenev, M. D., Gynecology and Diseases of Children; Albert J. Hahn, M. D., Instructor in Chemistry and Toxicology; Charles F. Osman, M. D., Obstetrics; Andrew F. Means, Practice of Medicine; W. H. Fals, M. D., Demonstrator of Anatomy.

The fourth annual course will begin October 10, 1883, and end May 14, 1884.

Requirements for Graduation.—Besides the ordinary requirements, candidates must have dissected at least three parts, fulfilled all the requirements of laboratory work, and maintained good deportment.

Fees.—Matriculation, yearly, $5; tickets for the full course, $85; demonstrator's ticket, $5; anatomical material, for each part, $2 or $4. A deposit of $5 will be required of each student in the chemical laboratory to cover actual cost of chemicals and breakage. Graduation fee, $30. Fee for the entire three years' tuition, including matriculation and graduation, $225, when paid in advance. Graduates of other regular schools, or those who have attended three full courses of lectures in other recognized colleges, will be allowed to attend one course, or more if they desire, and graduate for a fee of $75. Instruction in single branches, $20 a year for each branch. This includes the matriculation fee.

For further information address T. Haven Dearing, M. D., Dean, Brantree, Mass.

UNIVERSITY OF MICHIGAN, DEPARTMENT OF MEDICINE AND SURGERY, ANN ARBOR.

The following changes have been made during the year: Dr. J. N. Martin has been made assistant in surgery, Dr. C. M. Frye in materia medica and ophthalmology, and Dr. O. F. Chadbourne (secretary) in medicine. A course in comparative embryology has been added, also a special course of demonstrations in physiology.

Faculty.—Alonzo B. Palmer, M. D., LL. D. (Dean), Pathology, Practice of Medicine, and Clinical Medicine; Cobyden L. Ford, M. D., LL. D., Anatomy; Albert B. Prescott, M. D., Organic and Applied Chemistry and Pharmacy; George E. Frothingham, M. D., Materia Medica and Ophthalmology; Donald MacLean, M. D., Surgery and Clinical Surgery; Edward S. Dunster, M. D., Obstetrics and Diseases of Women and Children, and Clinical Gynecology; John W. Langley, M. D., General Chemistry; Henry Sewall, B. S., Ph. D., Physiology; William J. Herdan, Ph. B., M. D., Pathological Anatomy and Demonstrator of Anatomy; Victor C. Vaughan, Ph. D., M. D., Physiological and Pathological Chemistry, and Materia Medica and Therapeutics (Associate); Charles H. Stowell, M. D., Histology and Microscopy.
Other Instructors.—George A. Hendricks, M. D. (Curator), Anatomy; Osbourne F. Chadbourne, M. D. (Secretary), Assistant in Medicine; Charles M. Frye, M. D., Assistant in Materia Medica and Ophthalmology; Louis Hall, M. D., Assistant in Microscopy and General Histology; James N. Martin, M. D., Assistant in Surgery; Hucu Lupsinski, Ph. G., M. D., Lexa C. Leland, M. D., Assistant Demonstrators of Anatomy.

The thirty-fourth annual course begins October 1st, and closes late in June. Except graduates and matriculates in letters, applicants for admission must pass a preliminary examination. Both men and women are admitted to the classes. The three years’ course is graded as follows: First year, human and comparative anatomy, embryology, histology, physiology, chemistry, and materia medica and therapeutics; second year, continuation in review of anatomy, histology, physiology, chemistry, and materia medica and therapeutics, with pathology and practice of medicine, surgery, and obstetrics; third year, practice of medicine, surgery, obstetrics and diseases of women and children, ophthalmology and otology, with clinical medicine and surgery, and clinical gynaecology. There is an optional course in physiological and pathological chemistry, and another in toxicology. The men and women disseat in separate rooms, and the professors exercise their discretion about giving lectures and demonstrations to the two sexes apart, but most of the instruction is in common. The examinations are held at the end of each year, part of in writing.

Requirements for Graduation.—These include practical anatomy and practical chemistry. No Thesis is required.

Fees.—Matriculation, $10 for residents of Michigan, $25 for others; annual course, $25 for residents, $35 for others; graduation, $10; anatomical material for the whole course, $20. The annual laboratory expenses average less than $20.

This college will fulfill the requirements of the Illinois State Board of Health. Address Professor A. B. Palmer-Dean.

MICHIGAN COLLEGE OF MEDICINE,
DETROIT, MICH.

J. J. Mulheron, M. D., has resigned, and his chair has been filled by Duncan McLeod, M. D.; E. P. Anderson, M. D., has resigned, and J. D. Munson, M. D., has been appointed to fill the vacancy; a clinical hospital has been established in the college building.

Faculty.—Henry F. Lyster, M. D. (President), Principles and Practice of Medicine; William Brodie, M. D., Clinical Medicine; James B. Book, M. D. (Registrar), Principles and Practice of Surgery and Clinical Surgery; William C. Gustin, M. D., Obstetrics, Clinical Midwifery, and Diseases of Children; Daniel La Ferte, M. D. (Secretary), Anatomy, Orthopedic Surgery, and Clinical Surgery; C. Henri Leonard, M. D., Diseases of Women and Clinical Gynecology; Charles Douglas, M. D., Diseases of Children and Clinical Medicine; J. E. Clark, M. D., General Chemistry and Physics; Charles C. Yemans, M. D., Genito- Urinary Diseases, and Diseases of the Skin; Charles J. Lundy, M. D., Diseases of the Eye, Ear, and Throat; William C. Maybury, Esq., Medical Jurisprudence; C. A. Devenport, M. D., Clinical Obstetrics, and the Puerperal Diseases; H. C. Wyman, M. D., Physiology and Histology; Duncan McLeor, M. D., Institutes of Medicine, Materia Medica, and Therapeutics; James D. Munson, M. D., Lecturer on Diseases of the Nervous System; F. W. Owen, M. D., and W. N. Meredith, M. D., Demonstrators of Anatomy; E. A. P. Riky, M. D., Instructor in Microscopy.

The fourth annual session began September 4, 1883, and will continue six months. The three years’ course is graded as follows: Freshman year, anatomy (osteology), chemistry (inorganic), theoretical and practical, physiology (of digestion), materia medica and therapeutics; junior year, physiology (of nutrition), chemical physics, institutes of medicine, therapeutics, gynaecology, general and surgical anatomy, principles of surgery, principles of medicine and pathology; senior year, practice of medicine, clinical medicine, surgery and clinical surgery, clinical gynecology, obstetrics and gynaecology, otology, ophthalmology, laryngology, medical jurisprudence, dermatology, genito-urinary diseases, topographical anatomy. Students who are not in possession of the degree of a college or university, or of a certificate from a high school or other recognized educational institution, will be required to pass a satisfactory examination for admission. Students who have been admitted to other medical colleges, whose standard of matriculation is recognized by this college, will be matriculated without examination.

The requirements for graduation are as usual.

Fees.—Matriculation, $5; regular session, $50; preliminary (optional) term, $5; graduation, $20. Chemical and anatomical material “at reasonable rates.”

Address James B. Book, M. D., Registrar, 303 Jefferson Avenue, Detroit, Mich.

MINNESOTA COLLEGE HOSPITAL,
MINNEAPOLIS.

Faculty.—F. A. Dunsmoor, M. D. (Dean), Surgery; G. F. French, M. D., Obstetrics; A. W. Abbott, M. D., Anatomy; A. J. Stone, M. D., Diseases of Women; John Felton, Ph. D., M. D., Diseases of the Eye and Ear; Charles A. Wheaton, M. D., Clinical Surgery; W. H. Byford, Jr., M. D., Physical Diagnosis; T. F. Quinby, M. D., Materia Medica and Therapeutics; JAY OWENS, M. D., Theory and Practice of Medicine; C. I. Wells, M. D., Diseases of Children; C. H. Hunter, M. D., Histology and Pathology; Talbot Jones, M. D., Physiology; H. J. Burtwash, M. D., Clinical Medicine and Hygiene; W. S. Lyon, M. D., Toxicology; Charles W. Drew, Ph. B., M. D., Chemistry; C. E. Riggs, M. D., Nervous Diseases; James Quinn, M. D., Genito-Urinary Diseases; S. S. Westworth, M. D., Dermatology; M. M. Friselle, M. D., D. D. S., Medical and Surgical Dentistry; A. B. Cates, M. D. (Adjunct), Obstetrics; the Hon. Eugene M. Wilsson, Medical Jurisprudence; A. R. Brackett, M. D., Demonstrator of Anatomy.
The third regular session will begin October 1, 1883, and will continue five months. There is also a Spring, or Reading and Recitation Term, which begins in April, 1884.

Before matriculation the student must pass an examination in the common English branches, including reading, writing, spelling, grammar, geography, arithmetic, United States history, and so much of physics as is contained in Balfour's "Elementary Physics." Candidates having a degree in arts or sciences, or presenting a certificate from a high school or other institution in good standing, or a teacher's certificate, will be admitted without examination.

Requirements for Graduation.—Every candidate must have dissected each part of the cadaver, in addition to the ordinary requirements.

Fees.—Matriculation, $5; regular course, $50; spring term, $25.

For further information address F. A. Dansmoor, M. D., Dean, 8 Washington Avenue, South, Minneapolis, Minn.

Missouri.

MISSOURI MEDICAL COLLEGE,
ST. LOUIS, MO.

The secretary informs us that a practical chemical laboratory and a practical course in microscopy have been added, and that the graduation fee has been abolished and a fee for examination instituted in its stead.

Faculty.—William M. McPheters, M. D., Professor of Materia Medica and Therapeutics (emeritus); John S. Moore, M. D., Principles of Medicine and Hygiene; G. M. B. Maugh, M. D., Obstetrics and Diseases of Women; P. Gerbas Robinson, M. D., Practice of Medicine and Clinical Medicine; J. K. Badey, M. D., LL. D., Psychological Medicine, Diseases of the Nervous System, Clinical Medicine, and Medical Jurisprudence; Charles E. Michel, M. D., Ophthalmology, Histology, and Pathological Anatomy; H. Tuholske, M. D., Clinical Surgery and Surgical Pathology; Otto A. Wall, M. D., Ph. G., Materia Medica, Therapeutics, and Pharmacy; C. A. Todd, A. M., M. D., Anatomy and Diseases of the Ear and Throat; J. P. Kinsley, M. D. (Secretary), Physiology and Clinical Diseases of Children; T. F. Rewitt, M. D. (Dean), Principles and Practice of Surgery and Clinical Surgery; C. O. Curtman, M. D., Chemistry; P. V. Schenck, M. D., Clinical Lecturer on Gynecology; C. A. Todd, M. D., Demonstrator of Anatomy; Justin Steer, M. D., Assistant Demonstrator.

Assistants.—A. B. Shaw, M. D.; F. Struyker, M. D.; J. R. Lemen, M. D.; F. E. Eversole, M. D.

The forty-third annual session will begin October 1st and continue five months. The instruction is by clinical and didactic lectures, demonstrations, dissections, operations, etc. Clinics are held in the new Clinical Amphitheatre, at St. John's and the city hospitals, and at the College Dispensary. The faculty have also medical control of St. Bridget's Asylum, St. Joseph's Asylum, and St. Mary's Asylum.

Requirements for Graduation.—Besides the ordinary requirements, the candidate must have attended the dissections and clinics in this school as long as he was a student thereof.

A preliminary examination will be held in accordance with the rules of the State boards.

Fees.—Course of lectures, $60; matriculation (good until the following March), $5; dissection-room, $10; examination for degree (not returnable), $30.

For further information address T. F. Prewitt, M. D., Dean, 3718 N. Ninth Street, St. Louis, Mo.

ST. LOUIS MEDICAL COLLEGE,
ST. LOUIS, MO.

There have been added to the teaching corps professors of hygiene and medical jurisprudence, and pathological anatomy; also a lecturer on nervous diseases.

Faculty.—A. Litton, M. D., Chemistry and Pharmacy; J. B. Johnson, M. D., Principles and Practice of Medicine; E. H. Gregory, M. D., Principles and Practice of Surgery and Clinical Surgery; J. S. B. Alleyne, M. D. (Dean), Therapeutics and Materia Medica, and Diseases of Children; E. F. Smith, M. D., Clinical Medicine and Pathological Anatomy; L. C. Bosliniere, M. D., Obstetrics; G. Baumgart, M. D., Physiology; H. H. Mudd, M. D., Anatomy and Clinical Surgery; W. E. Fischel, M. D., I Hygiene and Forensic Medicine; R. Luzerking, M. D., Pathological Anatomy.

Lecturers.—John Green, M. D., Ophthalmology; W. L. Barret, M. D., Diseases of Women; J. M. Scott, M. D., Clinical Medicine; G. A. Moses, M. D., Clinical Gynaecology; N. B. Carson, M. D., Assistant to the Chair of Surgery; W. C. Glasgow, M. D., Diseases of the Chest and Laryngology; J. Friedman, M. D., Demonstrator of Chemistry; Edward Evers, M. D., Histology; John P. Bryson, M. D., Diseases of the Genito-Urinary Organs; W. A. McCandless, M. D., Frank R. Fry, M. D., Demonstrators of Anatomy; C. H. Hughes, M. D., Nervous Diseases; Harry Hodgen, M. D., Curator of the Museum.

The forty-second annual session will begin September 24, 1883, and continue until March 1, 1884. The college obtains its clinical material from the College Dispensary, the City Hospital, and the St. Louis Mullany (or Sisters') Hospital. All matriculates are required to pass an examination.

Requirements for Graduation.—Three regular courses of lectures must have been attended.

Fees.—Matriculation fee (paid but once), $5; fees for each regular term, $60. Graduates of this institution have perpetual free admission. Graduates of any accredited regular school of medicine will be charged a fee of $25 for attendance during a winter session.

This college has signified its intention of conforming to the requirements of the Illinois State Board of Health.

For further information address J. S. B. Alleyne, M. D., Dean, 3132 Washington Avenue, St. Louis, Mo.

ST. JOSEPH MEDICAL COLLEGE,
ST. JOSEPH, MO.

We are informed by the Dean that a chair of puerperal diseases and lectrureships on diseases of the nose and throat and on dermatology have been added to the college.
ST. LOUIS COLLEGE OF PHYSICIANS AND SURGEONS,

ST. LOUIS.

Faculty.—Louis Bauer, M. D., M. R. C. S. Eng. (Dean), Principles and Practice of Surgery, Clinical Surgery, and Orthopaedic Surgery; W. B. Hazard, M. D. (Registrar), General Pathology and Nervous and Mental Diseases; Algernon S. Barnes, M. D., Obstetrics and Diseases of Women; Robert M. King, M. D., Physiology, Histology, and Clinical Medicine; Leonidas H. Laidley, M. D., Gynecology; Rufus A. Vaughan, M. D., Diseases of Children; A. D. Williams, M. D., Ophthalmology and Otology; John T. Larew, M. D., Anatomy and Demonstrator of Anatomy; William G. Moore, M. D., Materia Medica, Therapeutics, and Dermatology; Joseph G. Lodes, Esq., Medical Jurisprudence; G. Wiley Broome, M. D., Clinical Surgery and Fractures and Dislocations; George W. Hall, M. D., Practice of Medicine and Clinical Medicine; Frank L. James, M. D., Chemistry and Toxicology; Waldo Briggs, M. D., Lecturer on Minor Surgery and Demonstrator of Operative Surgery; John P. Pardee, M. D., Lecturer on Hygiene and State Medicine.

The fifth annual course will begin October 8, 1883, and end March 5, 1884. There is also a preliminary course, which began September 10, 1883.

Requirements for Graduation.—Class examinations will be held by each professor at least once a week throughout the term. Annual examinations upon the subjects of the preceding course are held at the beginning of the regular session. If satisfactory, they advance the student to the next higher class and exempt him from further examination upon the branches passed. If not satisfactory, re-examination will be given at the end of the term.

Students who have attended three courses of lectures in reputable medical schools are not required to present certificates of study from a preceptor.

Candidates for the ad eundem degree must present a diploma, with evidence of practice for at least two years. Not more than two honorary diplomas will be conferred annually. Otherwise the requirements are as usual.

Fees.—Matriculation, $5; lecture tickets (including demonstrators’ fees), $50; examination fee, $25.

For further information address Professor Louis Bauer, Dean, 519 Pine Street, St. Louis.

OMAHA MEDICAL COLLEGE,
OMAHA, NEB.

Faculty.—Robert R. Livingston, M. D. (President), Principles and Practice of Surgery; Victor H. Coffman, M. D., Principles and Practice of Medicine and Clinical Medicine; George B. Ayres, M. D. (Secretary), Anatomy, Descriptive and Surgical, Cutaneous and Venereal Diseases; Samuel D. Mercer, M. D., Clinical Surgery; P. S. Leisenring, M. D., Obstetrics; Jacob C. Denise, M. D., Ophthalmology, Otology, and Laryngology; Richard C. Moore, M. D., Materia Medica and Therapeutics; A. S. V. Mansfield, M. D., Pathology and Histology; G. H. Peebles, M. D., Diseases of Children; H. P. Mathewson, M. D., Diseases of the Mind; Donald MacRae, M. D., Gynecology; W. S. Gibbs, M. D., Physiology; James Carter, M. D., Chemistry, Toxicology, and Clinical Medicine; John C. Cowin, Medical Jurisprudence; Edwin Brown, M. D., Demonstrator of Anatomy.

The third regular session will begin October 2, 1883, and close March 21, 1884. All candidates for admission must be possessed of a creditable English education. Women are admitted.

Requirements for Graduation.—Clinical instruction during the entire term of attendance; practical anatomy to the extent of having dissected all regions of the body; the complete course in practical chemistry; close attendance at all lectures.

Fees.—Matriculation, $5; lecture term, $35; dissecting ticket (material at cost), $10; graduation, $25.

Address George B. Ayres, M. D., Secretary, 1120 Farnam Street, Omaha, Neb.
New Hampshire.

DARTMOUTH MEDICAL COLLEGE
(MEDICAL DEPARTMENT OF DARTMOUTH COLLEGE),
HANNOver, N. H.

Professor O. P. Hubbard, LL. D., has resigned the chair of chemistry and pharmacy, and has been made professor emeritus. Professor E. J. Bartlett has been appointed to the chair formerly occupied by Professor Hubbard, and will teach chemistry principally by laboratory work. Prominence is given to instruction by a Recitation Term of six months, which, though optional, is urgently recommended.

Faculty.—Edwin J. Bartlett, M. D., Chemistry and Pharmacy; Jesse P. Bancroft, M. D., Mental Diseases; John Ordronaux, M. D., LL. D., Medical Jurisprudence; Carlton P. Frost, M. D. (Dean), Science and Practice of Medicine; Louis Elsberg, M. D., Laryngology; Edward S. Dunster, M. D., Obstetrics; Henry M. Field, M. D., Therapeutics and Materia Medica; William W. Seely, M. D., Ophthalmology; Phineas S. Conner, M. D., Surgery; Lyman B. How, M. D., Anatomy and Physiology; Paul F. Mende, M. D., Gynecology; William T. Smith, M. D., Assistant Lecturer on Anatomy and Physiology.

The eighty-seventh annual course began Wednesday, August 1st, and will continue sixteen weeks. In addition to the regular course, there are shorter courses by the following professors: Professor John Ordronaux, medical jurisprudence; Professor J. P. Bancroft, mental diseases; Professor W. W. Seely, ophthalmology; Professor Louis Elsberg, diseases of the throat.

Requirements for Graduation.—The candidate must, besides the usual requirements, present evidence that he has dissected all parts of the cadaver, and shall pass a written examination. No Thesis is required.

Fees.—Matriculation (paid annually), $5; for the course, $77; graduation fee (not returnable), $25; chemicals and ordinary breakage, $8; anatomical material at cost. Students who have attended two courses, one of them at this institution, may attend the third on payment of the matriculation fee; of those who have attended two courses at any other regular institution, $10 will be required in addition to the matriculation fee.

For further information address Carlton P. Frost, M. D., Dean, Hanover, N. H.

New York.

COLLEGE OF PHYSICIANS AND SURGEONS,
(MEDICAL DEPARTMENT OF COLUMBIA COLLEGE)
in the city of new york.

It is understood that Professor Dalton has retired from the chair of physiology, and that Professor John G. Curtis has succeeded him.

Faculty.—Alonzo Clark, M. D., LL. D. (President), Pathology and Practical Medicine (emeritus); Willard Parker, M. D., LL. D., Principles and Practice of Surgery (emeritus); John G. Curtis, M. D. (secretary), Physiology and Hygiene; Thomas Masters Markoe, M. D., Principles of Surgery; William Detmold, M. D., Clinical and Military Surgery (emeritus); Theodore Gailard Thomas, M. D., Clinical Gynecology; John Thomas Metcalfe, M. D., Clinical Medicine (emeritus); Henry Benton Sands, M. D., Practice of Surgery; James Woods McLane, M. D., Obstetrics, Gynecology, and Diseases of Children; Thomas Taunton Sabine, M. D., Anatomy; Charles Frederic Chandler, Ph. D., Chemistry and Medical Jurisprudence; Edward Curtis, M. D., Materia Medica and Therapeutics; Francis Delafield, M. D., Pathology and Practical Medicine; William Henry Draper, M. D., Clinical Medicine.

Clinical Professors.—Cornelius Rea Agnew, M. D., Diseases of the Eye and Ear; Abraham Jacoby, M. D., Diseases of Children; Fessenden Notte Otis, M. D., Venereal Diseases; Edward Constant Seguin, M. D., Diseases of the Mind and Nervous System; George Morewood Lipperts, M. D., Laryngoscopy and Diseases of the Throat; William Tillinghast Bull, M. D., Demonstrator of Anatomy; George Henry Fox, M. D., Diseases of the Skin; Theophile Mitchell Frudder, M. D., Director of the Physiological and Pathological Laboratory of the Alumni Association; Robert Felton Weir, M. D., Surgery; William Stewart Halsted, M. D., First Assistant Demonstrator of Anatomy; Francis Hartman Markoe, M. D., Second Assistant Demonstrator of Anatomy; George Montgomery Tuttle, M. D., Assistant to the Chair of Obstetrics.

The yearly course consists of but one session, of seven months’ duration. The seventy-sixth course begins on Monday, October 1, 1883, and lasts until about the 1st of May, 1884.

Recitations.—Teaching by recitation forms a prominent feature of the course, the classes being conducted daily by the following corps of examiners: John Green Curtis, M. D., Physiology. William Tillinghast Bull, M. D., Surgery. Edward Gerley Love, Ph. D., Chemistry. George Livingston Peabody, M. D., Practice of Medicine. Abraham Philip Zemansky, M. D., Materia Medica and Therapeutics. Edward Lasell Partridge, M. D., Obstetrics and the Diseases of Women and Children. William Stewart Halsted, M. D., Anatomy. The fee for the course is $40; for any single branch, $7. A full course counts as time spent with a preceptor.

THE STUDENTS' NUMBER.

299

Practical Instruction.—In addition to the clinics, which are free, private instruction is given as follows:

Normal and Pathological Histology and the Examination of the Urine are taught in the Physiological and Pathological Laboratory of the Alumni Association of the College of Physicians and Surgeons. Instruction is given by Dr. T. M. Prudden, Director of the laboratory, in practical normal and pathological histology, in courses of forty lessons each. Fee for each course, $20. Courses of twenty lessons are given by Dr. H. N. Heineman in the examination of the urine. Fee for the course, $10. Opportunity is afforded to a limited number of students or practitioners to make special or original investigations in the laboratory.

Operative Surgery.—Dr. Charles McBurney gives courses of fourteen lessons to classes of six students, embracing practice on the cadaver. Fee, $20.

Minor Surgery.—Dr. W. T. Bull gives courses of twelve lessons to classes of eight. Fee, $15.

Physical Diagnosis.—Dr. A. P. Zemansky gives courses of fifteen lessons to classes of three. Fee, $20.

Otology.—Dr. G. B. Heickok gives courses of twelve lessons to limited classes at the Eye and Ear Infirmary. Fee, $12.

Laryngoscopy and Rhinology.—Professor Lefferts superintends courses of twelve lessons by his clinical assistants to limited classes. Fee, $12.

The Fees for the Session are the same as at the other large colleges. A small charge is made for anatomical material—$1 for each “part.” The dissecting-room is open during the whole course.

Requirements for Graduation.—In the usual statement requiring two full courses, it is specified that the two must not have begun during the same calendar year. Three courses are recommended: the first including physics and chemistry, anatomy, and physiology; the second, all the branches taught; the third, materia medica and therapeutics, pathology and practical medicine, surgery, and obstetrics and gynecology. The faculty state that an immense majority of the students of the college follow this plan. A regular course in dissection is obligatory. Certificates of preceptorship are not accepted from homeopathic, eclectic, or other “irregular” practitioners, even if they are graduates of regular medical schools.

According to the merits of a student's examination (which may be partial, but final in the branches examined in, after two courses) and of his thesis, three results are possible: 1. He is “passed” when his thesis and examinations have been satisfactory in each and all of the seven branches. 2. He is “conditioned” when the average merit has been satisfactory, while in one or more branches he has been found deficient. In this case the candidate can proceed to his degree only on the condition that he first pass a re-examination in the deficient branch or branches, not sooner than at the next regular semi-annual examination. 3. He is “rejected” when the average merit has been unsatisfactory; in this case the candidate must be re-examined in all the seven branches, but the writing of a new thesis is rarely required.

We understand that the examinations are in writing, and that the personality of the candidate is not known when the decision is given upon his papers.

Communications may be addressed to John G. Curtis, M. D., Secretary of the Faculty, College of Physicians and Surgeons, Twenty-third Street and Fourth Avenue.

ALBANY MEDICAL COLLEGE,

ALBANY, N. Y.

Henry Hux, M. D., has been appointed lecturer on nervous diseases. In our issue of August 18, 1883, we recorded the death of Jacob S. Mosher, M. D., who occupied the chair of pathology, practice, clinical medicine, and hygiene. We are not informed that an appointment has been made to fill the vacancy caused by the death of Dr. Mosher.

Faculty.—Thomas Hux, M. D., LL. D. (Dean), Institutes of Medicine (emeritus); Samuel O. van der Poel, M. D., LL. D., Pathology, Practice, and Clinical Medicine (emeritus); Albert Van der Veer, M. D., Ph. D., Principles and Practice of Surgery and Clinical Surgery; — — — Pathology, Practice, Clinical Medicine, and Hygiene; Maurice Perkins, M. D., Chemical Philosophy and Organic Chemistry; John M. Boekelo, M. D., Materia Medica, Therapeutics, Diseases of the Throat, and Clinical Laryngoscopy; Lewis Balch, M. D., Ph. D., Anatomy; Samuel B. Ward, M. D., Ph. D., Surgical Pathology, Operative and Clinical Surgery; John P. Gray, M. D., LL. D., Psychological Medicine; James P. Boyd, M. D., Obstetrics and Diseases of Women and Children; Willis G. Teckels, M. D., Ph. D. (Registrar), Inorganic and Analytical Chemistry and Medical Jurisprudence; William Haines, M. D., Histology and Pathological Anatomy; Cyrus S. Merrih, M. D., Ophthalmology and Otology; Samuel O. Van der Poel, Jr., M. D. (Adjunct), Pathology, Practice, and Clinical Medicine; Franklin Townsend, M. D., Physiology; Frederic C. Curtis, M. D. (Adjunct), Dermatology; Henry Hux, M. D., Lecturer on Nervous Diseases; Eugene Van Slyke, M. D., Demonstrator of Anatomy.

The fifty-second winter session began September 11, 1883, and will continue until March 5, 1844. The course was lengthened four weeks with the session of 1882-83, and the spring session was abolished. The three years' course includes two full courses upon each subject, as follows: First year, anatomy, materia medica, physiology, chemistry, practical anatomy, and laboratory courses in chemistry and histology; second year, the full course of lectures, and the third year, theory and practice, surgery, obstetrics, and the allied branches.

Requirements for Graduation.—A three years' graded course of lectures in this college, or the equivalent of the first two courses thereof elsewhere, and the last course in this college; the usual requirements in addition.

The final examinations are in writing.

Fees.—Matriculation (yearly), $85; lecture tickets, $100 dissertation, $10; graduation, $25; chemical laboratory (each course), $10; laboratory course in histology (each course) $10.

This college will conform to the requirements of the Illinois State Board of Health. Address Willis G. Tucker, M. D., Registrar, 4 Lancaster Street, Albany, N. Y.
MEDICAL DEPARTMENT OF THE
UNIVERSITY OF BUFFALO,
BUFFALO, N. Y.

Dr. E. M. Moore, Professor of Surgery, has resigned, and Dr. Roswell Park has been appointed to the chair. Dr. Julius F. Miner, Emeritus Professor of Operative and Clinical Surgery, has resigned, and his work has been divided among the recently appointed special lecturers.

Faculty.—Thomas F. Rochester, M. D., Principles and Practice of Medicine and Clinical Medicine; William H. Mason, M. D., Physiology and Microscopy; E. V. Stoddard, M. D., Materia Medica and Hygiene; Charles Cary, M. D., Anatomy; Matthew D. Mann, M. D., Obstetrics and Gynecology; Rudolph A. Witthaus, M. D., Chemistry and Toxicology; Roswell Park, M. D., Lecturer on the Principles and Practice of Surgery and Clinical Surgery; Judson B. Andrews, M. D., Lecturer on Insanity; Lucien Howe, M. D., Lecturer on Ophthalmology and Otology; Mahlon B. Folwell, M. D., Lecturer on Dermatology and Syphilis; Frederick Peterson, M. D., Lecturer on Pathology; D. W. Harrington, M. D., Clinical Lecturer on Surgery; William H. Heat, M. D., Clinical Lecturer on Genito-Urinary Diseases; William C. Phelps, M. D., Demonstrator of Anatomy.

The thirty-eighth annual course will begin September 27, 1883, and will continue twenty-two weeks.

Requirements for Graduation.—The degree is conferred upon the joint recommendation of the faculty and the curators. Dissection during one course is required.

Fees.—Matriculation (annually), $85; tickets of all the professors amount to $100; perpetual ticket, $150; graduation, $25; demonstrator, $10, including material.

For further information address Charles Cary, M. D., 210 Delaware Avenue, Buffalo, N. Y.

BELLEVUE HOSPITAL MEDICAL COLLEGE,
NEW YORK.

During the year the faculty of this college have met with a serious loss in the death of Professor Van Buren, who held the chair of surgery. In the spring Dr. Joseph W. Howe resigned his position as Clinical Professor of Surgery. With these exceptions, there have been no noteworthy changes in the teaching corps, which is now constituted as follows:

Faculty.—Isaac E. Taylor, M. D. (President), Obstetrics and Diseases of Women and Children (emeritus); Fordyce Barker, M. D., LL. D., Clinical Midwifery and Diseases of Women; Benjamin W. McCready, M. D., Materia Medica and Therapeutics (emeritus); Austin Flint, M. D., LL. D., Principles and Practice of Medicine and Clinical Medicine; Frederic S. Dennis, M. D., Principles and Practice of Surgery and Clinical Surgery; Lewis A. Sayre, M. D., Orthopaedic Surgery and Clinical Surgery; Alexander B. Mott, M. D., Clinical and Operative Surgery; William T. Luse, M. D., Obstetrics and Diseases of Women and Children and Clinical Midwifery; A. A. Smith, M. D., Materia Medica and Therapeutics and Clinical Medicine; Austin Flint, Jr., M. D. (Secretary), Physiology and Physiological Anatomy; Joseph D. Bryant, M. D., Anatomy and Clinical Surgery and (Associate) Orthopaedic Surgery; R. Oden Doremus, M. D., LL. D., Chemistry and Toxicology; Edward G. Janeway, M. D., Diseases of the Nervous System and Clinical Medicine and (Associate) Principles and Practice of Medicine.

Professors of Special Departments.—Henry D. Noyes, M. D., Ophthalmology and Otology; Edward L. Keynes, M. D., Cutaneous and Genito-Urinary Diseases; John P. Gray, M. D., LL. D., Psychological Medicine and Medical Jurisprudence; William H. Welch, M. D., Pathological Anatomy and General Pathology and Demonstrator of Anatomy; J. Lewis Smith, M. D., Clinical Professor of Diseases of Children; Charles A. Doremus, M. D., Ph. D., Professor Adjunct to the Chair of Chemistry and Toxicology; Beverley Robinson, M. D., Clinical Professor of Medicine; Francis H. Bosworth, M. D., Diseases of the Throat.

Faculty for the Spring Session.—Frederick A. Castle, M. D., Pharmacology; William H. Welch, M. D., Pathological Histology; T. Herring Burchard, M. D., Surgical Emergencies; Charles S. Bull, M. D., Ophthalmology and Otology; Leroy Milton Yale, M. D., Diseases of the Joints.

The twenty-third regular session begins on Wednesday, September 19, 1883, and extends to the latter part of March, 1884. At its close, the spring session begins, and lasts until about the middle of June.

Weekly examinations are held by the faculty. These examinations (commonly called quizzes) are for the graduating class only, but all the students are allowed to be present. The examinations are free. In addition, special practical instruction is given to candidates for graduation by practical exercises in medicine, surgery, gynecology, ophthalmology, and otology. These exercises are designed especially for third-course students who have passed their final examinations in the elementary branches. They are extended, however, to all candidates for graduation, so far as practicable without preventing them from attending the didactic lectures. In addition to these practical exercises, courses of private instruction, not included in the general
curriculum, designed for graduates and under-graduates, are given as follows:

**Medical Diagnosis.**—Professor Janeway, medical diagnosis, with special reference to diseases of the chest and abdomen, private classes of fifteen. Twenty lessons, $20. Professor A. A. Smith, assisted by Dr. W. H. Katzenbach, physical diagnosis, private classes of fifteen. Twenty lessons, $20.

**Surgical Operations.**—Professor Dennis, private classes of four. Fifteen lessons, $15. Professor Mott, surgical operations, private classes of ten, $30.

**Operative Surgery and Surgical Dressings.**—Professor Bryant, private classes of six. Twenty-five lessons, $20.

**Physiological Laboratory.**—Professor Flint, Jr., receives five students into the Physiological Laboratory, who act as assistants during the winter session. The fee is $50.

**Practical Chemistry.**—The Chemical Laboratory is open to students every Saturday afternoon. Instruction is given by Professor Doremus, with the assistance of Adjunct Professor C. A. Doremus. The course comprises the chemical examination of the urine in health and disease. The fee for this course is $10.

**Diseases of the Eye and Ear.**—Professor Noyes, assisted by Dr. C. S. Bull, at the School of Ophthalmology and Otology connected with the New York Eye and Ear Infirmary. The fee for either the winter or the spring course is $30, for the separate branches, $10 each.

**Pathological Laboratory.**—Professor Welch, normal and pathological histology. About twenty-five lessons, to classes of twelve, $15.

**Diseases of the Heart, Lungs, and Throat.**—Professor Robinson, private classes of six. Twelve lessons, $12.

**Laryngoscopy and Diseases of the Throat.**—Professor Bosworth, private classes of ten. Twenty-five lessons, $10.

**Diseases of Women.**—Dr. Frederick A. Castle, private classes of two. Twelve lessons, $50.*

**Fees for the Winter Session.**—The tickets may be taken out separately, at $20 each, or all seven at once for $140. The surgery ticket covers cutaneous and genito-urinary diseases and orthopaedic surgery. The matriculation ticket, $5, must be taken before any of the lecture tickets can be had. It admits the bearer to all the clinical lectures and to the public hospitals. The dissection ticket is $10, which covers all charges for the practical study of anatomy. The graduation fee is $30. Graduates, and students who have attended two full courses, are given all the tickets except the matriculation and dissection tickets at $10 each. All the lecture tickets must be paid for at the beginning of the term.

**Requirements for Graduation.**—Candidates must be twenty-one years of age; must have studied three years, after the age of eighteen, with a regular physician, or regular physicians, in good standing, inclusive of the time spent in attending medical lectures; must have attended two full courses of lectures, the last being in this college; must present certificates of at least one course of dissections at this or some other accredited college empowered to confer the degree of M. D.; must have proper testimonials of character; and must pass a satisfactory examination in each of the seven departments of instruction—viz., practice of medicine, surgery, obstetrics, materia medica and therapeutics, physiology, anatomy, and chemistry. The examinations upon practice of medicine and surgery include diseases of the nervous system, pathological anatomy, ophthalmology, and diseases of the skin. Two full courses of lectures are absolutely required, and no period of practice is taken as an equivalent for one course.

The only courses of lectures recognized are those taken at regularly organized colleges empowered to confer the degree of M. D., the courses embracing practice of medicine, surgery, obstetrics, materia medica and therapeutics, physiology, anatomy, and chemistry. The tickets and diplomas of eclectic, homeopathic, or botanic colleges, or colleges devoted to any peculiar system of medicine, are not recognized. Certificates from preceptors who assume to be practitioners of any peculiar system of medicine, or who advertise, thus violating the code of ethics adopted by the American Medical Association, are not received.

Graduates of other accredited colleges are examined in all the departments, the same as under-graduates, and must fulfill all of the requirements demanded of under-graduates. If of three or more years’ standing, the graduate must show a certificate of membership in some society entitled to representation in the American Medical Association. Such candidates are expected to matriculate, to take out tickets for the winter session, to attend lectures during the session, and to pay the graduation fee of $30.

Third-course students who have taken graded courses at other accredited medical colleges, and present certificates from such colleges of having passed their examinations in any or all of the subjects of materia medica and therapeutics, physiology, anatomy, and chemistry, may be examined at the close of the session in those subjects only in which they have not already passed—thus enabling them to devote special attention to the practical branches; but they must take out all the tickets.

Students who have attended two full winter courses may be examined in the elementary branches, and, if successful, they will be examined at the end of the third course in the practical branches only. For this primary examination half the graduation fee must be paid, the remainder to be paid before the final examination. Between the two examinations another full course of lectures must be attended.

**Spring Session—Recitations and Lectures.**—The recitations are under the direction of Dr. H. Goldthwaite, and Professors Dennis, Welch, and C. A. Doremus. The ticket to the recitations and lectures is $40.

Communications relating to the business of the college should be addressed to the secretary of the faculty, Professor Austin Flint, Jr., Bellevue Hospital Medical College, New York City.
The Students' Number.

[New York Med. Jour.,]

The medical department of the University of the City of New York.

Since the opening of the last annual session Professor J. W. S. Arnold has retired from the actual duties of the chair of physiology and histology, but retains a connection with the faculty as professor emeritus of those branches. Professor Stimson succeeds Professor Arnold, and Dr. S. O. Van der Poel has been added to the faculty as professor of public hygiene. A considerable addition has been made to the building, rendering it now, the faculty state, the largest of its kind in the country. A dispensary has been added.

Faculty.—Alfred C. Post, M. D., LL. D. (President), Clinical Surgery (emeritus); Charles Inslee Pardee, M. D. (dean), Otology; J. W. S. Arnold, M. D., Physiology and Histology (emeritus); John C. Draper, M. D., LL. D., Chemistry; Alfred L. Loomis, M. D., Pathology and Practice of Medicine; William Darling, M. D., LL. D., F. R. C. S., General and Descriptive Anatomy; William H. Thomson, M. D., Materia Medica and Therapeutics, and Diseases of the Nervous System; J. Williston Wright, M. D., Surgery; William M. Polk, M. D., Obstetrics and Diseases of Women and Children; S. Oakley Van der Poel, M. D., LL. D., Public Hygiene; Lewis A. Stimson, M. D., Physiology and Histology, Clinical Lecturer on Surgery; Stephen M. Cullen, M. D., Clinical Surgery; A. E. McDonald, LL. B., M. D., Medical Jurisprudence and Diseases of the Mind; Herman Knapp, M. D., Ophthalmology; Fakeful D. Weiss, M. D., Practical and Surgical Anatomy; R. A. Witthaus, M. D., Physiological Chemistry; Ambrose L. Ranney, M. D., Curator of Museum; Joseph E. Winters, M. D., Demonstrator of Anatomy.

Adjunct Lecturers,—F. R. S. Drake, M. D., Practice of Medicine; N. M. Shaffner, M. D., Orthopedic Surgery; Joseph E. Winters, M. D., Diseases of Children; William C. Jarvis, M. D., Laryngology; Laurence Johnson, M. D., Medical Botany; P. A. Morrow, M. D., Dermatology.

Laboratory Instructors.—Wesley M. Carpenter, M. D., Maurice N. Miller, M. D., Franz Heuel, Jr., M. D., John B. Knapp, M. D., Leach H. Hunt, M. D., Ivin Sickles, M. D., Adolph W. Berle, B. S., William Francis Gibbs, B. S., George C. Pope, B. S., E. Eliot Harris, M. D.

The preliminary term begins on Wednesday, September 19, 1883, and extends to the beginning of the regular winter course, October 3d. The spring session begins at the close of the winter course, the middle of March, 1884, and continues for ten weeks. Only the winter course is obligatory.

Beside and Laboratory Instruction.—The graduating class is divided into sections of about twenty-five each, which receive separate instruction for one or two hours daily throughout the term.

The dissecting-room is open from the beginning of the preliminary term to the middle of May. Practical instruction in post-mortem examinations is given at Bellevue Hospital.

Evening examinations are held every week by Professors Draper, Loomis, Thomson, Darling, Wright, Polk, and Stimson. They are free to all the students.

The following optional courses of private instruction are given: Physical diagnosis, Professor Loomis; medical diagnosis, Professor Thomson; operative surgery and surgical dressing, Professor Wright; obstetrical operations and gynecology, Professor Polk; ophthalmology, Professor Knapp.

The fees for the winter session are the same as at the Bellevue Hospital Medical College. There is a fund for assisting a limited number of needy students, preferably the sons of physicians or clergymen, who pay $43 for the winter session, together with the matriculation fee. There are ten scholarships.

Requirements for Graduation.—These are practically the same as at the other large colleges. At least one course in practical anatomy must have been taken. The final examination is in writing. Students who have attended two full courses of lectures, and who have completed two years of study, may be admitted to examination in chemistry, anatomy, and physiology, and, if successful, will be examined, at the expiration of their full course of study, on practice, materia medica and therapeutics, surgery, and obstetrics.

Communications may be addressed to Professor Charles Inslee Pardee, M. D., Dean, 410 East Twenty-sixth Street.

College of Medicine,
Syracuse University,
Syracuse, N. Y.

The death of Harvey B. Wilder, M. D., lecturer on insanity, has rendered that chair vacant, but we understand that an appointment to fill it will soon be made.

Faculty.—Frederick Hyde, M. D. (Dean), Principles and Practice of Surgery; Henry D. Duda, M. D., Principles and Practice of Medicine and Clinical Medicine; Nelson Nivison, M. D., Physiology, Pathology, and Hygiene; Wilfred W. Porter, M. D., Obstetrics and Gynecology; William T. Plant, M. D. (Registrar), Diseases of Children and Clinical Medicine; Roger W. Pease, M. D., Operative and Clinical Surgery; Alfred Mercer, M. D., Minor and Clinical Surgery; Walter M. Smith, M. D., Chemistry and Botany; John VanDuvy, M. D., Ophthalmology and Otology; J. Gilbert Justin, M. D., Forensic Medicine; Gaylord P. Clark, M. D., Anatomy; ———, Lecturer on Insanity; David M. Totman, M. D., Lecturer on Physiology; A. Clifford Mercer, M. D., Lecturer on Microscopy and Histology.

Instructors.—Walter Smith, Chemistry; Frederick

302
THE STUDENTS' NUMBER.

W. Smith, M. D., Anatomy; Henry L. Elsner, M. D., Practice of Medicine; W. H. Dunlap, M. D., Materia Medica and Therapeutics.

The third of the twelfth college year will begin October 2, 1883, and end February 1, 1884. The second term will begin February 26, 1884, and continue until June 5th.

The studies of the first year are anatomy, physiology, chemistry, microscopy, histology, and botany; second year, anatomy, physiology, medical chemistry, materia medica, practice, surgery, pathology, and clinics; third year, therapeutics, practice, surgery, obstetrics, diseases of children, pathology, gynecology, forensic medicine, ophthalmology, and clinics.

Requirements for Graduation.—In addition to the usual requirements, the student must pass the regular examinations of the first, second, and third years, or present certificates of similar examinations elsewhere.

Fees.—Matriculation, $5; practical anatomy, $10; tuition for the year, $100; either term alone, $65; graduation, $25.

The college conforms to the requirements of the Illinois State Board of Health. Address William T. Plant, M. D., Registrar, Syracuse, N. Y.

LONG ISLAND COLLEGE HOSPITAL,
BROOKLYN, N. Y.

The faculty express the belief that they have succeeded better in practically uniting a medical school with a hospital than any other institution in this country, since all the instruction is given in the hospital building.

Faculty.—Samuel G. Armbr, M. D., LL. D. (Dean), Principles and Practice of Medicine and Clinical Medicine; George W. Plympton, M. D., Physics, Chemistry, and Toxicology; Corydon L. Ford, M. D., LL. D., Anatomy; Alexander J. C. Skene, M. D., Diseases of Women; Jarvis S. Wright, M. D. (Registrar), Operative and Clinical Surgery; Joseph H. Raymond, M. D., Physiology and Sanitary Science; Edward Seaman Bunker, M. D., Histology and General Pathology; John D. Rushmore, M. D., Surgery; John A. McCorkle, M. D., Materia Medica, Therapeutics, and Clinical Medicine; Charles Jewett, M. D., Obstetrics and Diseases of Children.

Lecturers on Special Subjects.—Jonathan S. Poole, M. D., Diseases of the Eye; Arthur Mathewson, M. D., Diseases of the Ear; Samuel Sherwell, M. D., Diseases of the Skin; Thomas R. French, M. D., Laryngology; Henry N. Read, M. D., Diseases of Children; Francis H. Stuart, M. D., Obstetrics; Elias H. Bartley, M. D., Physiological and Practical Chemistry; George H. Atkinson, M. D., Genito-Urinary Diseases; Frank E. West, M. D., Physical Diagnosis and Diseases of the Kidney; Edwin A. Lewis, M. D., Anatomy; John C. Shaw, M. D., Diseases of the Nervous System; ——, Medical Jurisprudence; Frank Madden, M. D., Demonstrator of Anatomy.

Lecturers of the Preliminary Term.—Joseph H. Raymond, M. D., Physiology; Edward S. Bunker, M. D., Histology and General Pathology; Jerome Walker, M. D., Diseases of Children; Francis H. Stuart, M. D., Obstetrics; George W. Cushing, M. D., Gynecology; Elias H. Bartley, M. D., Chemistry; George H. Atkinson, M. D., Principles of Surgery; Frank E. West, M. D., Principles of Medicine; Charles E. De La Vergne, M. D., Materia Medica; Henry W. Rand, M. D., Surgical Pathology; Edwin A. Lewis, M. D., Anatomy; John C. Shaw, M. D., Anatomy and Physiology of the Nervous System; Frank Madden, M. D., Demonstrator of Anatomy.

The collegiate year is divided into two terms—the preliminary and the regular term. The elementary branches are taught in the former mainly by recitations, the students being divided into three grades. At present the graded course is optional. The preliminary term begins September 19, 1883, and the regular term January 2, 1884. The annual commencement takes place May 21, 1884.

Requirements for Graduation.—In addition to the usual requirements, practical anatomy to the extent of having dissected every region of the body, and laboratory courses in chemistry, histology, and pathology. The examination is both oral and in writing. No Thesis is required.

Fees.—Yearly matriculation, $5; preliminary term, $40; regular term, $100; demonstrator's ticket, $5; graduation, $25; practical chemistry, $5.

For further information, address Dr. Samuel G. Armbr, Dean, Mansion House, Brooklyn.

WOMAN'S MEDICAL COLLEGE
OF THE NEW YORK INFIRMARY.

Faculty and Instructors.—Elizabeth Blackwell, M. D., Hygiene (emeritus); James R. Laming, M. D., Principles and Practice of Medicine (emeritus); Emily Blackwell, M. D., Obstetrics and Gynecology; Gerardus H. Wynkoop, M. D., Surgery; Mary Putnam Jacob, M. D., Materia Medica and Therapeutics; Edward H. Janes, M. D., Hygiene; Mary Wattles Faunce, M. D., Anatomy; A. R. Robinson, M. D., Histology; C. I. Dana, M. D., Physiology; Henry N. Heiser, M. D., Principles and Practice of Medicine; T. M. Cheesman, Jr., M. D., Demonstrator; S. M. Roberts, M. D., (Clinical) Diseases of Children; D. M. Stimson, M. D., (Clinical) Surgery; F. B. Bronson, M. D., (Clinical) Diseases of the Skin; A. B. Jedson, M. D., Lecturer on Orthopedic Surgery; Elizabeth M. Cushing, M. D., Lecturer Adjunct on Obstetrics; R. W. Amidon, M. D., Lecturer Adjunct on Therapeutics; W. R. Birdsall, M. D., Lecturer on Nervous Diseases; Josephine Chevalier, Lecturer on Chemistry and Laboratory Instructor; Sarah J. McNutt, M. D., Instructor in Surgery; Mary T. Bissell, M. D., Instructor in Physiology; Josephine Walter, M. D., Instructor in Practice; Grace Peckham, M. D., Instructor in Obstetrics.

The college year consists of a session of eight months,
beginning on the 1st of October and ending with the last day in May.

A preliminary examination is required of applicants who do not show a certificate from a literary institution. Students must attend three entire sessions, graded as follows: First year, anatomy, chemistry, physiology, materia medica, and practical work in the anatomical rooms and chemical laboratory; second year, the same, also histology, obstetrics, surgery, practice, therapeutics, and hygiene; third year, the latter departments continued, and practical medical work under the direction of the teachers, with clinical reports of cases attended. Students desiring to take a four-years' course will confer with the Secretary on matriculating, and be instructed how to proceed.

Requirements for Graduation.—Three winter sessions of lectures, with clinical instruction according to the course laid down; satisfactory examinations before the Faculty and Board of Examiners.

Fees.—Matriculation, $5; demonstrator's ticket, $10; professors' tickets, each $15, $105; graduation, $80.

The college complies with the requirements of the Illinois State Board of Health.

Address Mercy N. Baker, M.D., Secretary of the College, 128 Second Avenue.

Ohio.

MEDICAL COLLEGE OF OHIO, CINCINNATI.

Faculty.—W. W. Seely, M.D. (Dean), Diseases of the Eye and Ear; P. S. Conner, M.D., Anatomy and Clinical Surgery; Samuel Nickles, M.D., Materia Medica and Therapeutics and Clinical Medicine; James T. Whittaker, M.D., Theory and Practice of Medicine and Clinical Medicine; W. W. Dawson, M.D., Principles and Practice of Surgery and Clinical Surgery; T. A. Reamy, M.D., Obstetrics and Diseases of Children and Clinical Midwifery; C. D. Palmer, M.D., Medical and Surgical Diseases of Women and Clinical Gynecology; F. Forchheimer, M.D., Physiology and Diseases of Children; Joseph Ransohoff, M.D., F. R. C. S. Eng., Descriptive Anatomy and Clinical Surgery; James G. Hyndman, M.D. (Secretary), Medical Chemistry and Clinical Laryngology; Frederic Kehler, M.D., Lecturer on Pathology and Demonstrator of Histology; J. L. Cilley, M.D., Lecturer on Osteology and Demonstrator of Anatomy; Edward W. Walker, M.D., Lecturer on Morbid Anatomy and Demonstrator of Pathology; Fr. A. Roedel, Ph. D., M.D., Demonstrator of Chemistry; Charles F. Locke, M.D., Frank Caldwell, M.D., Assistant Demonstrators of Anatomy.

Assistants.—E. G. Zinke, M.D., Gynecology; Giles S. Mitchell, M.D., Obstetrics; James M. French, M.D., Practice; Frank Caldwell, Ph. D., M.D., C. W. Tange- man, M.D., Ophthalmology; B. F. Beebe, M.D., Physiology; L. J. Kroese, M.D., Descriptive Anatomy; Herman Wilpert, M.D., Materia Medica; T. R. Coffman, M.D., Surgery.

The sixty-fifth annual session will begin September 18, 1883, and continue until March 1, 1884.

Requirements for Graduation.—These are in accordance with the "Articles of Confederation" of the American Medical College Association.

Fees.—Professors' tickets, $75; matriculation, $5; dissection, $5; practical chemistry, $5; hospital tickets (each), $5; graduation, $25.

Address Professor J. G. Hyndman, Secretary, 22 West Ninth Street, Cincinnati.

CINCINNATI COLLEGE OF MEDICINE AND SURGERY, CINCINNATI.

Faculty.—R. C. Stockton Reed, M.D., Materia Medica, Therapeutics, and State Medicine; William Judkins, M.D., Principles and Practice of Medicine, and (Clinical) Genito-Urinary and Venereal Diseases; C. A. Lee Reed, M.D., Obstetrics and Gynecology, and (Clinical) Diseases of Women; George B. Orr, M.D., Principles and Practice of Surgery, and Clinical Surgery; J. H. Hazard, M.D., Physiology; John Bohllander, M.D., Chemistry and Toxicology; William A. Martin, M.D., Anatomy; M. L. Amick, M.D., Anatomy and Histology of the Nervous System; W. R. Amick, M.D., Ophthalmology and Otology; Anderson E. Ellis, M.D., Laryngology; Joseph T. Wallingford, M.D., Diseases of Children, and (Adjunct) Midwifery; W. K. Boylan, M.D., Materia Medica and Therapeutics; D. W. Clancy, M.D., D. D. S., Oral Surgery; John Reed, M.D., Demonstrator of Anatomy; John Bohllander, M.D., Demonstrator of Chemistry.

The forty-ninth regular session begins October 2, 1883, and will continue until the latter part of March, 1884. There will be no preliminary course. By an optional graded course students entering with the purpose of attending three courses may have their instruction graded so that at the end of the second session they may be examined in anatomy, physiology, chemistry, materia medica, and therapeutics; and the examination upon these, if satisfactory, will be final. In such cases, the last examination will be only upon the remaining studies.

Requirements for Graduation.—Practical anatomy will be required, and attendance at the hospital clinics at least one session.

Fees.—General ticket, $35; matriculation, $5; demonstrator's ticket (including material), $10; hospital ticket, $5; graduation, $25.

Address J. T. Wallingford, Secretary, 211 Baymiller Street, Cincinnati, Ohio.

STARLING MEDICAL COLLEGE, COLUMBUS, OHIO.

THE STUDENTS' NUMBER.

MIAMI MEDICAL COLLEGE, CINCINNATI.

Dr. W. A. Dun has been appointed teacher of histology, vice professor Joseph Eichberg, who confines himself to physiology.

FACULTY.—John A. Murphy, M. D., Clinical Medicine; W. H. Mussey, M. D., Operative and Clinical Surgery, and Surgical Diseases of Women; E. Williams, M. D., Ophthalmology, Aural Surgery, and Clinical Ophthalmology; W. Clendenin, M. D. (Dean), Descriptive and Surgical Anatomy; William H. Taylor, M. D., Obstetrics and Clinical Midwifery; Thomas H. Kearney, M. D., Principles of Surgery and Surgical Diseases; J. C. Mackenzie, M. D., Principles and Practice of Medicine; W. B. Davis, M. D., Materia Medica and Therapeutics; Byron Stanton, M. D., Diseases of Women and Children, and Clinical Gynaecology; William L. Dudley, M. D., Chemistry and Toxicology; N. P. Dandridge, M. D., Genito-urinary and Venereal Diseases; Joseph Eichberg, M. D., Physiology.

LECTURERS AND DEMONSTRATORS.—Robert Sattler, M. D., Diseases of the Eye and Ear; A. D. Bender, M. D., Laryngoscopy and Diseases of the Throat; R. D. Mussey, M. D., Surgical Dressings; John L. Davis, M. D., Pharmacy; W. A. Dun, M. D., Histology; F. W. Langdon, M. D., Anatomy and Comparative Anatomy; George M. Allen, M. D., Chemistry; Samuel M. Hart, M. D., Assistant Demonstrator of Anatomy; L. Rademacher, M. D., Pharmacist.

The twenty-third annual preliminary course began September 7th, the introductory lecture will be delivered October 2d, and the regular winter session will open October 3d and continue until March 1, 1884.

REQUIREMENTS FOR GRADUATION.—As usual, except that two courses at certain colleges of dentistry or pharmacy, preceding a course at this college, are accepted, and that courses in practical anatomy and practical chemistry are obligatory; also attendance at a clinical course at the City Hospital.

FEES.—Matriculation fee (annually), $5; regular lecture term, $75; graduation, $25; demonstrator's ticket, $5; practical chemistry, $7; practical physiology and histology, $7; single tickets, $10; hospital ticket, $5.

For further information address W. Clendenin, M. D., Dean, 136 West Seventh Street, Cincinnati.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF WOOSTER, CLEVELAND, OHIO.

FACULTY.—Leander Firestone, M. D., LL. D. (Dean), Diseases of Women; Akin C. Miller, M. D., Obstetrics and Clinical Gynaecology; Frank J. Weed, M. D. (Vice-Dean), Principles of Surgery and Didactic Surgery; Xenophon C. Scott, M. D., Ophthalmology and Optometry; J. E. Burns, M. D., Diseases of Children; Reuben A. VanC, M. D., Operative and Clinical Surgery; George Hunert, M. D., Principles and Practice of Medicine and Clinical Medicine; Theodore A. Weed, M. D., L. R. C. P. Lond., Diseases of the Chest and Physical Diagnosis; Jamison Strong, M. D., Mental and Nervous Diseases; Charles C. Arms, M. D., Anatomy; L. B. Tuckerman, M. D., Physiology; W. T. Corlitt, M. D., L. R. C. P. Lond., Lecturer on Dermatology; W. J. Sheppard, M. D., Therapeutics; J. H. Stoll, M. D., Materia Medica; William S. Schranton, M. D., Lecturer on Chemistry and Toxicology; A. J. Scott, M. D. (Adjunct), Diseases of Women; W. C. Craven, M. D., J. M. Frazer, M. D., Demonstrators of Anatomy.

The regular winter session began September 5, 1883, and will continue five months. The summer session will commence February 13, 1884, and will continue five months. Candidates for matriculation are examined unless they have academical certificates. Women are admitted.

REQUIREMENTS FOR GRADUATION.—Two dissections under some competent demonstrator. The examination is in writing. Candidates in dental surgery, or persons who have attended two full courses in any accredited dental college where the four primary branches are taught, may become candidates after attending two courses of practical and clinical instruction in this college. Graduates in pharmacy will be accredited with one year on their pupilage.

FEES.—Matriculation, $5; hospital ticket (one year), $3; demonstrator's ticket, $5; general ticket, $40; general ticket, winter session, $40; graduation, $30.

For further information, address Leander Firestone, M. D., Dean, Wooster, Ohio.

OREGON.

MEDICAL DEPARTMENT OF WILLAMETTE UNIVERSITY, PORTLAND, OREGON.

FACULTY.—William H. Watkins, M. D., Theory and Practice of Medicine; Holt C. Wilson, M. D., Principles
and Practice of Surgery; E. P. Fraser, M. D. (Dean), Diseases of Women and Children; James Browne, M. D., LL. D., Physiology and Physiological Anatomy; S. E. Joseph, M. D., Obstetrics and Psychological Medicine; C. H. Wheeler, M. D., Materia Medica and Therapeutics; J. C. Whiteaker, M. D., General and Surgical Anatomy; R. G. Rex, M. D., P. C., Chemistry; Matthew P. Deady, LL. D., Medical Jurisprudence; F. B. Eaton, M. D., Diseases of the Eye and Ear; H. Carpenter, M. D., Hygiene; Alfred Kinney, M. D., Lecturer on Genito-Urinary Diseases; H. E. Jones, M. D., Lecturer on Clinical Surgery.

The eighteenth annual course of lectures will commence November 5, 1883, and will continue twenty weeks. "Unless already a matriculate of the university, or a graduate of some respectable college, academy, or high school, every candidate shall be examined as to his previous education, and to his fitness for entering upon and appreciating the technical study of medicine." Women are admitted.

Requirements for Graduation.—One course in dissection, besides the usual requirements.

"All matriculates, in becoming such, are understood as pledging themselves to a lifelong fidelity to the code of ethics of the American Medical Association."

 Fees.—Course of lectures, $120; matriculation, $5; demonstrator's ticket, $10; graduation, $30.

This school will comply with the requirements of the Illinois State Board of Health.

For further information address Professor E. P. Fraser, Dean, Portland, Oregon.

Pennsylvania.

UNIVERSITY OF PENNSYLVANIA, DEPARTMENT OF MEDICINE, PHILADELPHIA.

Faculty.—Joseph Leidy, M. D., LL. D., Anatomy; Henry H. Smith, M. D., Surgery (emeritus); Richard A. F. Penrose, M. D., LL. D., Obstetrics and Diseases of Women and Children; Alfred Stille, M. D., LL. D., Theory and Practice of Medicine and Clinical Medicine; D. Hayes Agnew, M. D., LL. D., Surgery and Clinical Surgery; William Pepper, M. D., LL. D. (Provost), Clinical Medicine; William Goodell, M. D., Clinical Gynecology; James Tyson, M. D. (Secretary), General Pathology and Morbid Anatomy; Horatio C. Wood, M. D., Materia Medica, Pharmacy, and General Therapeutics; Theodore G. Wormley, M. D., LL. D., Chemistry and Toxicology; John Ashhurst, Jr., M. D., Clinical Surgery; Harrison Allen, M. D., Physiology.

Demonstrators and Lecturers.—Charles T. Hunter, M. D., Anatomy; Roland G. Curtin, M. D., Physical Diagnosis; Charles K. Mills, M. D., Mental Diseases and Electro-Therapeutics; J. Henry C. Simes, M. D., Pathological Histology; Adolph W. Miller, M. D., Materia Medica and Pharmacy; Joseph G. Richardson, M. D., Normal Histology; Robert Meade Smith, M. D., Experimental Physiology; John Marshall, M. D., Nat. Sc. D., Practical Chemistry; Benjamin F. Bake, M. D., Clinical Gynecology; Elliott Richardson, M. D., Clinical and Operative Obstetrics; Edward T. Buell, M. D., Clinical Medicine; J. William White, M. D., Surgery and Venereal Diseases; Harry R. Wharton, M. D., Clinical Surgery; John B. Deaver, M. D., Osteology and Syndecmology; Henry F. Forman, M. D., Morbid Anatomy, Pathological Histology, and Experimental Pathology; Edward T. Rechert, M. D., Experimental Therapeutics; George A. Piersol, M. D., William M. Gray, M. D., Normal Histology; John B. Deaver, M. D., Richard H. Harte, M. D., Thomas R. Neilson, M. D., Edmund W. Holmes, M. D., Anatomy; William Barton Hopkins, M. D., Harry R. Wharton, M. D., Richard H. Harte, M. D., Surgery; Albert L. Toboldt, M. D., Practical Pharmacy; William A. Edwards, M. D., Jedson Daland, M. D., Clinical Medicine; Francis X. Dercum, M. D., Archer N. Randolph, M. D., Physiology; Washington H. Baker, M. D., Obstetrics.

A preliminary examination is required of all who are not matriculates of a recognized college or have not been examined by a county medical society in a manner referred to in the action of the Medical Society of the State in 1878.

The following-named graduates of the school conduct the admission examinations in the several cities in which they reside: Dr. C. H. M. Mastin, Mobile, Ala.; Dr. P. V. Scheneck, St. Louis, Mo.; Dr. Joseph M. Towler, Columbus, Tenn.; Dr. Eugene A. Grisson, Raleigh, N.C.; Dr. C. D. Fishburn, Cincinnati, Ohio; Dr. E. C. Bullard, Boston, Mass.; Dr.——, San Francisco, Cal.; Dr. C. Gilman Smith, Chicago, Ill.; Dr. C. H. Boardman, St. Paul, Minn.; Dr. H. C. Dimond, Detroit, Mich.; Dr. W. S. Elkin, Atlanta, Ga.; Dr. J. W. Whitbeck, Rochester, N.Y.

The preliminary course opened September 10th. The one hundred and ninth annual winter session begins October 1st, and lasts until the early part of April. The course of instruction is graded as follows: First year, anatomy, histology, materia medica and pharmacy, general chemistry, including chemical physics, physiology, general pathology, general clinics, medical and surgical; second year, anatomy, topographical anatomy, medical chemistry, physiology, general pathology and morbid anatomy, therapeutics, theory and practice of medicine, surgery, obstetrics, general clinics, medical and surgical, special clinics (nervous diseases, diseases of the skin, eye, ear, diseases of women and children); third year, general pathology and morbid anatomy, demonstrations in morbid anatomy, therapeutics, theory and practice of medicine, surgery, obstetrics, operative surgery, minor surgery, and bandaging, diseases of women and children, gynecology, bedside instruction in practical medicine (including physical diagnosis), bedside instruction in practical surgery, clinical conference, general clinics, medical and surgical, special clinics (nervous diseases, diseases of skin, eye, ear, diseases of women and children); fourth year (voluntary), clinical medicine and physical diagnosis, including laryngology, clinical surgery, operative surgery and venereal diseases, nervous and mental diseases, electro-therapeutics, gynecology, dermatology, ophthalmology, otology, clinical and operative obstetrics. Final examinations are held in general chemistry, materia medica, and pharmacy at the end of the first year; in anatomy, medical chemistry, and
physiology at the end of the second year; in general pathology and morbid anatomy, therapeutics, theory and practice of medicine, surgery, obstetrics, and diseases of women and children at the end of the third year; and in clinical medicine, clinical and operative surgery, gynecology, clinical and operative obstetrics, laryngology, dermatology, ophthalmology, and otology at the close of the four years' course.

Requirements for Graduation.—These do not differ materially from those of the majority of schools.

Fees.—Matriculation, $5; each annual course, $150; dissecting material, $1 a "part." There is no graduation fee. Six free scholarships are obtainable by competitive examination.

The school will comply with the requirements of the Illinois State Board of Health. It has its own hospital. Address Dr. James Tyson, Secretary, box 2883, Philadelphia.

JEFFERSON MEDICAL COLLEGE,
PHILADELPHIA.
During the year Professor Wallace has been made emeritus professor, and Dr. Theophilus Parlin has succeeded him as professor of obstetrics and diseases of women and children.

Faculty.—Samuel D. Gross, M. D., LL. D., D. C. L.; George E. O'Kane, LL. D., Cantab., Institutes and Practice of Surgery (emeritus); Elderslie Wallace, M. D., Obstetrics and Diseases of Women and Children (emeritus); J. M. Da Costa, M. D., Practice of Medicine; William H. Pancost, M. D., General, Descriptive, and Surgical Anatomy; Robert E. Rogers, M. D., LL. D., Medical Chemistry and Toxicology; Roberts Bartholow, M. D., LL. D. (Dean); Materia Medica and General Therapeutics; Henry C. Chapman, M. D., Institutes of Medicine and Medical Jurisprudence; Samuel W. Gross, M. D., Principles of Surgery and Clinical Surgery; John H. Brinston, M. D., Practice of Surgery and Clinical Surgery; Theophilus Parlin, M. D., LL. D., Obstetrics and Diseases of Women and Children; William Thomson, M. D., Ophthalmology (honorary); J. Solis Cohen, M. D., Laryngology (honorary).

Demonstrators.—William S. Forbes, M. D., Anatomy; J. Ewing Means, M. D., Surgery; G. Mason Ward, M. D., Chemistry; Morris Longstreet, M. D., Pathological Anatomy; Cochran McClelland, M. D., Obstetrics, etc.; D. E. Hughes, M. D., Clinical Medicine; S. Mason McCollin, M. D., Pharmacy and Materia Medica; A. F. Brubaker, M. D., Physiology and Histology.

The preliminary session began September 10th. The fifty-ninth course of lectures begins October 1st, and ends the last of March. The spring session begins early in April, and closes on the last day of May. The college has a hospital of its own.

Requirements for Graduation.—Candidates must take the dissection ticket for at least one session. No honorary degrees are granted. In other respects, the requirements are those usually enforced.

Fees.—Matriculation, $5; full course of lectures, $140; dissection, $10; graduation, $90.

For further information, address Professor Roberts Bartholow, Dean, at the college, Tenth Street, between Chestnut and Walnut Streets, Philadelphia.

WOMAN'S MEDICAL COLLEGE OF PENNSYLVANIA,
PHILADELPHIA.

Faculty and Auxiliary Instructors.—Rachel L. Bodley, M. D. (Dean), Chemistry and Toxicology; Clara Marshall, M. D., Materia Medica and General Therapeutics; Frances Emily White, M. D., Physiology and Hygiene; Anna E. Broomall, M. D., Obstetrics; James B. Walker, M. D., Principles and Practice of Medicine; Hannah T. Crawford, M. D., Diseases of Women and Children; William H. Parlin, M. D., Anatomy; William W. Keen, M. D., Principles and Practice of Surgery; J. Gibbons Hunt, M. D., Histology and Microscopy; C. Newlin Peirce, D. S. S., Dental Physiology and Pathology; Horatio C. Wood, Jr., M. D., Lecturer on Special Subjects; Edward T. Breen, M. D., Lecturer on Pathology; Charles K. Mills, M. D., Lecturer on Nervous Diseases; Louis A. Durang, M. D., Lecturer on Dermatology; Alexander W. McCoy, M. D., Lecturer on Laryngology and Rhinology; Emily B. Du Bois, M. D., Demonstrator of Anatomy and Instructor in Materia Medica; Lucius E. Sayre, Ph. G., Demonstrator of Pharmacy; Henry F. Forman, M. D., Demonstrator of Pathology; Ida E. Richardson, M. D., Instructor in Practice of Medicine; Anna M. Fuller, M. D., Instructor in Obstetrics; Lena V. Ingram, M. D., Instructor in Surgery.

The thirty-fourth annual winter term will open October 4, 1883, and continue until March 13, 1884. The spring term will begin March 17, 1884, and continue ten weeks.

Requirements for Graduation.—Besides the usual requirements, the candidate must have taken one course of lectures on histology and on pathology; two courses in practical anatomy, having made at least one creditable dissection at each of the usual divisions of the cadaver; one course in the chemical, the pharmaceutical, and the pathological laboratories and in the practical use of the microscope; satisfactory evidence of having attended at least two courses of clinical lectures in the departments of General Medicine, Surgery, Obstetrics, and Gynecology is also required from each candidate for graduation.

Clinical reports in some one department of medicine will be accepted in lieu of a thesis.

Fees.—Matriculation, $5; professors' tickets, each, $15, $165; practical anatomy, $10; graduation, $50.

For the encouragement of capable and well-educated women whose means will not allow of the usual expenditure, a limited number of students will be admitted annually on the payment of thirty-five dollars for the session—exclusive of registration, matriculation, and graduation fee.

Address Rachel L. Bodley, M. D., Dean, North College Avenue and Twenty-first Street, Philadelphia.
MEDICO-CHIRURGICAL COLLEGE OF PHILADELPHIA.

The dean informs us that this institution gives a three years' graded course; that the classes are "quizzed" at the beginning of each lecture on the one previously given in the same branch, no outside "quiz" being sanctioned; that an auxiliary literary course is given during the spring and the early part of the summer; and that the final examination is oral and in writing.

Faculty.—George P. Oliver, M. D. (President), Principles and Practice of Surgery and Clinical Surgery; George E. Stubbs, M. D., Anatomy and Clinical Surgery; Charles L. Mitchell, Ph. D., M. D., Chemistry, Sanitary Science, and Medical Jurisprudence; William F. Waugh, M. D., Principles and Practice of Medicine and Clinical Medicine; Abraham S. Gerhard, M. D., Physiology, Pathology, and Clinical Medicine; William S. Stewart, M. D. (Dean), Obstretrics, Gynecology, and Clinical Gynecology; Frank O. Nagle, M. D., Materia Medica, Therapeutics, and Clinical Medicine.

The third winter session begins the first Monday in October, and continues six months. The preliminary term began September 3d.

Requirements for Graduation.—Attendance on three regular winter sessions, the last one at this college, including laboratory courses, two terms of dissection, instruction in operative surgery and bandaging; evidence of literary proficiency. Courses attended at sectarian colleges are not recognized. The additional requirements are like those of most other colleges.

Fees.—Freshman year (pharmacy, dentistry, minor surgery and bandaging, histology, elementary anatomy, materia medica, and elements of chemistry), $90; junior year (general anatomy, physiology, and general chemistry), $105; senior year (regional anatomy, pathology, medical and physiological chemistry, sanitary science, therapeutics, practice of medicine, surgery, and obstetrics and gynecology), $105; matriculation, $5; graduation, $50; auxiliary literary term, $35; dissecting "park," $1.

This college has signified its intention of conforming to the requirements of the Illinois State Board of Health. For further information, address Charles L. Mitchell, M. D., Secretary, 112 North Thirty-fourth Street, Philadelphia.

South Carolina.

MEDICAL COLLEGE OF THE STATE OF SOUTH CAROLINA,
CHARLESTON.

Faculty and Auxiliary Instructors.—R. A. Kinloch, M. D., Principles and Practice of Surgery and Clinical Surgery; J. P. Chazal, M. D., Pathology and Practice of Medicine, and of Clinical Medicine; Middleton Michel, M. D., Physiology; F. L. Parker, M. D., Anatomy, and Clinical Lecturer on Diseases of the Eye and Ear; J. Ford Prioleau, M. D. (Dean), Obstretrics and Gynecology; F. Peyre Porcher, M. D., Materia Medica and Therapeutics; T. Grange Simons, M. D. (Assistant), Pathology and Practice of Medicine and Clinical Medicine; A. R. Guerard, A. R. S. M., Instructor in Chemistry; R. Barnwell Rhyett, M. D., Demonstrator of Anatomy; John L. Dawson, Jr., M. D., Assistant Demonstrator and Prosector in Anatomy; George G. Kinloch, M. D., Instructor in Microscopy and Prosector in Surgery; P. Gourdin Desaussure, M. D., Assistant in Gynecology.

The fifty-fifth annual course will begin October 15, 1883, and end early in March, 1884—embracing a period of twenty weeks.

Requirements for Graduation.—These are as usual.

Fees.—Matriculation, $5; course of lectures, including demonstrator's ticket and hospital advantages, $75; graduation, $30.

Address J. Ford Prioleau, M. D., Dean, 2 Globe Street, Charleston, S. C.

Tennessee.

NASHVILLE MEDICAL COLLEGE
(MEDICAL DEPARTMENT OF THE UNIVERSITY OF TENNESSEE).

The teaching corps is as follows:

W. K. Bowling, M. D., LL. D., Deering J. Roberts, M. D., Theory and Practice of Medicine and Clinical Medicine; William G. Jones, M. D. (President), Insanity and Mental Hygiene (emeritus); Duncan Eve, M. D. (Dean), Surgery and Clinical Surgery; J. Bunnan Stephens, M. D., Obstretrics and Clinical Midwifery; T. B. Buchanan, M. D., General, Descriptive, and Surgical Anatomy (emeritus); W. D. Haagard, M. D., J. S. Cain, M. D., Gynecology and Diseases of Children; W. F. Glenn, M. D., Physiology, Genito-Urinary, and Venereal Diseases; W. G. Binh, M. D., Materia Medica and Therapeutics; Paul F. Eve, M. D., General, Descriptive, and Surgical Anatomy; W. M. Verrees, M. D., Medical Chemistry and Toxicology; William G. Brien, M. D., LL. D., Medical Jurisprudence; J. G. Sinclair, M. D., Diseases of the Eye, Ear, and Throat; Robert Russell, M. D., D. D. S., Dental Surgery; W. E. McCampbell, M. D., Demonstrator of Anatomy.

The ninth annual course begins October 1, 1883, and ends February 26, 1884. An optional introductory course began September 3d.

Requirements for Graduation.—Besides the usual requirements, dissection during the whole time of attendance.

[No. 8, Vol. 1, THE STUDENTS' NUMBER.]

Aug. 9, 1883.

T. E. E. STUDENTS' NUMBER. 309

FEES.—Matriculation, $5; full course of lectures, $75; demonstrator, $10; graduation, $25.

For further information address Duncan Eve, M.D., Dean, Nashville, Tenn.

Vermont.

MEDICAL DEPARTMENT OF THE UNIVERSITY OF VERMONT.
BURLINGTON.

Faculty.—Samuel White Thayer, M.D., LL.D. (Dean), General and Special Anatomy (emeritus); John Odoberaux, M.D., LL.D., Medical Jurisprudence (emeritus); William Darling, M.D., F.R.C.S., Anatomy; Albert Freeman, A. King, M.D., Obstetrics and Diseases of Women; Henry Dwight Holton, M.D., Materia Medica and Therapeutics; James Lawrence Little, M.D., Principles and Practice of Surgery; Asbesh Parmelee Grinnell, M.D., Theory and Practice of Medicine; Rudolph August Wittmann, M.D., Chemistry and Toxicology; J. Henry Jackson, M.D., Physiology and Microscopic Anatomy.

Professors of Special Subjects.—Robert William Taylor, M.D., Diseases of the Skin; Stephen Martinale Roberts, M.D., Diseases of Children; Adrian Theodore Woodward, M.D., Surgical Diseases of Women; Daniel Bennett St. John Roosa, M.D., LL.D., Diseases of the Eye and Ear; George Minton Garland, M.D., Thoracic Diseases; William James Morton, M.D., Diseases of the Mind and Nervous System; the Hon. Edward John Phelps, LL.D., Medical Jurisprudence; John Brooks Wheeler, Instructor in Principles and Practice of Surgery, and Assistant to the Chair of Surgery; Jacob Chase Ruthford, M.D., Demonstrator of Anatomy; J. B. Emerson, M.D., Assistant in Diseases of the Eye and Ear.

The regular term opens the first Thursday in March of each year, and continues seventeen weeks.

Requirements for Graduation.—Candidates must also pass a satisfactory examination before the Medical Faculty and Board of Medical Examiners appointed by the State Medical Society. No Thesis is required. "The only courses of lectures recognized are those taken at medical colleges recognized by the American Medical Association." "Certificates from preceptors who practice any peculiar system of medicine, or who advertise, or violate in any way the code of ethics adopted by the profession, will not be received, under any circumstances, even if the preceptors be regular graduates in medicine.”

FEES.—Matriculation (each term), $5; course of lectures, $70; graduation, $25. Students who have already attended two full courses of lectures in other regular schools are admitted on paying the matriculation fee and $23. Theological students are admitted on general ticket by paying the matriculation fee.

For further information address Samuel W. Thayer, M.D., Dean, Burlington, Vt.

Virginia.

UNIVERSITY OF VIRGINIA,
MEDICAL DEPARTMENT,
ALBEMARLE CO., VA.

We have received no answer to our letter of inquiry, and the information given in the catalogue (last year’s) is meager. The arrangement of the lectures seems to amount to a graded course.

Faculty.—James L. Cabell, M.D., LL.D., Physiology and Surgery; John Stagg Davis, M.D., Anatomy and Materia Medica: James F. Harrison, M.D., Medicine, Obstetrics, etc.; J. W. Mallet, M.D., Ph.D., F.R.S., Chemistry and Pharmacy; William B. Towles, M.D., Demonstrator of Anatomy.

The sixtieth session begins October 1, 1883, and lasts nine months.

Requirements for Graduation.—"Satisfactory attainments in all the subjects of instruction.”

The fees are not stated definitely. There are two scholarships.

MEDICAL COLLEGE OF VIRGINIA,
RICHMOND.

The following changes have taken place in the Faculty: Dr. Henry H. Levy has been appointed to the chair of Physiology and Pathology, vice Dr. Manson, resigned; Dr. M. L. James has been appointed Dean in place of Dr. J. B. McCaw, resigned; Dr. Robert H. Cowan has been appointed Adjunct to the chair of Diseases of Women and Children; Dr. George B. Johnston has been appointed to the chair of Materia Medica and Therapeutics; Dr. J. N. Upshur has been appointed Adjunct to the chair of Practice; Dr. Francis M. Bennett has been appointed Adjunct to the chair of Physiology and Pathology; and Diseases of the Eye, Ear, and Throat have been made a separate department, with Dr. Charles M. Shields as Clinical Lecturer.

Faculty.—James B. McCaw, M.D., Practice of Medicine; Robert T. Coleman, M.D., Obstetrics and Diseases of the Puerperal State; John S. Wellford, M.D., Diseases of Women and Children; J. S. Dorsey Culley, M.D., Surgery; WM. H. Taylor, M.D., Chemistry and Pharmacy; Christopher Tompkins, M.D., General and Special Anatomy; Martin L. James, M.D. (Dean), Materia Medica and Therapeutics; Henry H. Levy, M.D., Physiology and Pathology.

Adjunct Faculty.—John R. Wheat, M.D., Demonstrator of Anatomy; Charles M. Shields, M.D., Diseases of the Eye, Ear, and Throat; W. Augustus Lee, M.D., Obstetrics and Diseases of the Puerperal State; A. Spiers George, M.D., Surgery; Charles H. Chalkley, M.D., Chemistry; Armistead L. Wellford, M.D., Anatomy; Robert H. Cowan, M.D., Diseases of Women and Children; George Benjamin Johnston, M.D., Materia Medica and Therapeutics; John N. Upshur, M.D., Practice of Medicine; Francis M. Bennett, M.D., Physiology and Pathology.

The forty-sixth annual session will begin October 1, 1883, and continue until March 30, 1884.
Students are allowed to take a proficiency in the elementary branches, not as a diploma, but as a stimulus to study.

Fees.—Matriculation, $5; professors' tickets, $120; demonstrator, $10; graduation, $30; pharmacy course, $20.

For further information address M. L. James, M. D., Dean, 312 East Grace Street, Richmond, Va.

---

THE STATUS OF AMERICAN GRADUATES IN GREAT BRITAIN.

The diploma of any recognized American medical college is accepted in Great Britain and Ireland as evidence of three years' medical study by all bodies which confer the degrees of Bachelor in Medicine (M. B.), Master in Surgery (C. M.), and Doctor in Medicine (M. D.). Graduates who are Masters in Arts of certain American academic colleges, among which are Columbia, Harvard, Yale, Princeton, and Amherst, are not required to pass examinations in arts and science before proceeding to the degrees of M. B., C. M., and M. D. in the United Kingdom.

Graduates of American colleges may become Licentiates of the Royal College of Physicians of London, Edinburgh, or Dublin, by passing a satisfactory examination, without previous residence in the United Kingdom.

They may become Licentiates of the Royal College of Surgeons of London, Edinburgh, or Dublin by becoming Licentiates of one of the Royal Colleges of Physicians above mentioned, and passing a satisfactory examination, without previous residence.

For the benefit of those who do not hold a degree in arts, one of our colleges, the Bellevue Hospital Medical College, makes a special matriculation examination. This special matriculation examination is optional with the student, and will be given to all who desire it before they have attended their first course of lectures. It is not given to graduates or to those who have already attended medical lectures in this or any other medical college. The subjects for the matriculation examination are as follows: English language, including grammar and composition. Arithmetic, including vulgar and decimal fractions. Algebra, including simple equations. Geometry, first two books of Euclid. Latin translation and grammar. In addition, one of the following optional studies is required: Greek, French, German, or natural philosophy, including mechanics, hydrostatics, and pneumatics. Text-books: Latin—Cesar (De Bello Gallico), first two books; natural philosophy—Peck's Ganot, or Parker's Philosophy: Greek—first chapter of St. John's Gospel; French—first chapter of Telemaque, or Charles XII; German—Adler's Reader, 1st part.

For those who have passed this examination before attending their first course of lectures, the diplomas and the tickets of the college are recognized by the Royal College of Surgeons of England. The examination is not required of those who have already passed a matriculating examination at a medical college or a university recognized in England.

This special matriculation examination is necessary for those only who expect to present their tickets or diplomas for recognition in Great Britain. Students who desire this examination must hand in their names to the secretary within the first two weeks of the regular term.

---

Correspondence.

LETTER FROM BUFFALO.

The Medical Department of the University of Niagara.—The Post-graduate College.—Professor E. M. Moore.—Professor Roswell Park.—The Buffalo Medical Association.—A Narrow-minded Medical Club.

BUFFALO, September 4, 1883.

In the last two weeks the medical circles of Buffalo have been in a state of great excitement. As is well known, within the last few years two medical colleges have essayed to become diploma-mills of the first order, but "the sound of their grinding has become low." The first of these was known as the Mohawk College, and was homoeopathic. This was fought by the Erie County Medical Society, and its charter annulled. From its ashes, Phoenix-like, arose the Hamburg Canal College, and a sad bird it was—with a charter similar to the United States Medical College—and a few months ago the law strangled it in its infancy. We thought there had been enough of colleges. But last week the catalogue of the Medical Department of the University of Niagara was issued, which, being in some respects a meritorious institution, deserves full mention. The time seemed ripe for the establishment of another medical school, for the following reasons: The Medical Department of the University of Buffalo has sustained three great losses within a few years, viz.: the death of Professor James P. White, the gynecologist; the resignation of Professor Julius F. Miner, the well-known surgeon, because of ill-health; and, thirdly, the resignation of Professor E. M. Moore, of Rochester, from the chair of General Surgery. This has left the college practically in the hands of younger men and new-comers to the city, with the exception of Professor Rochester, who has been one of its pillars almost since its commencement, thirty-eight years ago. Hence, some of the reputable physicians of the city have determined upon the formation of a new medical school, with Dr. John Cronyn at its head. Dr. Cronyn is one of the ablest physicians of the city, and it has been his aim for a decade or more to found a school for higher education in medicine. His education is superior, his social position unapproachable, his address and manner elegant, and his knowledge of scientific medicine of the highest order. It has always been a matter of surprise to physicians in Buffalo that he has not been offered a chair in the college here, but the reason is possibly in the fact that he is a Catholic. Through the influence of Dr. Cronyn authority was given the University of Niagara, a Catholic college at Suspension Bridge, to organize a Medical Department. But the university is situated in Niagara County, and hence the following amendment to "An act to incorporate the Seminary of Our Lady of Angels" (now the University of Niagara), was brought before the Senate and Assembly, and passed:

"As Act to amend chapter one hundred and ninety of the laws of eighteen hundred and sixty-three, entitled "An act to incorporate the Seminary of Our Lady of Angels," Passed March 12, 1883.

The People of the State of New York, represented in Senate and Assembly, do enact as follows:

Section 1. Section six of chapter one hundred and ninety of the laws of eighteen hundred and sixty-three, entitled "An act to incorporate the Seminary of Our Lady of Angels," is hereby amended so as to read as follows:
THE STUDENTS' NUMBER.

SEC. 6. Whenever, in the opinion of the regents of the university, the state of literature in the said seminary, and the value of its property, according to the regulations of the said regents, shall justify the same, the said regents may, on the petition of the trustees, by an instrument under their common seal, erect the said seminary into a college with such name, and such number of trustees, and on such conditions, and with such powers and privileges conformable to law, as the said regents may deem proper, and the said college shall have the right to maintain any department of learning that is maintained by any college or university in this State, and may locate and maintain any department thereof in the county of Erie.

SEC. 2. This act shall take effect immediately.

This enabled them at once to fix the seat of the new school in Buffalo. The Niagara University is worth about $250,000, has some twelve hundred students, and the officers are as follows: Bishop S. V. Ryan, President and Chancellor; Rev. Patrick V. Kavanaugh, President of University; Rev. Michael J. Kircher, Vice-President. It will be seen at once that the trustees are all of the Roman Church. The faculty of the school is non-sectarian. With the exception of two, all the others are of Protestant denominations. The faculty and the different chairs, as well as the names of the occupants, may be seen in the following list:

JOHN CHOWNY, M. D., Professor of Principles and Practice of Medicine and Clinical Medicine (President of Faculty); THOMAS LOTHROP, M. D., Professor of Obstetrics; WILLIAM H. HEATH, M. D., Professor of Descriptive and Surgical Anatomy; AUGUSTUS R. DAVIDSON, M. D., Professor of Medical Chemistry, Physiology, and Toxicology; HENRY D. INGRAM, M. D., Professor of Gynecology and Diseases of Children; CHARLES G. STOCKTON, M. D., Professor of Materia Medica and Therapeutics; CHARLES C. F. GAY, M. D., Professor of Operative and Clinical Surgery; WILLIAM S. TREMAINE, M. D., Professor of Principles and Practice of Surgery and Clinical Surgery; CLAYTON M. DANIELS, M. D., Professor of Clinical Surgery and Adjunct Professor of Surgery; GEORGE E. FELL, M. D., Professor of Physiology and Microscopy; ALVIN A. HERBELL, M. D., Professor of Ophthalmology, Otology, and Laryngology (Secretary of the Faculty); Hon. Joseph M. Congdon, Professor of Jurisprudence; JOSE L. C. CHOWNY, M. D., Demonstrator of Anatomy.

There are some very good men among these, and a few who are very poor indeed. Certainly Buffalo does not contain any one better fitted for a teacher and professor than Dr. Crowyn, Sr. Dr. Lothrop, one of the editors of the "Buffalo Medical and Surgical Journal," will undoubtedly make a first-class instructor in his department. Dr. Heath, United States Marine Surgeon, will do well as an anatomist. Dr. Davidson, also of the "Journal" staff, has spent many years in fitting himself for such a position as he holds. Dr. Ingraham may make a good teacher, but has no particular fitness for his position, and it is the opinion of most that some one better might have been chosen. There is not a man in the faculty better adapted to teach than Dr. Stockton, a young man destined to be one of Buffalo's ablest and most honorable physicians. Dr. Gay has made himself a reputation as a surgeon, and his connection with the Buffalo General Hospital will bring in considerable material for clinics. Dr. Tremaine, of the United States Army, has had a vast surgical experience, and is an interesting and good lecturer. Dr. Daniels is a beginner, as yet unknown, but destined, I think, to be one day, through his perseverance, one of the good surgeons of the city. The professor of physiology should have been a physician, having more knowledge and experience in that department than Dr. Fell, whose opportunities have been very limited indeed. Dr. Hubbell disgraced himself once by being a member of the faculty of the disreputable and defunct Mohawk Mill. Hon. Joseph M. Congdon is an ex-Arsenbylinman and a good lawyer. Dr. Crowyn, Jr., will do well as demonstrator.

It will be seen from the foregoing that the faculty might easily have been improved, for it might have secured Dr. Pohlman as physiologist, Dr. Lucien Howe as ophthalmologist, and Professor Kellogg as histologist. But, even with the faculty as it is, they can all do thorough and good work in a noble cause if they carry out their intentions, which are honest and honorable. That these are such can be seen by the following excerpts from their catalogue:

The course of study shall be three years, and will comprise three full courses of lectures of six months each; but the faculty would earnestly recommend that students extend their studies to four years, that the practical branches may be more fully taught and understood. The course will be arranged in grades or classes, in such a manner as to advance the student progressively and systematically from one subject to another in a just and natural order.

All students, on entering the Medical Department of this University, must pass a matriculation examination in such studies as are considered necessary to fit them for the study of medicine, except students who shall produce testamentary evidence of preliminary qualification from a school or college recognized by this University, and graduates in medicine and students taking partial courses.

Students who may have attended lectures at some recognized medical school, and students of the Medical Department of this University, may be admitted to advanced standing by passing the required examinations in the studies of the preceding grades.

The Degree of Doctor of Medicine will be conferred by this University upon every candidate who has completed the prescribed course of study and passed the required examinations, and who is twenty-one years of age and of good moral character.

I quote these few lines from the announcement:

Inasmuch as there seems to be a very general desire that the standard of medical education should be made higher, and it being within the province of the University to inaugurate such a step at the outset, it hopes to obtain that patronage and support which such an advance in medical education entitles it to.

Naturally the question arises, How long will they carry out these good intentions? Will there not be a dearth of medical students with such requirements? Clinical material they do not lack, nor other means of teaching. They have the Sisters of Charity Hospital, an eye infirmary, a lying-in asylum, and the Medical and Surgical Dispensary. At least as long as Dr. Crowyn lives, the institution will hold to its chosen standard. After that it will be a question whether a Protestant faculty will be ruled by Catholic trustees.

Dr. Hopkins has expressed some doubt as to the legality of their charter, and has had some correspondence, as secretary of the Board of Censors of the Erie County Medical Society, with the Board of Regents of the New York State University. The regents, having granted the charter, naturally consider it legal, and the State laws appear to coincide with their opinion. The matter has even been taken up by the secular press, and doctors have freely vented their opinions as to the new college. Some have been in favor and some not.

There is still more cause for excitement, however, for still another new college needs mention. It is called the Postgraduate College, and the faculty is as follows:

F. Hamilton Potter, M. D., Professor of Physiology and Dean.
E. E. Stark, M. D., Professor of Obstetrics.
Willis G. Gregory, M. D., Professor of Materia Medica.
J. H. Pryor, M. D., Professor of the Principles and Practice of Medicine and Clinical Medicine.
J. W. Putnam, M. D., Professor of the Principles and Practice of Surgery.
The particular point of interest in this is that most of the professors are just far enough out of their teens to get diplomas. The object of the Post-graduate Medical School, as stated in one of the papers, is "to polish off the graduates of the other Buffalo medical schools."

The August number of the "Buffalo Medical and Surgical Journal" speaks thus of the recent loss of a distinguished professor at the Buffalo Medical College:

Another severe blow, quite unexpected and involving a loss which it will be impossible to supply, is the resignation of Professor E. M. Moore, who for many years has been a tower of strength to the college, attracting from far and near, by his eminent ability and wide reputation as a surgeon and teacher, students who have loved him for his sterling worth and unsullied private and professional character.

Professor Moore's resignation is a loss to the profession of this city as well as to the college. It is but fair to say of him that he is recognized as the ablest lecturer on surgery in this country. In the clearness of his lectures and the logical and practical arrangement of the subject-matter he presents, and his large and varied experience, Professor Moore has but few equals and no superior.

The same journal speaks quite ill-naturedly of his successor, as follows:

We learn that Dr. Roswell Park, of Chicago, has been appointed lecturer on surgery and clinical surgery in the place thus vacated. We fall to uncertain, after repeated inquiries in surgical circles, that the new appointee brings to this responsible position any very extensive experience or reputation. Dr. Park enters upon his new duties a comparative stranger, whom we do not know, and who, if he possesses the ability to fill the chair once occupied by men of such surgical eminence as Hamilton and Moore, should possess a high order of professional attainments, an extensive experience in his profession, and such skill as an operator as to make himself known and become a valuable acquisition to the profession of this city. The position is a difficult one to occupy, and will test the metal of the new incumbent.

The fact is that Professor Park is one of the rising young men of the United States. He is one of the six under-editors of the invaluable "Annals of Anatomy and Surgery," is the editor of the "Chicago Medical Weekly," and a lecturer at Rush Medical College; and Buffalo is to be congratulated upon securing so good a successor to Professor Moore. The cause of this attack is undoubtedly that the editors think the Buffalo college should long ago have had adjunct lecturers and professors in training for the higher positions. Thus the professors might now all be of home manufacture. There is undoubtedly just reason for a little displeasure at this, and no one doubts that it is a proper criticism to make. If the care had been taken to select some of the best and most ambitious of the young men to assist in the instruction, they might now have been among the most distinguished of our profession.

It was very unfortunate that Professor Park should meet with such a reception, yet it will not be long before the indigent physicians have recognized him for the ability he is known, from his reputation in Chicago and elsewhere, to possess.

There is not much going on in the medical societies. Dr. Lloyd read a paper this evening before the Buffalo Medical Association upon club-foot, giving a new theory as to its origin in the epiblast cells of the embryo. It aroused considerable discussion.

One of the medical clubs of the city, I hear, has passed a resolution that its members shall only call each other in consultation. It might well be named the Medical Trades-Union.

Miscellany.

A New Theory of Albuminuria.—At a recent meeting of the Paris Academy of Medicine, M. Semmola, of Naples ("Progrès médical," June 9, 1888), brought forward a new theory with regard to the causation of Bright's disease. This malady he regards as not essentially renal, but as consisting in a general morbid alteration of nutrition, and observes that albumin in such cases is not passed by the urine only, but by all the secretory organs. This alteration depri ves the albuminoids materials of the blood of their power of being assimilated, and so causes their excretion by the emunctories. The renal lesions ascribes to mechanical irritation of the tubules of the kidney by the constant passage of albumin through them. Albuminuria is therefore a cause, not a result, of renal disease. M. Semmola found these views on a series of experiments on animals. He injected into the blood-vessels various substances containing albumin, as white of egg, milk, and blood-serum, with the result of inducing artificial Bright's disease. White of egg was most active in this way. He has therefore concluded that the more nearly albuminoids approach the characters of serum-albumin, the less likely they are to injure the kidneys by irritation, and vice versa.—Practitioner.

Treatment of Scrofuloids in Children.—The "Journal of Cutaneous and Venersal Diseases" thus summarizes some conclusions recently published by M. Sabatier: I. The best mode of treating scrofuloids of children is by scraping followed by the thermo-cautery. Scraping removes the diseased tissue, and cautization completes the work by destroying the pathological elements which have survived the former process, and by setting up a benign and reparative inflammation. II. After every operation for scrofuloid of the limbs, an airtight dressing (transimont par occlusion) with strips of diachylon plaster will be found of great advantage by repressing the tendency to exuberant granulations. The sore heals more rapidly, and the resulting cicatery is thinner and more flexible than when the usual bandages are employed. III. This kind of dressing, however, is almost impossible of application on the face and neck. IV. Local treatment of a scrofuloid should always be resorted to in aid of constitutional measures. Only the former will avail to arrest a suppurating process which has lasted for several years. Without local treatment, too, the patient is liable to be more or less disfigured by the cicatrical keloids, which will inevitably be produced. It is in cases of tuberculous scrofuloid, against which the best-directed constitutional treatment is generally powerless, that local measures are of the greatest utility. By destroying the tubercules at the outset of their development, we effectually check the progress of the evil.

Army Intelligence.—Official List of Changes of Officers serving in the Medical Department of the United States Army from September 1, 1883, to September 8, 1883.—Shufelpt, Robert W., Captain and Assistant Surgeon. Granted leave of absence for three months on sur- geon's certificate of disability, with permission to leave the Department of the South. Par. 3, S. O. 204, A. G. O., September 5, 1883,—Wakeman, W. J., First Lieutenant and Assistant Surgeon. Assigned to temporary duty at Fort Sidney, Nebraska. Par. 3, S. O. 95, Department of the Platte, August 28, 1883.

Naval Intelligence.—Official List of Changes in the Medical Corps of the Navy during the week ending September 8, 1883.—Passed Assistant Surgeon Oliver Diehl, detached from the Naval Academy and ordered to the United States steamer Quinmehoung, European Station, per steamer of the 15th inst.—Passed Assistant Surgeon Frank Anderson, detached from the United States steamer Quinmehoung, on reporting of relief, and granted leave of absence for three months.
THE NEW YORK MEDICAL JOURNAL, September 22, 1883.

Original Communications.

THE CEREBRAL CORTEX.*

By AMBROSE L. RANNEY, M. D.

If a section of the cerebral cortex, in a plane vertical to that of the surface, be pressed between two thin plates of glass and then inspected by transmitted light, it will appear to the naked eye to resolve itself into secondary zones, or strata of unequal transparency. It is this peculiar appearance that has led some anatomists to describe the cortex as consisting of regularly stratified layers of alternating gray and white matter—a statement which is not supported by microscopical research. It must now be conceded that the intimate structure of the cortical substance is not the same in all parts of the brain; and that many valuable suggestions are afforded by the variations in this respect which special parts present from the type most commonly met with in the convolutions. These will be considered later.

The convolutions of the brain apparently obey some fixed law as regards their development, distribution, and the microscopical characteristics of their cortical layer. If the most prominent points of the convolutions in any given horizontal or vertical section of the adult brain be united by a curved line, it will be found that the curve described is continuous if the brain be in all respects a typical one. In old age, effects of senescence become manifest in the brain, as in the other organs. One of these is a retraction or sinking of certain convolutions, so that a continuous curve no longer unites the tips of all the convolutions over which it is described. In addition, the gray matter of the cortex becomes diminished in thickness in old age; and its color is changed to a yellowish white, on account of a transition of the cell elements into a granulo-fatty state. In certain mental diseases also, which tend to create a premature dotage, such as alcoholic poisoning, paralytic dementia, melancholic delirium, etc., we are apt to discover an atrophy of the cortical layer.

The convolutions of the brain present all varieties of configuration, not only in animals of different species, but even in the same individual. Even in homologous regions of the brain the convolutions are seldom, if ever, the same in point of outline. This can be demonstrated by laying a piece of transparent paper over a vertical section of the brain and tracing upon it the outline of the convolutions of one side as far as the median line; now double the paper over so as to cover corresponding regions of the opposite side, and no two convolutions will be found to present an absolutely identical contour. Lays states that, in his extended researches, he has never encountered a brain which was perfectly symmetrical when tested in this way. This statement has a medico-legal value— asymmetry having been thought by some neurologists to be conclusive evidence of existing disease or congenital defect.

The color of the cortex differs with age and the race. In the dark-skinned races, especially marked in the negro, it is darker than in the white man; in the babe, it is uniformly grayish and of a gelatinous consistence; in early childhood, it assumes a somewhat rosy tint; in the adult, its vascularity is apparent; in old age, it assumes a yellowish white color and loses its vascularity. The gray color of some zones as compared with others is stated by Meynert to be due to the presence of pigment within the cell elements with which the cortex is so abundantly supplied.*

The thickness of the cortical substance varies in different regions of the brain, being thicker in the anterior parts, as a rule, than in the posterior. Its average thickness may be stated to vary from two to three millimetres. Gratiolet has called attention to the curious fact that the thickness of the cerebral cortex is much less in races of small stature than in those of greater average height.

If we make thin sections of the cortex and color them with different reagents (each of which, by its chemical affini-

*We know that the medullary substance of the "island of Reil" and of the "external capsule" is here and there studded thickly with nerve-cells, which, however, fail to give it a gray appearance on account of the absence of pigment.
ty, tends to bring out some special feature in its anatomical construction, and then subject them to the magnifying power of strong objectives, we are enabled to form a clearer conception of the actual construction of the zones of unequal transparency seen by the naked eye (first brought to professional notice by Baillarger). (See Fig. 1, page 313.) By the judicious employment of gradually increasing powers in the microscopic objectives used, the general arrangement of the elements may be first mastered, and, later on, the minute details of each of the component parts may be studied.

In such research we are struck, at first, by the immense numbers of pyramidal-shaped cells* which are encountered within the cortical substance, each of which seems to point toward the surface of the brain; as if attracted toward it, like needles "so magnetized as to always point to the pole" (Luys). These are the nerve-cells; which are furthermore disposed in regular strata, parallel with the surface of the convolutions, and placed successively upon each other. It will be noticed, in the third place, that the cells grow larger as you pass from the external strata inward; † and that those of each individual layer have some distinctive peculiarities which appear to shed some light upon their function. When we come to study the characteristics of the different layers, these points will be discussed. Our attention is drawn, in the fourth place, to the fact that these cells give off branching processes which anastomose with each other, thus constituting what may be considered a continuous structure over the whole area of the convolutions. By means of these small, thread-like processes, the cells are probably enabled to communicate vibratory molecular movements from one to the other, while some are the unquestioned means also of communication between the nerve-cells and the nerve-fibers which we have previously discussed. In the fifth place, we encounter an intercellular substance, which serves to cement the cells and to maintain a fixed position for them, as well as to furnish passage for the vessels of nutrition of the cells. This is the "neuroglia," a connective-tissue formation.

We are now enabled to appreciate the analogy which Malpighi drew between the arrangement of the cells of the cortex and the seeds of the pomegranate, embedded in the white fibrous tissue which incloses them on all sides.

The nerve-fibers probably join the nerve-cells in the region of their bases; the processes given off from the spines of the cells appear to serve as a means of communication between the cells of the different layers of the cortex.

The nerve-cells, when examined as individual structures, are found to present a bright nucleus‡ and a nucleolus, and to be destitute of an investing membrane (Luys). In fresh brains, they are of an amber color. When very high powers are used, the protoplasm of the nerve-cells becomes resolved into distinct fibrille, which interlace with each other and become agglomerated in the region of the nucleus. The arrangement of these delicate fibrille has been compared by one of the most recent investigators (Luys) to the "wicker-work of an osier basket," and the same observer claims that the nucleus and nucleolus have been resolved by him into distinct secondary filaments which present a radiated appearance. I quote from him as follows: "Imagination is confounded when we penetrate into this world of the infinitely little, where we find the same infinite divisions of matter that so vividly impress us in the study of the sidereal world; and when we thus behold the mysterious details of the organization of an anatomical element, which only reveal themselves when magnified from seven to eight hundred diameters, and think that this same anatomical element repeats itself a thousand-fold throughout the whole thickness of the cerebral cortex, we can not help being seized with admiration; especially when we think that each of these little organs has its anatomy, its individuality, its minute organic sensibility; that it is united with its fellows; that it participates in the common life; and that, above all, it is a silent and indefatigable worker, discreetly elaborating those nervous forces of the psychic activity which are incessantly expended in all directions and in the most varied manners, according to the different calls which are made upon it and set it vibrating."

The neuroglia, to which we have referred in a general way as serving as a cement to fix the nerve-cells, allows

* Meynert pronounces the nerve-cells of the outer cortical layer to be distinctly star-shaped.
† They vary from 10 μ to 40 μ in height.
‡ In young subjects and in normal adult brains, the nuclei are seldom round or oval. They are usually pyramidal or spindle-shaped, running out into sharp ends. Their angles are often seen to project into the cell-processes. Arnold states that the pressure of the protoplasm of the cell tends to make the outline of the nucleus correspond to that of the cell.

**Fig. 2.** Cortical Cell of the Denser Zones at About 800 Diameters (Luys). A section of the cells made through its greater axis, its interior texture being thus laid bare. A represents the superior prolongation radiating from the mass of the nucleus itself; B, internal and posterior prolongations; C, spongy arcular substance, into which the structure of the cell itself is resolved; D, the nucleus itself seems only to be a thickening of this arcular stratum—it sometimes has a radiated arrangement; E, the bright nucleolus is itself decomposable into secondary filaments.
also of the transmission of blood-vessels into the substance of the cortex. The branches given off from the vessels of the pia mater enter the cortex upon its free surface, and immediately divide into a network of small capillary twigs, which invest the adjacent nerve-cells in an areola extremely rich in blood-vessels. In addition to these two functions, the most superficial layer of the cortex is composed largely of this connective-tissue formation, as will be seen by studying the diagrammatic drawing which I now show you.
